CLINICAL LECTURE

ON SOME OF THE RELATIONS WHICH MALARIAL AFFECTIONS AND TYPHOID FEVER BEAR TO EACH OTHER.

*Delivered at the Hospital of the University of Pennsylvania,
September 15, 1883,*

BY WILLIAM PEPPER, M.D., LL.D.,

Provost of, and Professor of Clinical Medicine in, the University of Pennsylvania.

Reported by WILLIAM H. MORRISON, M.D.

GENTLEMEN,—I shall ask you to observe with me to-day, even though in a somewhat superficial and cursory manner, several cases which are at present in the wards, for, if I do not take advantage of this opportunity, I may not soon again have the chance of presenting a group of fever-cases which illustrate in a very interesting manner, in the first place, the completely distinct character of malarial and typhoid affections; in the second place, the manner in which malarial affections sometimes resemble typhoid fever; and, in the third place, some of the ways in which typhoid fever and malarial affections may be associated. I do not intend to go into any detailed discussion of the treatment of these cases, but shall rather occupy myself in showing you, in a cursory way, the general course of the cases, and some of the general diagnostic features.

BILIOUS REMITTENT FEVER.

The first patient is W. C., 39 years of age, born in Scotland, but came to this country when a child. For four years he has been tramping about the country; his real occupation, however, being that of a boiler-maker. He has been a heavy drinker, chiefly of beer. Fifteen years ago, while in the navy, he had intermittent fever. Since that time, he has had some return of the malarial fever every fall. This tendency to return at certain periods of the year is a peculiar and characteristic feature of malarial affections. A man who has once had a severe attack of malarial fever may, although entirely cured of the original attack, exhibit in successive years, and especially during the spring and fall, a tendency to a return of the trouble. On

the 16th of August he went to work, and continued to work until the 28th of the same month. In the afternoon of this day he had a chill, followed by fever and sweating. The next morning he was chilly, with frontal headache, severe pain across the loins, nausea, vomiting, and gastric distress. He remained in bed. Since then, he has not had a regular chill, but has had irregular fever, the temperature being highest in the evening and lowest in the morning, fever, however, being always present, with derangement of the stomach and thirst. There has been no diarrhoea, no bleeding from the nose, and no delirium. He has had a great deal of headache, which has been worse in the evening when the temperature is the highest. When admitted, his temperature was 104° , the face flushed, the conjunctiva slightly yellowish, the tongue foul, with a yellow coat and disposed to be dry in the middle as he lay with his mouth open; there was no appetite; vomiting occurred whenever anything was taken into the stomach; there was a great deal of nausea, no diarrhoea, a little distention of the belly, and no eruption. The spleen was twice its normal size, but the liver was not materially enlarged. There was impaired expansion at the base of both lungs, with some gurgling râles.

There has been, then, the history of an old malarial affection, recurring every year, and of an acute attack of fever, which, when he was admitted, had lasted nine days, and which did not present the characteristic features of typhoid fever, but rather those of bilious remittent fever.

Typhoid fever comes on slowly. There are several days during which the patient feels poorly. This man had a distinct chill on the afternoon of the day on which he had felt perfectly well in the morning. In typhoid fever, there may be vomiting early, but there is no marked tendency to vomiting. There is loss of appetite, the tongue is coated, but the gastric symptoms are not severe, while, on the other hand, the belly is distended, and there is a tendency to diarrhoea. This man has had marked gastric symptoms, heavily-coated tongue, nausea, persistent vomiting, but no diarrhoea. In typhoid fever, epistaxis is common. It has not been present in this case. In the second week of typhoid fever, nervous symptoms are usually developed; there is slight wander-

ing, restless sleep, with, perhaps, delirium at night, causing the patient to leave the bed. This man has had nothing of the kind. Headache is common to both, and will not aid in the diagnosis. In typhoid fever, the spleen is enlarged, but only moderately so. It is rarely, and certainly not so early in the disease, enlarged to the extent that we find it here. About the seventh day of typhoid fever, an eruption appears. This man has had no eruption. The course of typhoid fever is not positively affected by treatment. I shall show you that we have quickly brought about a cessation of this man's fever by specific treatment.

You see, then, the marked diagnostic features which separate this case of bilious remittent fever from a case of typhoid fever.

The treatment, in brief, was as follows. On admission, he received nine grains of blue mass, followed by a laxative. This produced a moderate movement of the bowels. He then took twenty grains of sulphate of quinine a day, and immediately his fever broke, and on the second day he was entirely free from fever, the temperature being 98.4° : in other words, specific treatment produced specific results. In typhoid fever, that, or any other amount of quinine which you could give, would not bring down the fever. It would prevent it from soaring to a high point, but it would not stop it altogether. But when, encouraged by finding the temperature fall to 98° , we reduced the dose of quinia to six grains, the fever immediately went up again to 102.5° . A large dose of quinia again brought it down. The remedy was then continued in gradually diminishing doses to the present time. The man has had no fever for several days, and is now practically convalescent.

I would also remark that this man, whose system is so fully impressed with the malarial poison, will require prolonged anti-malarial treatment. I shall insist that for several months he shall take sulphate of cinchonidia conjoined with arsenious acid and iron, and that for several years to come he shall, at the approach of each spring and fall, take anti-periodic doses of cinchonidia and then continue the remedy in smaller doses for some months; and every spring and fall for four or five years after this, he shall take arsenious acid. In this way the rem-

nant of malarial poison will be eradicated from his system.

MALARIAL FEVER FOLLOWED BY TYPHOID FEVER.

Our second patient is 21 years old; was born in England, and came to this country about a year ago. Last spring, he was working in Bucks county, in a highly malarious district, and was much exposed to damp and cold. While working out in the country he felt dull, had occasional headache and costive bowels. He also states that he had a ravenous appetite. Soon after this he went to work in Darby, and was there taken sick with quotidian intermittent, and for several days he had each day a chill followed by fever and sweating. He, unfortunately, did not attend to this, and it passed into what appeared to be a remittent fever. This remittent fever being partly checked by quinia, left the man with a continued fever. It was clear that this man, whose system was impregnated with malarial poison, had contracted a mild typhoid fever. He was admitted to the hospital on September 10; on the 11th, a crop of rose-colored spots appeared on the abdomen; another crop came out on the 14th. On admission his face was flushed, there was some cough, and he was disposed to sweat. When the finger was drawn across his forehead or chest, a red streak was left; the bowels were distended, there was gurgling in the right iliac fossa, general soreness over the abdomen, the tongue was dry, brown in the centre, and tremulous; there was no appetite, but the stomach retained the light nourishment that was allowed; there has been broken sleep, but no delirium until last night; there has been no special complaint of headache; there is slight enlargement of the spleen, and congestion of the roots of both lungs, with moist râles; a faint blood-murmur is heard over the heart. His temperature has been extremely uniform for some time past, varying from 102.2° to 103.5° ; the fluctuations have not been more than three-fourths of a degree. In the previous case of remittent fever, the fluctuations were very marked. This is not to say that there may not be decided remissions in typhoid fever. The course of temperature in typhoid fever is something like the following: the person may feel poorly for four or five days, and have distinct fever, probably with a temperature of 101° ; the

next morning it may be 101.5° , in the evening it may reach 102° ; by the seventh day it will probably be about 101.5° or 102° ; for the next eight or nine days the temperature keeps mounting up, being a little higher each evening and a little lower in the morning, but not as low as on the previous morning—there may be a variation of one and a half or two degrees between the morning and the evening temperatures. During the third week the temperature is pretty uniform; during the fourth week the temperature drops in the same way as it ascended, so that by the close of the fourth week, if there is no complication, the patient is free from fever.

This man came to us with a history of an irregular fever of an uncertain duration; it is therefore difficult to say at what period of the disease we have our patient. The only thing that we can say is that he is still at the period at which eruption comes out. The detection of an eruption is a matter of the greatest importance. When you observe how the system may be affected by malaria, and then have typhoid fever grafted upon the previous disease,—when you reflect on the irregular course which remittent fever pursues, and when we come to see how closely catarrhal fever may imitate typhoid, you will recognize that the finding of an eruption is, as I have said, a matter of the greatest importance. These spots are of a rose-color; they are separate; their shape is oval, and they vary in length from one-twelfth to one-sixth of an inch; they are not at all, or very slightly, elevated above the surface. Sometimes, if the touch be delicate, the finger may detect that there is a slight elevation; when pressed upon, they entirely disappear; when the pressure is taken away, they soon return. The eruption is found for the most part on the belly, and on the lower part of the chest; but I have seen it on the arms and legs when it could not be found on the belly, and have found it on the back when it existed on no other part of the body. In the vast majority of cases, however, it makes its appearance first, and often only, and continues longest, over the belly and the lower part of the thorax. It usually makes its first appearance about the seventh day of the disease; it does not all come out at once, but it appears in successive crops; there may be five or six or fifteen or twenty spots in

each crop. The spots continue to come out as long as the disease is in actual progress; as a rule, no more come out after the end of the third week, unless the case is going to be an irregular and prolonged one.

In a case like the present one, in which there is a distinct history of a malarial fever, followed by an irregular sort of remittent fever which has continued to the present time, the question to be decided is whether this man has remittent or typhoid fever. The onset was like that of malarial fever. There has been very little gastric disturbance. There has been delirium. The remissions have not been so marked as in the previous case of remittent fever. There has been continued fever. The man has had a cough, but this might exist in remittent fever. There has been no epistaxis; he has not had distention of the belly, nor diarrhoea; but none of these are constant in typhoid cases. If we had any doubt as to the diagnosis, we certainly had none after we found the specific eruption.

In examining the abdomen of a patient for the typhoid eruption, you will, particularly in hospital patients, often find other eruptions which are not to be confounded with that due to typhoid fever. There may be little pimples; these are papular and elevated above the skin. There may be an eruption due to the bites of mosquitoes, fleas, bedbugs, or other insects; these all have a little central opening, where the irritating matter was deposited. They are elevated, do not entirely disappear on pressure, and are not rose-colored.

This patient is passing through an ordinary mild case of typhoid fever. His temperature has never been above 103.5° ; there have been no severe nervous symptoms, no profuse epistaxis, and no vomiting. To-day he has a copious perspiration, and I think that this will be a short case of typhoid fever.

In the treatment of this patient we have not employed the large doses of quinia which we did in the previous man, for they would have had no specific effect. He has, however, received a larger amount than he otherwise would, because he has had malaria. He has taken twelve grains of quinia, with mineral acid, every day, receiving two grains of quina sulphate and five drops of dilute hydrochloric acid every four hours. He has been kept in bed, and has been given an absolutely liquid diet. As you know,

there is in this disease ulceration of the lower part of the small intestine, and if irritating or indigestible articles of food are given, perforation and death may ensue even in mild cases; so that the study of the course of the disease and a recognition of its true character is not only a matter of interest, but may be a question of life or death to the patient. So important is this that if I were not quite certain as to the nature of the disease I should put the man on large doses of quinine, as a therapeutic test, and continue it for two or three days. If a rapid fall in the temperature to 98° did not take place, I should treat the case as one of typhoid fever. It is in these mild cases particularly that the friends of the patient are anxious that he should be allowed to get out of bed and take injudicious articles of food. If you yield to their solicitations, the patient may have a sudden pain in the right side, enormous distention of the belly, a running pulse, constant vomiting, and be dead within twelve hours. It is in these mild cases that indiscretions in diet are more likely to be allowed, and therefore it is that a study of the diagnosis is doubly important.

UNCOMPLICATED TYPHOID FEVER.

Our next patient, M. L., is a Russian, 22 years of age. He came to America three years ago. His history and habits are good, but he lives in a very malarious district. Three years ago, he suffered from sunstroke, but recovered. Two years ago, he had a severe attack of intermittent fever, lasting for six months. Two weeks before admission, he began to feel heavy, dull, indisposed to work, had vague pains, occasional bleeding of the nose, and failure of appetite. The symptoms gradually became more marked until the 25th of August, when he felt very ill, had headache, complete loss of appetite, and his bowels were purged to an unusual extent by a small dose of laxative. This was followed by diarrhoea. He continued to grow worse, and was brought to the hospital on the last day of August and about the eleventh day of the disease. He had all the symptoms of typhoid fever.

On admission, he was given quinine and dilute hydrochloric acid. He was put to bed, given a liquid diet and one or two small doses of opiates. Under this treatment the man has progressed in the most satisfactory manner. On admission, his temperature was 105° . The remissions

were very marked, sometimes being as much as three degrees between the morning and evening temperatures. The temperature has steadily come down. On September 5 the temperature was 101° , and on the 8th, the twentieth day of the disease, it was down to normal for the first time. On one day there was a rise to 100° ; but practically he has been free from fever for about a week.

This has been an uncomplicated case of typhoid fever, with a slow onset, with vague symptoms, lassitude, increasing debility and loss of appetite, occasional epistaxis, headache; then more marked fever, and finally such debility that he had to go to bed, and then appeared the fully-developed train of symptoms. This case has run a mild and perfectly satisfactory course, terminating in recovery at rather an early period. Although this man has been watched very carefully since admission, we have been unable to discover any eruption. It is possible that the eruption may have been present and disappeared before he was brought here; but with a history so distinct as this was we did not need the eruption to make the diagnosis. Let me here impress upon you the fact that the eruption, although a very characteristic and a very common symptom, is not absolutely necessary; and, indeed, there is no symptom in any disease that is absolutely necessary. The eruption occurs in perhaps ninety or ninety-five per cent. of all cases of typhoid fever. It is peculiar in the fact that mild cases may have the most eruption. I have seen a person, with the mildest form of typhoid fever, covered from head to foot with rose-colored spots; and, on the other hand, I have seen patients with severe and even fatal typhoid fever, with extensive intestinal ulceration, in whom the eruption was but slight. The amount of eruption bears no direct relation to the severity of the disease.

TYPHOID FEVER FOLLOWED BY MALARIAL FEVER.

Lastly, I shall show you a woman whose case has been a very interesting one. She was born in Ireland, and has been in this country only two months. She lives in this city. There has been no special sickness in the neighborhood where she lives. She has had all the fevers of childhood, except scarlet fever. She was admitted on August 15, and then stated that she had been taken sick five days previously.

She would now be at about the thirty-sixth day of her disease. The attack began with the well-recognized symptoms of typhoid fever, and followed a period of indisposition and weakness, with aching in the bones, and a little vomiting. On admission, the face was flushed, there was a yellow tinge to the conjunctivæ, the mind was dull, the belly distended, the tongue red and dry, and glazed rather than coated; no appetite, a great deal of pulmonary congestion, with moist bronchial râles everywhere, but no pneumonia; there was no eruption. She had irregular chilly feelings, with flushes of heat, but the fever continued pretty steadily; epistaxis recurred; the bowels were quiet, but when a small dose of a laxative was given she had eight loose, yellow stools. This illustrates a point in typhoid fever, that is, although there may be no actual diarrhœa, yet there is irritability and sensitiveness of the bowels; so that you may make use of this therapeutic test in cases in which there is doubt. In remittent fever, the bowels are usually, although not always, not only quiet but constipated, so that small doses of a laxative produce no effect.

The temperature on admission was 103° , and the pulse 120. This was, then, an ordinary case of typhoid fever. About the twentieth day of the disease, the fever began to fall, and by the twenty-third day the morning temperature was 99° , but in the evening it went up to 102° or 102.5° . The fluctuations between morning and evening were very marked, sometimes as much as four degrees. I should have stated that in the fourth week of typhoid fever there are marked vacillations in the temperature; but this is more than common. On the morning of September 5, the twenty-seventh day of the disease, the temperature was 98° , in the evening 101° ; the next morning it was 98° , that evening, 101° ; next morning 98.5° , evening, 99° ; the succeeding morning it was 99° , but in the evening it suddenly went up to 107° . The woman was very ill, the face was flushed, there was rapid action of the heart and excited pulse; but no local symptoms were present to explain this rapid rise. There was no pneumonia and no perforation of the bowel; a careful examination showed that this rapid rise was not dependent upon the development of any true inflammatory complication. I neglected to say that, for a few days be-

fore this, there had been a number of unhealthy-looking boils coming on her person. In a disease which is more or less putrid, as is typhoid fever, where there are a number of ulcers in the bowel throwing off infecting material, it is not impossible, and, indeed, it is not rare, to have a sort of septic poisoning, almost like pyæmia, develop. These boils suggested something of this kind. The rise of temperature was either due to pyæmia or was the result of an outbreak of malaria, or it was one of those anomalous ephemeral rises which may be found in the convalescence of a number of diseases. The course of the case soon showed that it was not pyæmic. The next morning the temperature was down to normal, and the patient was immediately placed on large doses of quinia. So far there has been no return of the fever. There was very little in this case to make one suspect that the woman was malarious; there was no history of malaria, she had only been in this country for two months, and had just come off the sea; she had not lived in a malarious district. We can, however, explain this sudden rise in no other way.

I have thus passed in rapid review these cases which illustrate some of the relations which exist between typhoid fever and malarial affections, have described the general course of the diseases, and have given you some of the diagnostic features.

ORIGINAL COMMUNICATIONS.

DIETETICS FOR THE SICK.

*Read before the Philadelphia County Medical Society,
September 12, 1883,*

BY CHARLES M. SELTZER, M.D.

IN presenting this paper it is but justice to state that it has been prepared during the leisure of the past week as a substitute for one by another member, who was unable to keep his engagement. The subject has been selected more with the hope of eliciting some practical ideas, and from the desire to emphasize its importance, than to announce anything new or to exhibit the best paces of a hobby. Close attention to the methods of our most successful general practitioners convinced me that in dietetics was their stronghold. At the same time there was plainly to be seen a distressing lack of knowledge as to variety

of foods and the preparation of them. In order to find out whether there was a practical remedy for these two great faults, I have gone over a thorough course of preparation of diet for the sick, under the instructions and guidance of Mrs. S. T. Rorer, in whom are combined the practical attributes of cook, chemist, physiologist, and nurse, and I can safely say that if every member of this Society were to do likewise, their armamentarium, success, and self-satisfaction in the practice of medicine would be increased manifold.

It would be almost an endless task to discuss the literature of this subject. Let us condense the opinions of physiologists, chemists, hygienists, and all others in authority, by stating that food is divided into nitrogenous or albuminous, hydro-carbons, or starch, sugar, and fats, and minerals or the various salts of the alkalies. Of these the nitrogenous and minerals are the building-materials, and the hydro-carbons are the heat- and force-producers. Food may also be classified into liquid, semi-solid, and solid, and, as the sum total of digestion is a matter of absorption and assimilation, it follows that the more liquid or dissolvable food is, the more readily will it be absorbed: hence this is the form to be chosen when it is desirable to obtain nourishment at the least possible expense of organic action. There are also conditions in which bulk and solidity are necessary, and here we select the semi-solid or solid food, or even indigestible matter.

Nitrogenous food, in its natural combination with mineral matters, is mostly made absorbable by stomachic digestion: it rebuilds the tissues, and the waste and refuse are excreted by the kidneys and skin as urea and uric acid and its salts.

Hydro-carbons are digested in the mouth and small intestines, are burnt up by union with the respired oxygen, thus supplying heat and force to the body. The waste and refuse are excreted by the lungs and bowels.

About three ounces of nitrogenous and twenty ounces of carbonaceous food are necessary to sustain the life of an adult man in idleness. With these epitomized facts in mind, let us consider the importance and use of dietetics in the treatment of disease. The importance has been signalized by Bence Jones, who has said that the effect of diet is far beyond any known remedy. This fact has been so well known

for the past century that volume after volume has been written on "Dietetics," "Diet Cures," etc. A few of these have become standard works of authority, because of their scientific and exhaustive treatment of the subject, while hundreds of others have had but an ephemeral existence. All have had to reiterate the same facts, because very few new ones have been learned, and, aside from the knowledge of artificially-digested food, the student of a hundred years ago knew as well as the student of to-day about what diet was necessary for the sick. True, theirs was an empirical teaching: they knew nothing of the physiological actions of diastase, pepsin, and pancreatin, but they were all the more practical for that. Our present scientific reasonings on digestion are but the formulation of rules and theories for very old facts. The importance of the subject is made more manifest when we consider how much of the sickness that we are called upon to treat is the result of some error in eating or drinking, and, as "removal of the cause" is the first step towards the promotion of recovery, it is easy to perceive how essential it is to know what constitutes proper and improper diet. Life depends upon diet, and the restoration of health depends upon the same principles as its preservation. Disease is the result of the violation of the laws of health; hence the first step towards recovery is to re-establish those laws; and, as the material for repair and support must come from diet, we, as thorough physicians, should have a complete *practical* knowledge of dietetics and a proper appreciation of their curative value. But almost a decade of experience among physicians compels me to acknowledge that this is not the case, and that the most lamentable deficiency is in the practical application of the subject. Nature's simple and easily-understood remedies are either lost sight of or ignored in the blind endeavor to find a medical specific for every human ill, or to establish an ideal notion, theory, or pathy. For the treatment of chronic affections, some good points may occasionally be gained by even observing the *modus operandi* of quacks, homœoquacks, and proprietary medicines, for in connection with either a depurative or inoperative preparation, such dietetic and hygienic directions are almost invariably *insisted* upon as would in themselves relieve tem-

porarily, and perhaps permanently, some of the most obstinate cases.

The methods of dietetic treatment of diseases are as various as are the ills that flesh is heir to, but all of them contain some of the following principles as essential features. In acute diseases, *rest* is of primary importance; it is the fundamental principle of their medical and surgical treatment, and the same idea must be carried out in dietetics by remembering what part each organ serves in absorption, assimilation, and excretion, and by avoiding such food as would cause the performance of that function. Of course this plan is only to be pursued while the disease is advancing, and as soon as recovery begins there must be a gradual return to a promiscuous diet, very little at first, just enough to slightly exercise the crippled organ, using as great care as we would in instituting passive motion in a limb that has been fractured. Nature enforces this principle by the loss of appetite that marks the onset of nearly all acute diseases. The dietetic rest of an organ does not necessarily imply a depletory diet, for, while it is non-active, other organs may be made to perform a compensatory amount of work, and thus sustain or even increase the patient's vitality,—so great is the versatility of our organic functions. It is upon this idea that we must act when we obey the command of Graves to feed fevers. In chronic diseases—those in which the natural course is direct from bad to worse, until death or some interposing process puts an end to them—every organ must be made to do its utmost; the whole system must be awakened to the threatening destruction. Herein lies the broadest field of action for our subject. No time should be lost; food should be administered as frequently as assimilation and proper amount of organic rest will allow; the appetite should be kept active, by using liquid, semi-solid, and solid food, prepared in such a variety of ways as to allow no charge of monotony or disgust. Surprise is frequently a useful element. Instead of leaving the patient to vacillate over his or her likes and dislikes, the nurse should be privately instructed how and what to prepare for each time, and how to serve it in the most appetizing manner. A valuable aid, usually lost sight of, is condiment. Think but for a moment how a savory dish will sharpen our appetites while in health, and I am

sure you will perceive its stimulating influence upon a debilitated patient, to whom the flat and insipid preparations usually offered are loathsome or even nauseating. This disgust might frequently be avoided, and the amount of prescribed medicine be lessened. Many of the bitter tonics and carminatives of our *materia medica* are the same as are used in cookery, and are none the less efficacious in a palatable dish than in the nauseous pill or draught. Therefore let the delicate aroma of herbs, celery, and bay leaves pervade the soups; use India curry on starchy foods, and when desirable add *capsicum*, *piper nigrum*, etc., to animal broths and substances. In so doing, if necessary, you can satisfy the qualms of your professional dignity by remembering that in catering to the palate you reflexly stimulate the organs of digestion.

Some articles of diet may be administered simply for their curative effect. A five-ounce cup of strong coffee contains about sixty-six grains of extract, or an equivalent of about two grains of *caffeine*,—quite sufficient to relieve a neuralgia, or a headache and sick stomach after a dose of opium. Beef-tea made red-hot with red pepper is the very best treatment for delirium tremens. A patient to whom I once administered such a dose, made so strong that I would not have dared to taste it myself, afterwards told me that it was the most refreshing and *cooling* drink he had ever taken. A London surgeon to the police told me that he had treated a hundred and fifty cases of delirium tremens with this remedy *alone*, and had not lost one. The use of *chloral* in these cases is criminal, and many a death-certificate of “delirium tremens” ought to be “heart-failure from chloral-poisoning.” Mucilaginous teas and drinks made from gelatin, isinglass, Irish moss, and flaxseed are very soothing to any inflammation within the digestive tract. Green vegetables are necessary to cure as well as to prevent scurvy.

An old practitioner, who had spent his early professional life in the country, told me that when he first commenced practising he used all the ordinary remedies in typhoid fever without any satisfactory results, until the introduction of turpentine by the late Prof. George B. Wood. In it he soon discovered a useful ally, not so much in the drug *per se*, but because con-

venience and time compelled him to use a thick flour-gruel as a vehicle, and the patients were nourished sufficiently to live through the attack.

In the science and art of preparing sick-diet there is a most lamentable lack of knowledge, especially among physicians. They know the preparations by name, but not by nature, and the only way to learn the latter is to don the apron and take a practical course from a practical and scientific cook. Such a course was inaugurated last winter in this city and in Boston with a very satisfactory result. The prospect for this season in this city is that the course will be very well attended. It is the only way to learn. I could read you receipts by the score, but it would be as useless as reading off that many medical formulæ.

A CASE OF AMPUTATION OF THE BREAST, WITH REMARKS.

*Read before the Philadelphia County Medical Society,
September 12, 1883.*

BY HENRY LEAMAN, M.D.

MRS. J. J. W., æt. 48, married twenty-nine years, is the mother of eight children still living, and has been the subject of ten severe miscarriages. She presented herself at my office on the 1st of September, 1882, complaining of a tumor in her breast, which she had noticed for the first time three months previous. At that time a small pimple upon the surface of the skin served to call her attention to the swelling that lay beneath in the substance of her breast. Examination showed a tender enlargement, the size of an English walnut, situated deeply in the inner lower quarter of the left breast. She stated that during the past week she had experienced for the first time frequent sharp, retracting pains shooting through the nipple. Menstruation had ceased with her six years previous, without giving rise to any trouble. She now had no cachexia, and was apparently in her usual health.

On the 18th of the same month she called again; the growth had not perceptibly increased, but she spoke of having pain in her breast-bone. Amputation of the breast was recommended. The effect of this advice was to send her upon a blind pilgrimage through the desert of therapeutics. Now electricity, now pow-wow-ing, now homœopathy,—each in its turn was

tried, with results equally gratifying to the patient.

The ignis-fatuus which I had lighted brought her again to me on the 23d of April, 1883. The tumor then was of an oval shape, and about four inches in length. From its inner anterior surface were extending two cornua, slightly ulcerated, about three-fourths of an inch in length. The skin over the tumor was deeply congested, red, and inflamed, as was also the skin for several inches around. The tumor in front rested upon the cartilages of the rib, but was movable. The glands in the axilla were slightly involved. With the assistance of Drs. Hatfield, Brubaker, Welch, and R. Leaman, the breast was removed under the spray, on April 26, 1883, and Lister's dressing applied.

One nodule of hardness was removed from the axilla. At the sternal end the cut surfaces could not be approximated within two inches, owing to the necessary ablation of tissue.

On May 8, the posterior three-fourths of the incision had entirely healed and were healthy. The anterior one-fourth was perfectly healthy and granulating rapidly. All sutures and the remaining ligatures were removed.

On and after May 10, the wound was dressed with iodoform, cosmoline, and salicylated cotton, under which treatment the wound rapidly healed. Dr. Brubaker made a histological study of the growth, and pronounced it carcinoma.

As soon as the cicatrix was complete, neuralgic pains began to be felt in the left arm, right leg, and body. At first the cicatrix remained perfectly healthy in appearance. Subsequently, however, a nodule appeared in the lower part of the neck behind the left sterno-clavicular articulation. Next, the left axilla, the posterior and healthy part of the cicatrix, both began to show hardening. At present there is a chain of nodules along the whole cicatrix,—one large and painful is felt over the cartilage of the third rib on the left side. The left axilla is but one hard pyramid. The left hand and arm are swollen. A pain of a lancinating, burning character is referred to the left scapula, arm, and axilla, occasionally shooting in the course of the incision.

The apparent freedom from involvement of the axillary glands at the time of the operation, and the rapid development of

the disease after the healing of the cicatrix, would seem to point to the idea that the original tumor was but a local nidus for a constitutional trouble, and that this having been destroyed, a general efflorescence of the disease ensued. A kindred idea is found in the popular belief that a manifestation of phthisis may follow the operation for the cure of anal fistula. The observations on the change of life in women would seem also to bear upon the same point.

Dr. Brubaker's Analysis of the Tumor.

—"Upon section the tumor is firm and hard, and presents a white, glistening surface, from which can be scraped a small quantity of fluid matter. Under the microscope the connective-tissue stroma is seen to be abundantly developed; in its meshes are developed epithelial cells, some of which have undergone degeneration. In some situations the cells are arranged in a linear manner, whilst in others they form groups or nests."

REMARKS ON THE CHICAGO BEEF WIRE SKEWER.

*Read before the Philadelphia County Medical Society,
September 12, 1883,*

BY W. R. D. BLACKWOOD, M.D.

THE supply of good, wholesome meat to a large city is a problem involving many points of great importance. Many cattle are slaughtered within a few hours after reaching the abattoirs; before the feverishness and excitement resulting from a long railroad-journey have abated, and the meat under the circumstances is not nearly so good or suitable for food as it would be even in healthy and prime animals, were it killed after a due time of rest. For a short time past beef slaughtered in Chicago and brought here in refrigerator cars has attracted the attention of those able to judge the article according to its merits, and for quality it is pronounced fully equal to any heretofore put on the market, and far ahead of the great bulk previously sold in the city, so far as a wholesome, sound, and moderate-priced beef is concerned. The animals are selected from approved droves, and well fed, watered, and housed for a definite and proper time before killing, and the product, therefore, is not only in its appearance perfect, but in the vital point of fitness for wholesome, nutritious, and palatable food it is unrivalled.

Some weeks ago a sensational attack was made on this variety of beef in the interest of a clique of butchers in this city, who, knowing the value of the Chicago article, were afraid of the effect on their business when it became better known to the public, and the silliest pretext, among others, advanced, was a supposed danger to consumers from the novel skewers employed to fasten the labels on the hind and fore-quarters, these being of barbed wire such as I exhibit to you to-night. It was predicted that an epidemic of harpooned tongues, tonsils, and pharynges would ensue from swallowing unawares by consumers the numerous wire skewers concealed in the meat, and I am informed that for a time a serious falling off in sales actually resulted from fear on this point. You will readily see that any one who would try to gulp down a morsel of meat large enough to hide this fastener must at the same time be in a famishing condition, have the appetite of a tiger, and need lessons in table etiquette, to put it mildly.

The labels which are attached—one to each quarter only—are removed by the butcher before cutting up the meat, and could not, even if allowed to remain, fail to attract attention of both cook and eater. Mr. Bradley, of the Great Western Market, is the largest dealer in this city of this excellent beef, and he has kindly supplied me with samples of the barbs. The claims which he makes for the particular beef under consideration are worthy of notice, as his experience in business for some years past is unequalled in this city, and the enormous quantity which he distributes to a large section of surrounding country fully justifies the high value he places upon it. I am glad to confirm what he says, from personal experience in my family. The meat is simply delicious, and excels anything we have previously had from the best butchers of the city.

TWO CASES OF COMPOUND AND COMMUNUTED FRACTURE OF THE SKULL.

BY C. W. DE LANNOY, M.D.,

Chester, Pennsylvania.

IN connection with the explosion of Jackson's pyrotechnic works in March of 1882, there occurred, among the many serious injuries inflicted by various projectiles, a series of fractures of the skull, of

which two furnish interesting data concerning the nature of these accidents and the results of treatment.

As an explosion was not anticipated, and the building was in the act of burning, the ordinary curiosity of a street crowd kept all faces directed towards the scene of action; in consequence of this, all wounds inflicted by missiles were situated upon the ventral or anterior surfaces of the body. Both fractures of the skull to which I here allude were situated above the eminences of the frontal bone, the ages of the patients, both males, being respectively nineteen and twenty-eight.

Case I. was first seen three days after the accident. Some good Samaritan had carefully closed the lips of a three-inch scalp-wound, extending obliquely across the left frontal region above the eminence. At the time when seen by myself and a colleague, who had the case in charge, the boy presented the appearance and conditions peculiar to one suffering from compression of the brain. Removing the stitches and thus releasing an abundant collection of coagulated blood and pus from beneath the scalp, fragments (*b*, Fig. 1) were taken away, all of which repre-

FIG. 1.

PORTIONS OF THREE TABLES, OS FRONTIS OF LEFT SIDE. *a*, internal table and portion of middle table; *b*, external table and portion of middle table.

sent what was lost of the external table, about one-half the thickness of the middle table clinging to their under surfaces. The

internal table (Fig. 1, *a*) was completely detached and turned over, so as to present its concave cerebral surface at the bottom of the wound. This plate was removed in three pieces, and the pulse of the patient rose from 30 to 60 almost instantly. With proper care as to local and constitutional treatment, the case steadily progressed to a favorable issue.

Case II. was that of a strong, wiry Irishman, who filled the office of fireman at the time of the explosion. On the third day after the accident, which was the time chosen for the operation, he was not suffering from a single symptom of either concussion or compression of the brain. Fragments of bone removed from his head (Fig. 2, *a* and *b*) were very

FIG. 2.

PORTIONS OF THREE TABLES, OS FRONTIS OF RIGHT SIDE. *a*, cerebral surface of internal table; *b*, fractured external and middle tables.

much comminuted and pushed down into the substance of the cerebrum, which we found considerably lacerated and softened; it may, in fact, be fairly stated that at least a teaspoonful of brain-matter came away with the many fragments of bone removed. Recovery was steady and progressive, with but few drawbacks, all due to imprudence of some kind on the part of the patient.

While I know but little concerning the details of these cases, yet from the adjoining histories and illustrations several interesting subjects for argument may be chosen.

In the first place, both fractures were compound and comminuted, and resulted from a concentrated blow, of which the force had been largely spent in producing the local lesion. In both, injury to the brain was limited to parts immediately beneath the seat of fracture; particularly was this true of No. 2, who from the beginning presented no symptoms of either concussion or compression. Case No. 1, through the ignorance of his first attendant, was, I

believe, reduced to the condition in which we found him, by the retention of intracranial blood-clots and discharges, and therefore incurred far greater risks of secondary intracranial inflammation than were to be anticipated for his fellow-sufferer.

Another important and noticeable feature is the difference in proportions as to the size of the pieces removed from the external and internal tables. In the case of No. 1 there was considerable shelving off of the internal table, while in No. 2 the external is relatively larger than the internal. Facts, fortunately, confirm theory in affording a reason for these differences. No. 2, who was acting as fireman close by the source of explosion, must have received the more powerful blow, one which, by its intense violence, might be said to have cut through the entire thickness of the calvarium without any lateral distribution of force, and the depth of injury sustained was greater and entirely out of proportion to its extent. On the other hand, No. 1 was standing at a distance, as a spectator only, and received the blow from a projectile which by the time it reached him had lost much of its original impetus. Now, all are familiar with the different results which attend the contact of projectiles with hard substances, when propelled from long or short distances. In the former case there is always more splintering, particularly at the point where the projectile obtains exit from the body it has come in contact with. In the latter case we meet with an aperture uniform in character throughout the entire thickness of the body struck by the missile.

It might prove of further interest to state that, although No. 2 lost a not inconsiderable amount of brain-cortex, both as the result of immediate injury and during the subsequent period of discharging, yet no mental or intellectual disturbance has been the result. For this I have my own evidence and that of his relatives. What bearing this fact may have upon the theory of the unilateral functions of the cerebrum I am not prepared to decide. It will be remembered, however, that experience has taught us that aphasia is at least in the large majority of cases associated with *right* hemiplegia, which, of course, means a hemorrhage affecting the *left* third frontal convolution,—aphasia rarely occurring when the hemorrhage is upon the opposite side of the brain. From a similar association

of the left cerebral hemisphere alone, with the function of intellection, injury of the right side (as in Case No. 2) would occasion no mental disturbance. The argument, however, is purely theoretical, and needs the support of an experience with brain-injuries which I have not the good fortune to possess.

Before leaving the discussion, I would refer to the use of plates as substitutes for the bone lost in comminuted fractures of the cranium. Judging from the results obtained in these cases, I regard them as totally unnecessary, and should deprecate the use of artificial means of protection in cases for which nature does so much to replace the bone lost by accident. The attempts at repair, in both of these injuries, have resulted in the formation of a tough fibro-cartilaginous plate, which appears to afford the necessary protection to the delicate organs beneath, and, beyond wearing an external pad of hard rubber or other appropriate material under circumstances that might be thought to render such additional protection desirable, it would seem unnecessary, to say the least, to attempt further interference with nature's *modus operandi*.

REPORT ON THE PROGRESS OF OTOLOGY.

BY CHARLES H. BURNETT, M.D.

PHYSIOLOGY OF THE COCHLEA IN VERTEBRATES.

DR. B. BAGINSKY,* of Berlin, has recently laid before the Academy of Sciences of Berlin the results of a series of investigations on the cochlea of dogs. After alluding to the investigations in this direction by Helmholtz, Hensen, and J. Ranke, he deplores the fact that there have been no experimental researches which have resulted in any fixed conclusions regarding the cochlea of vertebrates, until the recent observations of H. Munk, who has shown that dogs in which the lower wall of the cochlea, near the round window, had been broken away, after remaining deaf for a period of fourteen days, again heard, though very imperfectly, and their perception of sound was limited to lower notes and noises. With this fact in view, Dr. Baginsky has performed a series of experiments on dogs, in the Veterinary School of Berlin, in order to find out

* June 14, 1883.

whether, and how far, the various parts of the cochlea, especially those portions on the *membrana basilaris*, are functionally dissimilar.

His plan of investigation has been, after opening the *bullæ ossea*, to destroy entirely one cochlea, so as to render the dog totally deaf on this side and thus exclude one ear from the observations. In the other cochlea various parts have been destroyed, either by piercing it or by chipping off portions of it.

After this treatment, the dogs have been tested for long periods as to their ability to hear notes on organ-pipes, arranged for the purpose with the greatest care, and ranging from C' to c'''' , the lowest and highest of which were open pipes. Finally, in the course of from three to ten weeks, when no further changes in the hearing could be detected, the animals were killed and the labyrinth removed. Then an uninterrupted series of sections were made, parallel to one another, in the direction from the base to the tip of the cochlea, and examined under the microscope.

The exclusion of one ear was very difficult, as either death resulted from the attempt to destroy the labyrinth, or phenomena of altered equilibrium were manifested, with partially-retained hearing.

But the slighter wounding on the opposite cochlea, when not productive of death or oscillations of the head, often produced, by the resultant inflammation, permanent deafness. However, even with this good result, many of the dogs, by reason of their inattention, etc., did not furnish reliable results in testing their hearing. In a large number of experiments, only a few proved of any value in the microscopic examinations. It was especially desirable to show finally, by the microscope, that pathological changes in one of the cochleæ had occurred throughout the organ, while in the other they had occurred only in the wounded portion. In the latter connection it was of great value to see that, with the finer changes in the fibres of the auditory nerve, grosser changes were also detected in the cells of the *ganglion spirale* and of the *intumescencia gangliiformis Scarpæ*.

Dogs made completely deaf in one ear, and partially so in the other ear, by boring into the point of the cochlea, were, in the course of a few days, aroused only by the report of a pistol; towards the end of the first week they reacted distinctly to the

note c'''' , and in some cases to the note c''' . In the course of the second week the dogs heard c'''' and c''' ; only rarely as low as c'' . Reactions to sounds thus established became soon distincter, but did not descend the scale. As long thereafter as the animals lived, they did not hear notes as low as c''' or c'' .

Anatomical investigation of the cochlea the point of which had been broken showed that the upper turn and the greater part of the middle turn were filled with fibrous cicatricial tissue, with destruction of the normal contents: the lower remnant of the whorls of the cochlea and the rest of the labyrinth were entirely normal. Upon the other side—i.e., where the hearing was destroyed—the cochlea was either entirely or nearly filled with cicatricial tissue. In the latter case, if the original soft parts were at all recognizable, it was seen that all or very nearly all the nerve-fibres and ganglion-cells were degenerated.

Dogs in which one ear had been made entirely deaf and which had been injured in the other ear by breaking off a small portion of the promontory at the base of the cochlea, manifested often temporary deafness in the latter ear. Very often it was found in these cases that not the entire cochlea but only the lowest turn was filled with cicatricial tissue, either in both *scalæ* or in the entire *scala vestibuli* and in part of the *scala tympani*, and also that the *membrana basilaris* was at these points destroyed. Sometimes in these instances fibrous constrictions in the trunk of the acoustic nerve were detected.

In more successful cases, in the course of a few days the dogs would move upon the discharge of a pistol, and later they would hear musical notes, first only slightly, then gradually more decidedly.

In a certain number of dogs, in respect to the beginning and the extent of the reaction, no difference was detected between high and low notes. A second set of dogs, in fact, a large class, began to react at once, both to high and low notes, but the reactions to low notes were at first distinctly stronger than those to high notes. Finally, in a third and smaller class the reactions were at first and for a longer time only in connection with low notes, the three or four lowest octaves; and at last, in the course of one or two weeks, reactions occurred in connection with higher notes. In conclusion, all these dogs appeared to

hear these high and low notes in a normal way.

In the ear which had been made entirely deaf, the cochlea was found altered in a way similar to that already described for injured parts of the opposite cochlea. In the latter ear, the small defect in the base of the cochlea, where the bone had been cut away, had been closed by a membrane, and in a small portion of the lowest whorl of the cochlea, which is nearest the round window, the entire *scala tympani*, or a part of it, and now and then a part of the *scala vestibuli*, were filled with fibrous tissue. In such cases, the *lamina spiralis membranacea* was often embedded in the fibrous tissue and destroyed. Otherwise, all other parts were normal, excepting that, at most, sometimes here and there in the cochlea a few nerve-fibres and ganglion-cells were apparently degenerated.

The beginning deafness in the less affected ear, the return of hearing, and the manner of its increase in all the experiments are explained by the loss of the fluid contents of the cochlea, and by the inflammation extending from the point of irritation throughout the membranous parts of the cochlea. The return of hearing is accounted for by the fact that after a slight laceration the wound closes, and the inflammation undergoes retrograde metamorphosis to a certain extent.

It was not supposable that after healing had occurred abnormal tensions temporarily existed in the basilar membrane, and the post-mortem examinations gave no support to the view that local contractions of this same membrane existed. It is claimed by Baginsky that the above experiments show that *the point or cupola of the cochlea contains the parts of the nerve concerned in the perception of low notes, while the base of the cochlea, near the round window and the promontory, contains the portions of the nerve concerned in hearing high notes.*

Upon this supposition many points in relation to *sound-conduction*, as well as *sound-perception*, may be made clearer, and your reporter draws the following practical deductions:

It must be borne in mind, first, that the sounds most important for the human ear to hear are those of the human voice, and, second, that these sounds are among the high rather than among the low notes in the musical scale. We also learn by the researches of the experimental physiologist

that the parts of the internal ear which are best adapted to the perception of high notes are probably not only in the cochlea, but in that part of it nearest the promontory and the round window,—*i.e.*, nearest the tympanic cavity,—since these two parts of the cochlea abut upon the tympanic cavity. It is seen, then, by this anatomical arrangement and topographical distribution of the terminal nerves in the cochlea already described that those parts of the auditory nerve most important to have easily thrown into vibration, and, in fact, those most likely to be called into action by the sounds of the human voice, are placed where sound-waves would be most likely to reach them directly. For it is a physical fact that when sound falls on the *membrana tympani* some of it passes directly through the membrane, and across the tympanic cavity, and strikes upon the membrane of the round window and upon the promontory. Sound taking such a course would thus act almost directly upon the terminal nerve-fibres in the cochlea, underlying these two points, without pursuing the more roundabout way through the oscillations of the chain of auditory ossicles. By pursuing the latter course a sound-wave would impress the nerve-fibres in the cupola of the cochlea, which seem adapted to the perception of low notes, before it reached the round window. After passing the cupola, at the end of the vestibular canal, it would enter the tympanic canal of the cochlea, but would not impinge upon the nerves concerned in the perception of high notes (the important ones in our present consideration) until it reached the round window at the end of the tympanic canal of the cochlea. Hence it seems probable that high notes can be and are very largely heard directly, without being obliged to traverse the longer course through the oscillating chain of bones.

Another proof that the nerves lying near the promontory and round window are concerned in the perception of high notes is given by the experiments of C. J. Blake* with König's rods. It was here shown that when the *membrana tympani* was perforated, and the high note of a König rod thus more readily permitted to fall directly on the promontory and round window, not only very high notes could be heard, but considerably higher than when the mem-

* Transactions American Otological Society, 1872.

brana tympani was imperforate. It also showed that the important ability to hear high notes was retained, notwithstanding the loss of integrity in the drum-membrane.

If, however, the passage of sound-waves to the tympanic cavity, or to the membrane of the round window and promontory, is impeded, as in disease, then, of course, the nerve-filaments in the cochlea near these points cannot be reached easily.

Thus, in coryza, the first impairment of hearing is in connection with the higher and delicate tones of the human voice; because in such instances the nerve-fibres lying nearest the promontory and round window cannot be reached by sound-waves, on account of the swelling of the tympanic mucous membrane near these parts.

THE SIGNIFICANCE OF THE TRANSMISSION OF SOUND TO THE EAR THROUGH THE TISSUES IN AURAL DISEASE.

Dr. Samuel Sexton, of New York City, in a paper on the above topic, read before the American Otological Society at the annual meeting, July 17, 1883, draws the following conclusions:

1. When the vibrating tuning-fork, placed on the teeth or vertex, is better heard through the tissues on one side, it simply indicates that the better ear excludes wholly or in part such (tissue) transmission; but it does not prove that the auditory nerve in either is affected. (Of course, if the nerve of audition be gravely affected, sound will not be heard by any method of conduction.)

2. If the conductive mechanism is absent or greatly damaged in one ear, while the other remains more or less normal, aerial transmission will be found to be ineffectual in the diseased ear, while the tuning-fork, allowed to vibrate as before, will therefore be best heard in the diseased ear, while its vibrations will be almost entirely excluded from the healthy ear.

3. In labyrinthine disease pure and simple, the middle ear being normal, the tuning-fork would be best heard by aerial conduction; because bone conduction would be excluded. (In those extreme cases where destructive disease of the nerve has taken place, impulses of sound may be appreciated irrespective of either the transmitting or labyrinthine structures: thus, the deaf-mute is conscious of the sound of thunder, artillery, drums, stamping of feet on the floor, and the like.)

4. If the above deductions be true, we

may conclude that the tuning-fork is of but little if any value in the differentiation of aural disease; and the same applies to König's rods.

In this connection your reporter would submit the following original reflections upon the diagnostic value of the tuning-fork, and upon the erroneous deductions made by its use regarding the nature of aural disease, especially in reference to so-called cochlear inflammation, supposed disease of the auditory nerve, and altered perception of sound in syphilitic disease of the ear.

The phenomena observed when a vibrating tuning-fork is placed upon the vertex, glabella, or teeth, either in an individual with or without normal ear or ears, have certainly been misunderstood. This has led to a misapplication of them in diagnosis, and to very false conclusions.

The chief error lies in considering the results obtained by its use as data for estimating the *perceptive* power of the nerves, rather than the *conducting* power of the auditory apparatus in the external and middle ear.

Hence phenomena in the manner of hearing the tuning-fork through the tissues have been attributed to alterations in the nerves, as in so-called "cochlitis," instead of to changes in the mucous membrane of the drum-cavity and in that covering the ossicula. The slightest changes in conducting power, which ensue upon the least change in the mucous membrane of the drum-cavity and its contents, or in the auditory canal, instantly alter greatly the way in which the tuning-fork is heard; whereas changes analogous in kind or extent, in the auditory nerve, would render it inactive as a percipient organ.

Thus the diagnostician in his eagerness has jumped over, so to speak, the nearer and plainer explanation of phenomena in the hearing of the tuning-fork, offered him in the changes in the drum-cavity or its contents, and has sought for an explanation of the morbid phenomena of audition in the more remote and less understood internal ear.

Thus it has come about that an endeavor has been made to establish the existence of a "syphilitic cochlitis,"* the so-called acoustic phenomena in which may be accounted for much more easily by the sup-

* Roosa, First Congress International Otol. Society, 1876.

position of altered conduction by reason of changes in the mucous membrane, so well known to occur in syphilis, than by the difficult and entirely untenable view that the changes in audition are due to alteration in the nerve and hence are phenomena of altered perception. This endeavor to remove the diagnosis from the nearer and more probable ground to a remoter and less known one has been not only unnecessary, but misleading; unnecessary, because the experiments of Helmholtz, Politzer, Buck, Hensen, C. H. Burnett, and McKendrick upon the mechanism of the ossicles and their relation to audition have been demonstrable *ad oculos*, and have made clear the phenomena of conduction of sound and how it may be interfered with; whereas we know positively nothing about the mechanism of perception of sound in the labyrinth.

Hence the endeavor to refer phenomena most probably occurring in the tympanic cavity and attributable to altered conduction, to a part of the ear unknown, excepting that it is concerned in all probability with perception, is unscientific, and misleading to younger minds.

The fact that sudden deafness in a syphilitic patient has been cured by an anti-syphilitic remedy is by no means a proof that the disease lay in the cochlea and was due to a "cochlitis." It would be just as much a proof, perhaps more, that the disease lay in the mucous membrane of the drum-cavity or of its contents, and, by interfering with sound-conduction, had caused deafness, and that the latter had been removed by the anti-syphilitic action of the drug upon the mucous membrane. Furthermore, if by "cochlitis" an inflammation in nerve-tissue is implied, it is by no means clear, on any ground, that an easy removal of the inflammation could be effected by any remedy, or, if the disease were removed, that the hearing would return either so quickly or so completely as in the cases of so-called "cochlitis" recorded by the writer alluded to.

REMARKABLE LONGEVITY OF A PHYSICIAN.—The death is announced of Dr. Jachimowicz, of Jarosinka, in the government of Kiew, Russia, at the ripe age of one hundred and six. It is said of him that he was able to superintend his extensive and successful practice till near the end of his life.—*Medical Press*.

TRANSLATIONS.

INFLAMMATORY FUNGOID NEOPLASM OF THE SKIN.—Dr. R. Naether reports the following remarkable case from Prof. Wagner's clinic in Leipsic. The patient was a man, aged 40 years, without any hereditary predisposition or syphilitic history. In July, 1881, after being exposed to the wet, he suffered from gastric disturbance, lasting only for a few days, but in the end of August of the same year an eruption broke out on his entire body, with the exception of the face, in red, burning, itching, and elevated spots, about the size of a dollar, which a month later extended to the face. This condition remained about stationary until September, 1882, when the spots increased greatly in size and secreted a rapidly-decomposing fluid. The growths then increased to such an extent as entirely to destroy sight and all resemblance of the face to that of a human being, the only place where the skin appeared at all normal being at the tip of the nose. A few growths were also found scattered over the body. Death occurred from prostration on November 28. This disease is regarded by Dr. Naether as *granuloma sarcomatodes cutaneum*.—*Deutsches Archiv für Klin. Med.*, July 31, 1883.

GANGRENE OF THE PENIS AS A CONSEQUENCE OF ACUTE GONORRHOEA.—Jeszczynski reports the case of a robust countryman, 23 years of age, who was seen by him seven days after infection: the discharge and swelling of the penis had then lasted four days. The glans was completely covered by the swollen prepuce; there was a profuse greenish discharge and sharp pain at the root of the penis, which was greatly swollen and of a greenish-brown color. Incisions were made in both sides of the penis, extending along its entire length, and a large quantity of fetid pus evacuated. On the next day several vesicles had formed on the external skin surface, and a circular line of demarcation was commencing to form at the inner end of the incisions, and three days later the entire gangrenous skin separated; no fever was present. Healing took place by granulation under iodoform dressings, and was complete in about five weeks, leaving two broad scars on the upper surface of the organ.—*Centralblatt für Chirurgie*, August 4, 1883.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, OCTOBER 6, 1883.

EDITORIAL.

ANNOUNCEMENT.

WITH the last number, and the close of the thirteenth volume, Prof. H. C. Wood resigned the duties and responsibilities of the position of chief editor of the *TIMES*,—duties which he had so long and so ably discharged, and responsibilities with which he had become identified. On account of increasing engagements, Dr. Wood has been reluctantly compelled to take this step, which he had contemplated for some months, and which he felt that he might safely do now that the prosperity of the *TIMES* (and, in truth, mainly through his able and vigorous management) appears firmly established. As will be noticed in the present number, he will still continue his welcome contributions to its pages.

This being the first issue of the volume, we have commenced a series of reports upon progress in the several departments of medicine, which will henceforth appear regularly throughout the year, arrangements having been made for these articles with gentlemen possessing special qualifications for the duties which they have undertaken. It is believed that this new departure will be found acceptable to our readers. The subjects and reporters are as follows:

On Nervous Diseases, also Therapeutics and Materia Medica, HORATIO C. WOOD, M.D., Professor of Materia Medica, Pharmacy, and General Therapeutics, and Clinical Professor of Diseases of the Nervous System, in the University of Pennsylvania, etc.
On Obstetrics and Gynæcology, THEOPHILUS PARVIN, M.D., LL.D., Professor of Obstetrics and Gynæcology in the Jefferson Medical College of Philadelphia, etc.
On Anatomy and Surgery, J. EWING MEARS, M.D., Professor of Anatomy and Surgery

in the Pennsylvania College of Dental Surgery; Demonstrator of Surgery in the Jefferson Medical College, etc.

On Syphilis and Genito-Urinary Diseases, J. WILLIAM WHITE, M.D., Lecturer on Operative and Genito-Urinary Surgery, with Venereal Diseases, in the University of Pennsylvania, etc.

On General Pathology and Clinical Medicine, JAMES C. WILSON, M.D., Physician to the Philadelphia Hospital and to the Hospital of the Jefferson Medical College, etc.

On Diseases of the Throat and Nose, CARL SEILER, M.D., Lecturer on Laryngology in the University of Pennsylvania, etc.

On Medical Applications of Electricity, W. R. D. BLACKWOOD, M.D., Physician to St. Mary's Hospital; Consultant on Nervous Diseases, and Electrician to the Presbyterian Hospital, Philadelphia, etc.

On Diseases of the Skin, ARTHUR VAN HARTLINGEN, M.D., Professor of Diseases of the Skin in the Philadelphia Polyclinic, etc.

On Diseases of the Ear, CHARLES H. BURNETT, M.D., Professor of Diseases of the Ear in the Philadelphia Polyclinic; Aural Surgeon to the Presbyterian Hospital, etc.

On Diseases of the Eye, ALBERT G. HEYL, M.D., Ophthalmic Surgeon to the Episcopal Hospital, etc.

On Morbid Anatomy and Pathology, MORRIS LONGSTRETH, M.D., Lecturer on Pathological Anatomy in the Jefferson Medical College; Pathologist and Curator to the Pennsylvania Hospital, etc.

On Physiology, ROBERT MEADE SMITH, M.D., Demonstrator of Physiology at the University of Pennsylvania, etc.

On Medical Chemistry, WM. H. GREENE, M.D., Professor of Chemistry in the Philadelphia High School; formerly Demonstrator of Chemistry at the University of Pennsylvania, etc.

On Hygiene, Toxicology, and Medical Jurisprudence, HENRY LEFFMANN, M.D., Professor of Clinical Chemistry and Hygiene in the Philadelphia Polyclinic.

With this exception, the *TIMES*, under its present management, will continue the features that our readers are familiar with,—pursuing the same outspoken and independent course which has characterized it in the past, upon subjects of general pro-

professional interest. True to the principles expressed in the Code of Ethics of the American Medical Association, and a consistent advocate of scientific rationalism in medicine, it will continue to advocate higher medical education, and to lend its voice and influence to every measure calculated to raise the standard of medical practice.

"CROWNER'S 'QUEST LAW."

IN the discussion of the qualifications of a candidate for coroner, we think that it must be conceded that the examination of a corpse in order to determine the mode of death can properly be performed only by a person fitted by training and experience for the work; in other words, he must be a physician. Any one not possessing such training and experience is disqualified from forming a sound and reliable judgment upon the evidence presented. The medical examiner system of Massachusetts has demonstrated the fact that the requirements of both science and law are better satisfied by having the duties formerly performed by a coroner intrusted to a purely medical commission, since questions constantly arise, both at the inquest and in court, which can only be answered by physicians. The only excuse for the continuance of that mediæval functionary, the coroner, therefore, will be that he himself is a physician. The profession in this city made a special effort some years ago to have this truth acknowledged by our masters the politicians, and for several successive elections it has been accepted as the principle in making nominations. One of the contending parties has recently seen fit to break this rule and to nominate a candidate who is not a physician; the other very wisely nominated a gentleman of high professional standing who possesses all the qualifications required for the office. Those physicians of Philadelphia who are in favor of supporting principle rather than party will have an oppor-

tunity afforded them this fall of re-asserting the principle they have declared, that the coroner must be a medical man. It is not very complimentary to the profession to be told that the political coroner can spare out of his fees enough money to pay two physicians to work under him. It would be much better, if there is income enough to share among three, that the third also should be a medical man, and thus have medical examiners entirely independent of any simply political influence. The coroner has relations with the medical profession, and claims that he has power to reprimand physicians and fine or commit them for contempt (for under such circumstances their true feelings sometimes may be inadvertently expressed, even though it would be better policy to conceal them): on account, therefore, also of these professional relations, should this functionary (if not really *functus officio*) be not merely a physician, but also one whose standing and attainments will command the respect and support of the profession.

CLINICAL INSTRUCTION AT THE PENNSYLVANIA HOSPITAL.

REFERENCE to the early history of the Pennsylvania Hospital shows that when the project of starting the hospital was first broached in this city the fatal objection was made that means were wanting to pay the physicians for their attendance upon the patients, thus recognizing, at that date, the principle of equity that no one has the right to enjoy the labor and time of another without rendering to him an equivalent in return. When informed of this difficulty, certain physicians, out of pure charity, volunteered their services to attend the poor in the wards who were unable to pay. Subsequently the physicians agreed also to contribute their fees received from students in attendance upon the practice of the house, towards forming a library. The library grew, and the fees

increased even more rapidly, so that a surplus of some fifteen thousand dollars had gradually accumulated a few years since; which, however, was not returned to the lawful owners, the medical staff, as it should have been, but was "loaned" to the hospital-funds. At a recent meeting of the managers of the hospital a resolution was adopted, the object of which is to create a revenue to the hospital by requiring physicians to give clinical lectures, and by charging students five dollars each for admission to them. This will have the effect of reducing the size of the classes to such a point that it would be absurd and inconsistent with self-respect for such eminent practitioners to waste time in lecturing before them. We hope that the managers will rescind this act, as it practically closes the doors of this old and venerated institution to clinical teaching, and reduces the gentlemen of the medical staff, in the eyes of the public, to a menial position, if not to practical slavery.

LEADING ARTICLES.

THE SOUTHWEST AS A HEALTH-RESORT.

EACH year, as the winter threatens, in the Northern United States an exodus begins of those who are already stricken with or who fear consumption, and flows steadily towards Florida. That State certainly offers to the invalid great natural beauty, balmy airs, and moderately good hotels; but its distressing crowding, its abundant malaria, and its moist air, favoring, in many cases, pulmonic softening, are very serious obstacles to recovery of health.

As is well known, there runs almost through the United States, from San Antonio, Texas, northward, a wide strip of country whose air is extraordinarily dry. Less convenient of access, mostly unsupplied with hotels and the resources of civilization, this region has nevertheless begun to endanger the supremacy of Florida as a winter health-resort for consumptives.

To our thinking, for most cases of phthisis its superiority over Florida is unquestionable. The intense dryness of the air

renders the latter more stimulating to the general system. Dry heat is borne much more easily than moist heat, dry cold than moist cold, and at a moderate temperature the dryness seems to brace up nerve and muscle. Further, experience shows that pulmonic breaking-down occurs much more slowly under the desiccating influence of a Texan desert than under that of a soft sea-air.

The great natural beauties of Colorado, and the circumstance that railroads first went into this part of the dry belt, have led to its development as a sanitarium. The height of these health-resorts above the sea tends, however, to the production of hemorrhage, by necessitating more work on the part of the lungs, whilst the intense winter cold enforces during many months a chiefly in-door life.

Without occupying more space and time with discussion, enough has been said to show why the climate and circumstances of the southern portions of this dry belt should be carefully studied by physicians, and why there is a rapidly-increasing pilgrimage each winter to Texas.

In Texas itself the opinion among both the laity and the profession is wide-spread that the consumptive should spend the whole year, and not a part of it, in the State if he hopes for arrest of his disease. This opinion seems well founded. Mere warmth of climate is chiefly valuable to the consumptive because it allows free out-door existence and lessens the tendency to catarrhal attacks. Great dryness of air seems to have a more direct curative influence, and really to arrest or prevent pulmonic softening; and when warmth and dryness are associated the conditions are most favorable.

The difference between the air of the far Southwest and that of the East is at least as great in summer as in winter. The United States Army Regulations require that a horse shall be given five gallons of water; but in Texas during the summer twenty gallons are required, even though no work be done. A man when marching will drink two to four gallons of water in the twenty-four hours. I have myself drunk one-half gallon in twenty minutes after a seven hours' march without water. A very noticeable thing under these circumstances is that, though such enormous draughts of water are taken, scarcely any urine is passed,—certainly not one-half of

the amount ordinarily voided in the same period at home. The escape of water by insensible perspiration is enormous; and it is a question well worth practical study as to the possibility of curing early Bright's disease by thus bringing to a minimum the work required of the kidneys.

The consumptive who hopes to find life in this dry region ought to seek it all the year round.

In regard to the winter climate of Texas we do not mean to say much. It is an axiom that out-door life is the life for the man with weak lungs; and a guide and tent are here, as in Florida, worth more than medicine and fine hotels in the beginning of the disease. If the patient have ample means, an ambulance, a pair of mules, a guide, and a Sibley tent make life in the winter months of Texas not only possible but pleasurable, and, if the traveller be anything of a sportsman, enjoyment and a very important addition to the *menu* may be had, provided care is taken to go into a game region. A large part of the State is no better than a desert, with little or nothing in it; but, what with four species of quail and numerous waterfowl in the more cultivated parts, antelope, deer, and turkeys, and the Mexican and Messina quail, in the wilder regions, it is easy to arrange a trip so as during the winter months to find game continually in abundance.

An advantage of this mode of life in Texas is, that, if meats be supplied by the gun, by means of California canned goods a very excellent table can be spread at a comparatively moderate cost. During a recent outing, buying of the United States commissariat, our mess-bills for a party of four were ten dollars a week apiece. In this bill were included whiskey, which some of the party declined, and for all an abundance of California claret (a good, honest wine, which may be purchased in San Antonio for one dollar a gallon), and also the monthly wages (thirty-six dollars and food) of a cook.

The tent must be provided with a stove; otherwise the sudden northers of Texas would be unendurable. The temperature at any time of a day may be that of a Northern June, when across the prairie appears a sharply-defined dark cloud, with a column under it, marching steadily and rapidly forward. The column is a raging mass of wind and hail and snow, and pro-

tection from it is absolutely necessary. An immediate halt and preparation of the tent, or a seeking of its cover if camp be already pitched, can alone save the travelling invalid from destruction.

Everywhere in the far Southwest the food question for the invalid is most important,—indeed, dominant. Outside of one or two places, decent food is very rarely if ever found in Western Texas; and it is this difficulty which constitutes the most insuperable obstacle to the consumptive tourist, and almost necessitates the taking of supplies. In my experience, these supplies can be purchased more cheaply at San Antonio than in our Eastern cities, so that it is useless to load one's self down at home.

In regard to the cost of camping in this region, the expense of feeding has already been intimated. The only other expense is that of the outfit, which can rarely be hired, but must be purchased. The cost of an ambulance, two horses, and harness in San Antonio is about four hundred dollars; but to any one who can stand horse-back-riding—and for others the trip must be of doubtful utility—it is much cheaper and at the same time much better to buy ponies, which can be bought at from forty to seventy-five dollars each. At least two are necessary, one for riding and one for carrying. A pack-mule costs a little more than a pony, but is preferable for packing. Whilst one pony will scarcely follow another at all unless continually watched, and a mule pays comparatively little attention to another mule, the respect of the long-eared animal for his more highly-organized colleague is such that he can scarcely be driven away from him. If the travel be leisurely, the Texan pony or pony-mule will keep in good condition by simple grazing. The small Texan mule, which is a cross between the ass and the pony, is as much more hardy and enduring than the large mule as the pony is than the horse. The largest men in Texas seem to select the smallest ponies: so no man need be deterred by his size from bestriding a pony. I have seen four persons—man, wife, and two children—carried cheerily along on the back of a little "burro," *i.e.*, donkey, scarcely bigger than a large Newfoundland dog.

The wet season of Texas may be a serious blot in its yearly climate from the consumptive's point of view. It is usually

considered to be during the months of July, August, and September; but in San Antonio and its neighborhood the early winter months are sometimes quite wet. The fact is that San Antonio is really the extreme southern limit of the arid region, and that in order to get the full benefit of the dry treatment at least much of the year should be passed north or west of that city. The hotel accommodations of San Antonio, however, are bad enough, but beyond it there is probably not, at present, a decent hotel in all Texas. At El Paso a new hotel has been erected, a fine, large structure, which is to be opened this autumn under the management, so we are credibly informed, of one of the leading officers of the Southern Pacific Railroad. If this be true, it will probably be well kept. El Paso is in the very heart of the arid region, is on the borders of Mexico, is a terminal point of the Central Mexican Railroad, and an extremely active place. Unless it be in second-class theatres and in the presence of a garrison band, we know of no superior attractions possessed over it by San Antonio; and if the new hotel be well kept and supplied with good water,—the water of El Paso being, in general, execrable,—it will afford a most excellent place for spending the early winter months. The Central Mexican Railroad is now open for travel to Chihuahua, and is being completed at the rate of three miles a day. It is expected to reach the city of Mexico in a year, and then the health-seeking invalid, by means of the Denver and Rio Grande, the Atchison, Topeka, and Santa Fé, and the Central Mexican Railroads, can travel at will, almost through the length of the dry belt, and, if he choose, enjoy always a temperate climate.

As we have found the summer temperature at San Antonio, Texas, it is very warm but quite bearable. The middle of the day is excessively hot outside of the houses, but almost all the time there is a strong breeze, which makes the temperature quite endurable in a well-shaded room. The rains seem to be usually in the form of tremendous downpours, lasting only a few hours, and the hot sun soon dries the ground, so that the most delicate invalid can walk about freely. With proper suburban accommodations, if such could be found, the consumptive might get through a summer in San Antonio very well, provided he was content to stay in the house

during the hours of sun and find amusement in himself and his books.

Texas offers no attractive mountain-resort. The only place which is high enough to very distinctly affect the temperature is the country about Fort Davis. The sunshine here is intensely hot from 11 A.M. to 5 P.M., but even at these times in the houses the air is cool enough to be pleasant. The nights are mostly cold, requiring blankets, while the early mornings and evenings are delicious. The wet season at this place is very decided, but manifests itself in heavy showers rather than continuous rain. There is some very fine scenery in the neighborhood of the fort: indeed, the fort and town are beautifully situated, and the invalid might very well visit the place were it not for the fact that there are simply no accommodations whatever that a person accustomed at home to anything better than a laborer's cottage, could endure.

El Paso is higher than San Antonio, but my experience does not make it cooler. The whole Texan Rio Grande region is a terror in its heat. The United States post of Presidio, which is several hundred miles below El Paso, has recently been abandoned, chiefly on account of its temperature. As I was informed by the late commanding officer, the thermometer, as early as June, was frequently 110° F. at midnight in an adobe house, the coolest of structures.

From El Paso twenty hours of railroad-riding will take the invalid to Santa Fé, which is in its climate probably the most attractive spot in the whole arid belt. Its moderate elevation, whilst not sufficient usually to affect the consumptive seriously, is enough to give immunity from excessive heat. It affords, therefore, a delightful refuge to any one who finds the Texan summer too severe. It is true that the hot months are its wet season, but during my stay the mornings would be bright and clear, the mid-days swept by violent rain-storms, and the late afternoon beautifully brilliant in sunshine, with perhaps drifting cloud-masses. According to the resident army surgeon, such days were typical of the summer climate of the region. Then there is a large, well-kept hotel, affording a fairly good table, much better than I ever saw anywhere in Texas. A little farther north, on the Atchison and Topeka Railroad, are the hot springs of Las Vegas, which are said to be very well pro-

vided with hotel accommodations, although of this I cannot speak from personal observation. H. C. WOOD.

NOTES FROM SPECIAL CORRESPONDENTS.

CINCINNATI.

MELANO-SARCOMA.—Not long since, Dr. W. H. Falls, of this city, reported a case of melanosis in which the patient had turned absolutely black before dying. The disease being so rare, it was with some interest that, during a recent visit to the city hospital, I learned from Dr. Thomson, the resident physician in charge, of a similar case in the medical wards. The patient is a male, *æt.* 57, carpenter. Previous health good. He had a pedunculated tumor, springing from the integument over the upper lumbar vertebræ, removed by abscission over a year ago. The wound healed kindly, but in a few months in the cicatrix a dark tumor made its appearance, soon followed by others in the subcutaneous areolar tissue of different parts of the body. These small diffuse tumors are from the size of a pea to that of an almond, and as they grow older form an attachment to the overlying integument. They are dark in color, and are pretty well distributed over the whole of the surface of the body, numbering five hundred and sixty-one in all, two hundred and thirty-two being attached to the skin. The patient's general health is fair, and he is under the expectant treatment. He is watched with considerable curiosity by all the pathologists of the city.

The cooler weather of September has brought home most of our citizens who have been sojourning at watering-places, and with them, of course, the family doctor. They might as well have remained in the city, for, according to a paper read before the Academy of Medicine by Dr. Cleveland, a gentleman whose facilities for knowing whereof he speaks are excellent, this summer has been unusually healthy for the young folk, the ordinary summer children's diseases being both scarce and mild.

Students are rushing into the medical colleges with more than usual avidity for the time of year. Professor Seely, dean of the Medical College of Ohio, tells me that the number of matriculates is larger than ever before in the history of the colleges this long before the season opens.

At a fire in the central part of the city nine lives were lost because of the poor means of egress from the upper floors of the building. This, of course, has raised the customary cry for fire-escapes in all of our manufactories where any number of people are engaged above the ground-floor. But few of the fac-

tories are adequately provided with fire-escapes, as every large fire we have abundantly testifies.

PRESCRIBING DRUGGISTS.—This subject has at length grown to be such a nuisance that even our dignified Academy of Medicine has seen fit to take some steps in regard to it. A committee of three—Drs. Ransohoff, Cleveland, and Thrasher—was appointed to see what would best be done. Some of the members were in favor of taking a list of those druggists known to be guilty of unprofessional conduct, and of boycotting them. Others were of the opinion that, unless a radical change in the action of our pharmacists should take place, physicians would be driven to dispensing their own drugs. This, it was said, would also prove an effectual preventive against the repetition of prescriptions without the physician's advice. Speaking of the repetition of prescriptions, Dr. Culbertson said that he knew of one of his prescriptions that had been refilled without his order for the patient and all of the friends more than *two hundred* times. He was paid for but one prescription.

CORRESPONDENCE.

LONDON LETTER.

THERE is a dearth of medical news at present, and everybody, or nearly every leading medical man, is out of town,—a number being at the International Medical Congress, sitting at Amsterdam. The Medical Act Amendment Bill failed to complete its act of parturition, and remains not "still-born," but "unborn." The vigorous action of the threatened corporations, and notably the Scotch bodies, impeded its progress, and, though it had stanch well-wishers in the Cabinet, including the Premier himself, it foundered amidst the breakers of parliamentary factions and the disorder which the Irish Nationalist members created up to the last. We were told that if this bill did not pass there would be no more attempts at medical reform made this century: so there is little prospect of the matter being discussed again in these columns,—at least during the time the present writer is the London correspondent. Such being the case, something may be said as to the attitude assumed by him in his letters. They have created a good deal of comment, both in the United States army journals, and even at home, and the views expressed by him have not always been palatable to his critics. It was never hoped that they would be. There is much left undone that is desirable, though, also, a good deal of what is good has been done. The line taken has been that, due to causes partly outside the

profession, partly within itself, the position of the medical profession is not what it should be, considering its numbers and their individual attainments. For such readers as may hold that the writer lacks patriotism, on the plea "that it is an ill bird that fouls its own nest," it may be well to retort, "Respect begins at home." And the profession must undergo some radical transformation within itself before it will gain the position which, after all, belongs to it. A recent pamphlet has appeared, entitled "The Political Powerlessness of the Medical Profession: its Causes and its Remedies," by Balthazar Foster, the eminent Birmingham physician, which, to my mind, is full of instruction. He points out therein how the Medical Bill of 1858 was the outcome of agitation dating back to that great reform time, 1831. It took the form of a bill drafted by Mr. Wakley (of *The Lancet*) in 1840. When passed, "we won neither of the essentials demanded by the Association: neither a single mode of entering the profession, nor direct representation in the Medical Council." The plea against direct representation was the lack of a register, yet "for a quarter of a century the register has been complete, the medical practitioners of the United Kingdom have contributed from their narrow means one hundred and fifty thousand pounds for the support of a council to represent and defend the interests of the colleges in opposition to the wishes of the profession, and, as a result of our taxation, to leave us the worst-governed medical body in Europe." There is no uncertain sound about statements like these. Such was the sense of failure in the working of the council that the medical-reform committee soon had to recommence its labors. But, though strong representations were made, the council were quite indifferent to them. The medical bills were brought forward, whose fate was failure, until with some prospects the recent proposed bill was accepted. How? "Worn by the long weariness of waiting, broken by repeated disappointment and defeat, we accept this bill as the best we are likely to obtain. But surely such small results after such long labors must convince us of the political impotence of the profession to which we belong." So says Dr. Foster. He then points out what strides physiology had made since 1858, and what was being done when the anti-vivisection agitation checked the progress of experimental inquiry in Great Britain and Ireland. On this the profession was united, and Lord Sherbrooke (then Mr. Robert Lowe), as quoted by Dr. Foster, wrote, "I do not agree with you that, as matters stand now, you ought to submit to any legislation. The law is this: any person may inflict any pain short of torture on any domestic animal, and any torture he pleases on any non-domesticated animal. So long as the law stands, it is a gross insult to the medical profession to single them out as the only excep-

tion to these general rules, and I would advise them not to submit to it. People are very often taken at their own valuation, and I would never admit that you are the only persons with whose liberty it is necessary to interfere." Dr. Foster points out "that if our courage had not been broken by long years of political powerlessness, we should have followed this wise counsel and have obtained better terms." Yet the clamor is still going on for a still more stringent act. Dr. Foster goes on, "It is no wonder to me that a distinguished member of the Upper House, who once fought for us in the Commons, should have said that in all political action we doctors are such poor creatures as to be hardly worth fighting for." The recent action about the arrest of the working of "the Contagious Diseases Act (human) is another slap in the face administered to our profession by the powers that be." Yet our leaders are able men; but, as he says, "our leaders act and speak only as individuals or as the representatives of small bodies of the profession; there is no power of numbers behind them." They do not represent the huge bulk of the profession at large. They represent small parties,—colleges ruled by oligarchies. Then he points out that even the British Medical Association had not direct representation, "and has been met over and over again with the taunt of not applying the system to itself." (This is now effected by the new by-laws which were formally carried at the adjourned general meeting held in Exeter Hall on August 17.) He goes on, "When our resolutions and our petitions go forth, swollen by the chorus of ten thousand, ay, and at no distant day, by the volume of twenty thousand voices, even the dull ears of a House of Commons will be startled into an acute and respectful attention." After thus describing some of the causes of our "political powerlessness," he continues, "Let us now consider those that depend upon ourselves. As a profession we are rapidly becoming, if we have not already become, the most broadly educated class in the community." Some years ago the present Premier said there existed "an opportunity for the medical profession to exercise increased knowledge and a greater share in the leadership of thought." Dr. Foster adds, "Six years have passed since these words were spoken, and we still find the influence slow to come. This is in a great measure our own fault. As a class we are too timid and too reticent; we fail to take our due share in the public work of the communities in which we live." There can be no question as to the truth of this charge. "It will do him harm in practice," is the constant remark made upon any member of our profession who may wish to assert his right to hold an opinion of his own. This timidity, this fear of injury to practice, has made cowards of us as a body. We cannot deny the

justice of Dr. Foster's remark. But, instead of reform in this matter, he will probably only get hard words in private from those who know how true his words are and yet fiercely hate to hear unpleasant truths. Dr. Foster sees the selfishness underlying this crouching attitude, for he says, "With some of us, possibly, there may be a lurking fear that pronounced opinions on political or social questions are apt to injure a doctor in public estimation, and so to lessen his professional influence and his pecuniary profits." But, he adds, "no slavish fear of consequences need check us, for if a calling like ours, which entails so much labor and so little reward, necessitated the mean servitude of reticence from prudential motives, it would justly sink from its position of respect as a free and learned profession." Outspoken words these! He urges that those of the profession who have the time should take more part in public work, for "year by year the statute-book receives provisions, of a social and sanitary nature, that demand medical knowledge for their most effective administration. If we help in this we act for the good of our fellow-citizens, but if, from a too close devotion to work or from a selfish love of ease or from a sorry fear of making enemies, we shrink from this duty, can we be surprised that the public estimate of us sinks, and our influence everywhere fails?" Then he contrasts the few medical men in the House of Commons with the position of the profession in Germany and in France,—Virchow the leader of a powerful party, while "the probable successor of Gambetta is a doctor;" while in Italy no less than seventeen medical men are among those elected for parliamentary work. "It is our apathy and our want of courage in the past that has placed us in the position in which we now are, and I look to the rising generation of the profession to enter on a new and nobler course." This statement is a pretty complete vindication of the truth of statements made from time to time in these letters, which have provoked hostile comment.

Things are not as they ought to be in the profession in Great Britain. A certain line of conduct suits the interests of a certain class of minds, and these are studiously, yea, even remorselessly, followed. The great interests of the profession may go to the dogs, a certain class think, provided their individual interests prosper; and if any voice is raised to ask for anything else, they immediately denounce the offender in the press, if they dare; if not, they can backbite him. The difficulty of the bolder units taking the action Dr. Foster holds desirable is, not that the public would resent their coming forward in public matters, but the timid and the envious units would never cease privately to insist that such position was professionally injurious until the public would believe them. The better part of the profession is weighted over

"the load-line" by the selfish element. Dr. Foster thinks this too, for he goes on, "But power will not come to those who stand aside and look on either cynically or timidly at the strife of parties. We must hold ourselves like men willing to take our share in the struggle; we must remodel our institutions; we must organize and consolidate our profession, and infuse into our ranks the self-respect and dignity that come from discipline." It is abundantly clear that a great transformation is needed before the profession can take its proper place,—a transformation of individual thought in many cases. Instead of a truckling policy which those who believe in it force more or less completely upon others who do not believe in it, and who would wish to do rightly, uprightly, and openly, we require to step out with the "sure and certain step of men."

It is, indeed, "the lurking fear of lessened professional influence and pecuniary profits" which induces the weak to combine to press down the strong; it is the rule of cowardice, of want of strict faith to each other, which has emasculated our profession and rendered it politically "impotent." An illustration of the powerlessness of the profession as a body has been furnished by the recent conflicts betwixt the profession and the nursing-sisters. The late Prof. James Symes, of Edinburgh, always asserted a weakness for the old-fashioned nurse, who was a menial (and not always above a reasonable suspicion of a liking for a drop of something now and then), as compared to the modern sister, who claims the feelings and the culture of a lady. But he, with all his foresight, probably never dreamed that the day would come when the nursing-sister would attempt to rise superior to the medical man: yet, from what has appeared in the press from time to time, it would seem that the nursing-sisterhoods, by firm combinations and alliances with members of the governing bodies, have been able to drive the profession into a corner at times. For years Guy's grand old hospital has been before the public as the seat of internal discord; though fortunately it has of late been less conspicuous for such dissension. Ugly rumors have been in circulation for some time about the condition of King's College Hospital. It was nursed by the sisterhood of St. John's House, an earnest but arbitrary body, which gave itself airs of a very unwonted order. The hospital was really under this feminine sway, and as an institution for the teaching of medicine its utility was greatly shaved down by the rules and regulations insisted upon by the dominant ladies; dressing was made as irksome as possible, and the object of instruction was sacrificed to the caprices—for they deserve no higher term—of the sisterhood. Religious enthusiasm is a very fine thing; self-devotion is noble; but the history of religious nursing-sisterhoods

teaches the sad lesson that a woman must possess a very great amount of good principle to carry safely any load of religious enthusiasm; without it the latter carries her away on a flood-tide against which she can make no effectual resistance. Self-abnegation, the merging of the individual in the aggregate, may end in the most assertive self-worship; everything may be sacrificed to formal prayers, which do not seem to carry with them the lesson of humility; spiritual pride is a noxious weed which is apt to flourish in a rank growth of religious feeling; and religious thought is not always accompanied by a commensurate growth of godly action. The attitude adopted by the sisterhood of St. John's House, unless these pious women are sorely belied, has not always been one illustrative of Christian humility, or in full and complete accordance with the lessons taught in the Sermon on the Mount. The devotion of the individual to the community is seen as much in the insect world, amidst bees and ants, as in any of the religious sisterhoods, where the workers are also sexless females,—sexless by the act of the Creator in the one case, sexless by their own will and vow in the other. The devoted sexless female is no longer an individual, she is a unit of a community; and her merging of self is complete. But the actions of these communities are not always defensible, and King's College Hospital has drifted into increasing difficulties under the sway of the sisters of St. John's House. A great portion of its invested funds has of late been sold out in order to enable the present régime to carry on its practices; and after the last annual meeting it was said that notice would be given to the sisterhood as one part of the reform which was evidently becoming imperatively necessary if the institution was not to be looked upon as being hopelessly insolvent. Further, the "aggressive attitude" of the matron had long been an offence to the staff and the students,—two not altogether unimportant matters in a teaching-hospital. "At length, however, the acme of toleration has been reached, the resignation of the matron insisted on, and, after prolonged refusal, received," says one of our medical journals. Where was the personal self-respect of the fanatic, that she could not go when her presence had become so objectionable that it was decided to suffer it no longer? How was it she clung frantically to her place, and required reiterated intimation that go she must? But a more curious chapter in the history of religious arrogance is furnished by the fact that the forced resignation of the matron was followed by the sudden withdrawal of the sisterhood without notice, so as to leave the hospital crippled. Where were their professions of Christianity and their vows upon that occasion? It is said that their amiable malignity went further than this: the nurses were called in, and,

on pain of instant dismissal, commanded to resign their posts. It is quite clear that every consideration but their own wilful caprice, their own weakness, wickedness, and folly, had been flung to the winds. Prevented from doing further injury to the institution whose bane they have been for long, their last act, like the fleeing Parthian's arrow, was to try to inflict a grievous wound on the institution by leaving it utterly helpless. "All honor, be it added, to the nurses who, notwithstanding the absence of pretensions claimed by 'lady' nurses, remained with true womanly pity at their posts beside the beds of suffering patients, while their cultivated 'superiors' followed in the wake of the indignant matron." The journal continues, "Spite of the temporary inconvenience, the authorities of King's may congratulate themselves on a good ridance of women who could be guilty of so grave a dereliction of duty; and there can exist no doubt that this exhibition of feminine malice has done a great deal to alienate the sympathies of the right-feeling section of the supporters of these sisterhoods." Another journal, commenting on the action of the matron and sisters in their impish malice in trying to cripple the hospital as their final act, says, "The whole circumstances illustrate the danger of handing over the nursing of a hospital to a foreign power, and the difficulties resulting from the exaggerated pretensions of some nursing-sisterhoods." Yet, despite these outspoken judgments, in harmony with notorious facts, it is curious to see a letter from one of the supporters of the ladies, in this journal: "Sir, you are incorrect regarding your statements concerning the lady nurses at King's College Hospital, as they were discharged in the most unjust and peremptory manner, and at great inconvenience to themselves, by the members of the Council, merely because a little since the matron, Sister Aimée, reported a case of supposed irregularity by a doctor towards one of the patients. I speak as a parent of one of the lady nurses.—M.D." Poor victims! martyrs to a sense of duty! "Supposed irregularity." It might have been as well, possibly, if she had been sure of her ground.

This piece of meddlesome impertinence is the plea, then, for the grossest ill usage to those unoffending creatures. We see "asinine paternal pride" in many of its phases; but what can be expected of the social position of medicine when such traitors are in its ranks as this M.D.? His intellectual spectacles are sadly chromatic, I fear; his duty to his profession a poor withered limb compared to his fatherly interest in his "lady-nurse" daughter. He would have done much better if he had adopted the old plan, "whipped her and put her under the pump," than inditing such a pitiable production. Perhaps, after all, our position is quite as good as we deserve.

J. MILNER FOTHERGILL.

PROCEEDINGS OF SOCIETIES.

THE AMERICAN GYNÆCOLOGICAL SOCIETY.

THE American Gynæcological Society held its eighth annual meeting at the Hall of the College of Physicians, Philadelphia, September 18, 19, and 20, holding morning and afternoon sessions. Gilman Kimball, M.D., of Lowell, Massachusetts, President of the Society, and Albert H. Smith, M.D., Vice-President, occupied the chair during the meeting. The membership of the Society is limited to sixty Fellows, about half of whom were in attendance, besides a number of invited guests and members of the profession. The papers read were up to the standard, and the discussions were able and spirited. After the morning sessions lunch was provided by the resident Fellows, and on Thursday evening a supper was given at St. George's Hall, by the Philadelphia Obstetrical Society, which passed off pleasantly. Altogether the meeting was declared to be as successful and satisfactory as any which had been held by the Society.

FIRST DAY'S PROCEEDINGS. — *Morning Session.*

The President called the meeting to order, and the Secretary recorded the following names as present: Fordyce Barker, New York; Robert Battey, Georgia; B. B. Browne, Baltimore; William H. Byford, Chicago, Illinois; J. H. Byrne, Brooklyn, New York; Henry F. Campbell, Augusta, Georgia; James R. Chadwick, Boston, Massachusetts; Edward L. Duer, Philadelphia; T. Addis Emmet, New York; Frank P. Foster, New York; William Howard, Baltimore; J. V. Ingham, Philadelphia; A. Jackson Reeves, Chicago; J. T. Johnson, Washington, D.C.; Gilman Kimball, Lowell, Massachusetts; W. T. Lusk, New York; Matthew D. Mann, Buffalo, New York; C. D. Palmer, Cincinnati, Ohio; Theophilus Parvin, Philadelphia; Thaddeus Reamy, Cincinnati; J. C. Reeve, Dayton, Ohio; Albert H. Smith, Philadelphia; R. S. Sutton, Pittsburg, Pennsylvania; Ellwood Wilson, Philadelphia; H. P. C. Wilson, Baltimore; Ely Van de Warker, Syracuse, New York. Some others were in attendance later whose names do not appear.

An Address of Welcome on behalf of the resident Fellows was delivered by Edward L. Duer, M.D. The Secretary read a communication from the Council announcing that the following had been made members by invitation: Alfred Stillé, M.D., President of the College of Physicians of Philadelphia; William M. Welch, M.D., President of the Philadelphia County Medical Society; Richard A. Cleemann, M.D., President of the Philadelphia Obstetrical Society; James Tyson, M.D., President of the Philadelphia Pathological

Society; Robert P. Harris, M.D., of Philadelphia; and I. R. Page, M.D., and Robert T. Wilson, M.D., of Baltimore, Maryland.

Superinvolution of the Uterus.

The first paper read was by Joseph Taber Johnson, M.D., of Washington, D.C., upon superinvolution of the uterus. He said that although this morbid condition was recognized and described thirty years ago by Sir James Simpson, and is not an uncommon affection, yet it is infrequently referred to in text-books. Frommel found that it was present in about one per cent. of gynæcological cases, and Simpson thought that the number of cases would be found to be much greater if they were properly looked after. It is to be differentiated from atresia of the uterus, undeveloped uterus, or one which has been changed by inflammatory processes. The condition of superinvolution is one of excessive action of the physiological processes of involution occurring after the cavity of the uterus has been distended by any growth, normal or abnormal: thus involution to an exaggerated degree may follow parturition or abortion, hydrometra, physometra, hydatids, the removal of large fibroid tumors, etc. He reported four cases in his own practice.

Case I., aged 26, commenced to menstruate at 14 years of age, and continued to do so regularly until she became pregnant, five years ago, and was delivered with the forceps; the child was still-born. On the third day symptoms of septicæmia developed, and a laceration of the cervix and perineum was found, but no metritis. She subsequently made a good recovery, except that she had an offensive leucorrhœa and sick headache at her menstrual periods. After two years had passed, her abdomen began to enlarge, and she supposed herself pregnant again, and made the usual preparations; her headaches now were relieved. About the time that she expected her confinement the abdomen rapidly decreased in size, and the tumor disappeared. Her menses had not appeared since her former pregnancy, although her health was good and she had gained flesh. Upon examination the uterus was found to be less than two inches in depth; the edges of the laceration had never healed. He performed trachelorrhaphy last year; the operation was successful in curing the offensive leucorrhœa, backache, and headaches, and in restoring sexual appetite. The general improvement was marked, but the menses have not returned, although electricity and the ordinary treatment were employed. She has now the appearance of robust health, although she does not menstruate. Simpson and others class these cases as invalids, and as subject to nervousness, and predict early death. Her case is an exception to this rule.

Case II., now 30 years of age, had been married ten years, and had a miscarriage

several years ago, from which she made a good recovery. In addition to this history, she reported that four years ago her abdomen had swelled, and afterwards she discharged a large amount of water from the vagina. At the time she consulted the reporter her periods only lasted for one day; sexual appetite was preserved, and she was anxious to have a child. The uterus was found to measure less than two inches in depth. Electricity, massage, and the usual treatment was followed, but without marked success; her menstrual period extended to seven days, and then, after coitus, stopped for several months, when she thought herself pregnant again, but she was disappointed. No benefit was derived from the treatment.

Case III. menstruated at her seventeenth year. She was 29 years of age, and had been married five years, but had never been pregnant; it was, therefore, not truly a case of superinvolution, as no history could be obtained of distention of the uterus, but her appearance was exactly like the preceding case. The uterus seems insensitive, freely movable. Having speared it with a sharp knife, applied electricity, etc., no marked result was obtained.

Case IV. was a patient in the Provident Hospital. She had had two children, both of whom died, and she was anxious for another. Her periods lasted only a few hours. The uterus measured only one and three-quarter inches; it was, like the others, insensitive. Nothing was obtained by treatment. It was evident that she had reached the climacteric prematurely; none of her family, however, so far as she knew, had changed at such an early age.

The results of these four cases are certainly not encouraging, but they are as good as those obtained by others. Simpson reported several cases with like results. Whitehead reports a case in which the uterus and ovaries completely disappeared after labor. Scanzoni recognized atrophy of the uterus after labor. Prolonged lactation has also been assigned as the cause by Frommel. It could not have been the cause in two of these cases, because in one the child was still-born, the other was a miscarriage. Dr. Edes considers that in some cases it is the natural result of parturition: the reproductive powers have been exhausted by one supreme effort. From whatever cause it may arise, this condition exists, and should be recognized: electricity should be tried for its relief, but the cases are usually incurable.

DISCUSSION.

Dr. Fordyce Barker, of New York, being called upon by the Chair to open the discussion, said that with regard to the term superinvolution, some authorities would restrict its use to a reduction in the size of the uterus below the natural size of the organ, after con-

ception. He thought it perfectly proper to apply the term to any case in which this process occurs to an extreme degree, as after the removal of fibroid tumors, false conceptions, or other objects within the uterus. It seemed to him as if it might also be applied to some cases of uterine catarrh in which these identical changes have occurred, and, in fact, to all cases where retrograde processes have gone on to an abnormal extent. With regard to its frequency, the practitioner with a large consulting-practice will be likely to see a greater number of these cases than other physicians. He believed that he saw two or three cases every year.

He would, in conclusion, refer to another point not mentioned by the writer of the paper, but which had been taking form in his mind for several years. He had never published it, but had mentioned it to friends; he had never seen it referred to in medical literature. In making his decision whether we shall allow the patient to undertake the expense of treatment, he always took the precaution to examine into the condition of the ovaries,—if they are associated in the diseased condition and are atrophied or defective, or if they are active in their functions. If the latter is the case, and at each monthly period there is great systemic disturbance, there is an effort of nature to relieve the plethora of the pelvic organs, the patient will be one who will be benefited by treatment; the others, where such nervous symptoms are absent, will not be benefited. He cited the following case. A lady 24 years of age, the wife of a physician, owing to an accident, being in a carriage during a runaway, had an abortion at the sixth month of pregnancy. About two months later, when menstruation should have returned, there was great constitutional disturbance, backache, etc.; but there was no discharge. She was a large, strong woman, weighing 208 pounds, and in apparent health. On examination, the uterus was found to be small, extremely small, and the cervix did not show the slightest evidence of a past pregnancy. She was kept under treatment; electricity was systematically applied, the cervix was dilated with bougies, and she was given a pill containing ox-gall, aloes, sulphate of iron, and other remedies as needed. After three years' treatment she became pregnant, and he delivered her of a living child with the forceps.

He recalled another case of a lady, who, while travelling in Europe, from over-fatigue had a miscarriage, which was attended with great hemorrhage. She never menstruated afterwards, although for several days each month there was great disturbance of her nervous system, each period terminating in a sharp attack of diarrhoea. After being put on a similar course of treatment, she also became pregnant and was delivered of a living child.

The main point in the prognosis and in the treatment is to discover whether the superinvolution of the uterus is accompanied by loss of the function of the ovaries, or is associated with active ovaries: in the latter condition, the uterus may be restored; where this is not the case, treatment is of little use.

Dr. A. Reeves Jackson, of Chicago, was surprised at the statements of the paper as to the comparative frequency of this condition. He had himself seen only a single case, and that was of doubtful diagnosis. Several years ago, a woman was admitted to the hospital with which he was connected, in Illinois. She was 32 years of age; her youngest child was five years old. She had been obliged to feed the child artificially because of insufficient lactation, and had weaned him entirely at five months. When she came under observation, the breasts were flabby and withered, the skin on her neck was wrinkled like an old woman's. There was very marked atrophy of the uterus, even more than usual in senile atrophy; the ovaries could not be detected at all. He finally succeeded in passing a probe through the very small os, but was surprised to find it pass in several inches: he discovered, to his dismay, that he had penetrated the fundus uteri. He did not know at that time that this accident is neither very rare nor very dangerous; in this case it produced no bad symptoms. He afterwards inserted a galvanic stem-pessary, but without results. Here is a case of difficulty in diagnosis: was it a case of premature climacteric? He thought that this might not apply to many cases, however. But here the atrophy of the uterus is due either to superinvolution or to premature menopause. The practical point in diagnosis submitted by the last speaker is well worthy of consideration.

Dr. Ely Van de Warker, of Syracuse, called attention to a possible source of error in diagnosis in superinvolution of the uterus. After laceration of the cervix there is often marked atrophy of the cervix, which does not extend to the fundus. He had never seen it except as the result of laceration. The length of the cavity of the uterus itself remains unaltered, but that of the cervical portion is very much reduced, and more in the posterior than in the anterior lip. Why it should be more marked posteriorly than anteriorly he could not say. He could easily see how a large proportion of the cases reported as superinvolution of the uterus might be of this character, and was inclined to think that one of the cases mentioned in the paper was of this character.

Dr. H. P. C. Wilson, of Baltimore, regarded the condition as extremely rare: in all his practice he had seen only two or three cases. He endorsed the remarks of Dr. Barker as to the distinction between those who can be benefited by treatment and those who cannot be. Where the ovaries are not active he had not been able to get the slightest benefit from

treatment, but in the others, where the ovaries remained normal, he had been able to benefit his cases.

Dr. Robert Battey, of Georgia, confirming the remarks made by Dr. Barker, said that atrophy of the uterus is a constant result of the operation with which his name had been connected. In most of these cases of oöphorectomy the uterus is not diseased, but is healthy; but its function is interrupted by the operation. He believed that superinvolution of the uterus is due, therefore, rather to disease of the ovaries than of the uterus, because he has known this to occur very commonly after removal of the ovaries. He had never seen it follow removal of the Fallopian tubes alone, and in this view differs from Lawson Tait; indeed, he doubts if it ever occurs from simple removal of the tubes.

The best remedy is electricity, applied so as to pass the current through the ovaries rather than to the uterus itself. Dilatation of the cervix with sponge tents should also be commended.

Dr. William H. Byford, of Chicago, said that he had listened with interest to the communication of Dr. Johnson because it is on a subject which has not been exhausted by the profession. He thought that great confusion and want of distinct knowledge obscured the whole question at present. He inquired, Is there any difference between superinvolution and atrophy, or is superinvolution a step on the road to atrophy? He believed himself that a decided difference exists between superinvolution and atrophy, although in the great number of cases it is merely a stage in this process. He would consider superinvolution as a condition in which the uterus preserves its normal characters and its normal functions, though reduced and dwindled in size. He agreed with the first speaker that the cases should be divided into the simple form, involving the uterus alone, and the complicated, in which the ovaries participate; for although the process may go on in both *pari passu*, yet it may go on to a much greater extent in the uterus than in the ovaries. He believed that if the ovaries should become very much reduced from superinvolution, the uterus necessarily becomes so. He also agreed with the statement that when the ovaries partially retain their functional activity the case may be cured. Wherever the symptoms indicate that the ovaries are still active, we may get the best results from treatment; when these symptoms are absent, no hopes can be entertained. He believed that the time would come when, in the development of our knowledge of these processes, what superinvolution is and how it is brought about will be better known than it now is. In the mean time, the treatment mentioned, with the use of a pessary to keep up irritation between the periods, in the hope of stimulating local congestion, might be of service.

Dr. Henry F. Campbell, of Augusta, Georgia, said that he did not consider it necessary to the existence of superinvolution that there should be either atrophy of the ovaries or atresia of the uterus. He referred to a case in which there had been extreme distention, which was sufficient to cause barrenness, although ovulation apparently continued. He was called in consultation to see a case in which the attendant physician declared himself unable to determine whether the fluid was in the peritoneal cavity or in the uterus. The woman was about six months pregnant. She had an immense abdomen, and it was very tense. The woman was obliged to lie upon her side on account of this enormous collection of fluid, and her condition was serious. He determined to bring on premature labor, and did so, and a fetus was discharged, with about a pint of amniotic fluid. Fearing that they had made a mistake, they were preparing to tap the abdomen with the trocar, when, upon making a preliminary vaginal examination, another bag of water was found protruding from the uterus, which evidently contained a blighted twin fetus, with dropsy of the amnion. The membranes were punctured and gallons of water were expelled. The patient rapidly recovered. Although she had had children regularly every fifteen or eighteen months before this occurred, she never conceived again; yet the menstrual nixus and menstrual discharge continued. The ovaries continued physiologically active, but the woman never became impregnated again. The theory on which he had accounted for this sterility was that the over-distention of the uterus had resulted in a loss of muscular power, just as over-distention of the bladder sometimes causes permanent weakness and impairment of function. He inquired if this theory might not account for some cases of barrenness after extreme distention of the uterus, without reference to the ovaries.

Dr. Johnson, in closing the discussion, accepted the point raised by Dr. Barker, which seemed to be an important one, both in diagnosis and in treatment. There is a difficulty, however, in dividing the cases absolutely, but their condition at the menstrual periods, will serve as a guide as to whether the ovaries are active or not.

The distinction made by Dr. Van de Warcker he coincided in, and he had been of the opinion himself for a long time that the case referred to was really one of atrophy of the cervix; but such cases usually recover after trachelorrhaphy, and menstruation returns. It was not so in her case, although her health is robust and the operation was successful in restoring the parts.

In reply to Dr. Jackson, he said that he had not claimed that it is very frequent, but that it occurs often enough to demand our attention. Dr. Byford's division is essentially that of Dr. Barker. The treatment

recommended was that which had been pursued, and which he would continue, and will report further results at a future meeting.

The Importance of Cleanliness after Surgical Operations.

R. Stansbury Sutton, M.D., of Pittsburg, read a paper, in which he gave the results of his observations while on a visit to some of the great clinics in Europe. He directed especial attention to the fact that a great change had taken place in surgical methods within a few years, and this is especially evident in the cleanliness which surgeons everywhere endeavor to secure during surgical operations and in the treatment of wounds. Formerly it was thought that all the bad influences came from within, and wounds were left open and encouraged to discharge freely, in order to purge them. Now there is a return to the earlier treatment of Galen, and wounds are closed and protected as much as possible from outside sources of infection. The cell theory led naturally to the germ theory of disease, and, as the microscope kept pace with progress, organisms were detected in the discharges from wounds, and these were regarded as noxious agents.

The object of the treatment introduced by Lister was to keep these septic organisms out of wounds, and he introduced carbolic acid and insisted upon cleanliness. The result of his teachings is that surgery has achieved better results than ever before; and yet the most active opponents of Lister are those who adopt his principles of treatment, simply modifying it by omitting the spray, or substituting other agents for carbolic acid. He denied that carbolic acid is synonymous with Listerism, or even necessary to it. Some antiseptic may be found that is better for the purpose; it is not essential. Strict attention to cleanliness in all the details of the operation, in order to keep the wounds aseptic, is the great principle of Mr. Lister's treatment. Keith is such an expert in cleanliness that he can dispense with carbolic acid; and Lawson Tait exercises the greatest care to prevent infection of wounds, so that he also can dispense with this agent and yet have good results. German surgery was formerly considered extremely dirty; now a visit to the operating-rooms of Esmarch, Volkmann, Schroeder, Nussbaum, Koeberle, and others will show the most minute attention to cleanliness, although various minor modifications of the Lister treatment have been made. Listerism, or something else, has taught them the necessity of cleanliness.

DISCUSSION.

Dr. Barker asked the Chair to call upon Prof. Gross, the Nestor of American surgery, to open the discussion, as he was in the room.

Prof. Gross said that he was much obliged to the Society for the honor, but he must decline,

as he had come merely to listen and be instructed, and not to talk.

Dr. T. A. Emmet, of New York, in response to an invitation from the President, stated that he had nothing to add to the statements in the paper; he agreed with the lecturer perfectly. He had previously expressed the opinion that the death-warrant of the patient is too often carried under the finger-nail of the surgeon; and, since he had been abroad on a visit to the clinics mentioned, he had trusted to soap and water in preference to other antiseptics. The operator may keep himself clean, but it is very difficult to control the assistants. Lawson Tait even goes so far as not to allow any one to touch the wound or the sponges that he uses except himself, and declines the aid of an assistant.

Dr. Wm. T. Lusk, of New York, said that the paper that had just been read contained statements that would be accepted by the most ardent Listerite. He would, however, take exception to the remark that the carbolized spray should not be used unless the surroundings are impure. He thought that the danger of the spray had been exaggerated. Cleanliness, of course, is required, but, in addition to ordinary cleanliness, Mr. Lister aimed by his methods to exclude impalpable causes of disease by the use of carbolic acid. Though micrococci resist five-per-cent. solutions of carbolic acid, yet the bacteria which cause putrefaction are destroyed by this agent. He could not feel prepared to give up the spray, as he had used it successfully in operations at the hospital which he would not dare to perform without it, as such operations previous to the use of the spray were generally fatal. He had operated for ovariectomy at Bellevue Hospital in a tainted ward with perfect success under the spray, although some of his colleagues were of the opinion that under ordinary circumstances it would be simply murder. Last winter he had operated upon four cases, all presenting peculiar difficulties: in only one of them was there a rise in temperature as high as 102° , and that only for a few hours. He believed that he could not obtain as good results without the spray as with it.

Although the lecturer states that all of Keith's cases in which the spray was used died, and all those operated on since recovered, it does not follow that they died because of the spray. He could not forget that when he visited Keith, some years ago, when he had reached his forty-fifth successive successful case of ovariectomy *with the spray*, he got out his case-books to prove that the London men must come to the spray. He also stated that, whereas before the use of the spray he felt obliged to visit his patients three or four times a day, since employing it he only was obliged to visit them once a day. Certainly, very much must be attributed to experience in operating: this is the secret of Mr. Bantock's

success. Mr. Lawson Tait carries out all the details of the antiseptic treatment, except cleanliness. After watching him operate, one can only arrive at one conclusion,—his exceptional results are due in great amount to his personal skill and address. In removing the ovaries he makes an incision only three-fourths of an inch in length; adhesions are torn up by the finger. He operates very rapidly, requiring only a few minutes: the result is that there is very little shock, and one of the principal conditions leading to septicæmia is wanting. While such an operator may safely do without the spray and other details of Listerism, yet for operators of less skill, and under less favorable conditions, the spray is still needed.

Dr. Wilson, of Baltimore, said that the profession owes a great debt of gratitude to Mr. Lister, and he had been surprised to find gentlemen crying out against Listerism and at the same time using all the details of Listerism except the spray. He had the pleasure of seeing Mr. Keith operate lately, and this operator told him that no woman ought to die of ovariectomy if she came for treatment sufficiently early. The greater success from the operation lately may be due to the fact that patients are willing to have the operation performed, instead of putting it off until they are ready to die. He thought it possible to use too much carbolic acid, and, on account of this, he does not employ the spray during the operation, but before it, in order to purify the air. Mr. Keith said that he was struck more and more with the wisdom of Lawson Tait in not having many assistants. The surgeon cannot be responsible for his assistants, although he may be clean himself.

Dr. Campbell said that surgeons were careful with regard to their patients before Mr. Lister talked about carbolic acid at the International Congress, and he thought it a great injustice to ascribe all cleanliness, past and present, to any one man. His statistics of amputations are as good as those of the surgeons who use carbolic acid, and he mentioned a case in which blood-poisoning and delirium were caused by carbolized solutions.

Dr. Sutton, in closing the discussion, protested that carbolic acid is not essential to Listerism, and believed that in abdominal surgery it had done more harm than good.

In reply to Dr. Lusk, he said that the statement that Lawson Tait uses Listerism, except the spray, was incorrect. He does not use a single drop of carbolic acid for his operations. The only antiseptic that he uses is boiling water; and, instead of using carbolic acid for his sponges, he carefully washes it all out in clean water before operating. The speaker believed him to be perfectly honest in his antagonism to Listerism.

Tait and Bantock, of the Samaritan Hospital, stand alone in their opposition to carbolic acid, and he would not hesitate to say

that he thought that the day of the carbolic acid spray is over. As far as the object of disinfecting the room is concerned, the spray is simply worthless: if the floor be sprinkled, so as to keep the dust from rising, it will be more to the purpose.

The question of assistants is very important. Keith has only one, Tait very few, Billroth very many. There is also a great difference as regards the character of the cases. Billroth operates upon everything that deserves a chance of life. Some others, on the contrary, select their cases carefully. He, therefore, would place no reliance on statistics, in this class of operations particularly.

Afternoon Session.

The following were made members by invitation: Prof. S. D. Gross, of Philadelphia; R. P. Maury, M.D., of Memphis, Tennessee; and W. P. Chunn, M.D., of Baltimore.

Hot Water in Secondary Hemorrhages after Pelvic Operations.

Dr. Albert H. Smith read a paper advocating the hæmostatic properties of a stream of hot water after operations on the pelvic organs, as well as to prevent post-partum hemorrhage by using it immediately after the placenta has been expelled. He had found that hot water would check hemorrhage even in a hemorrhagic diathesis, and expressed surprise that Dr. Skene had considered this a contra-indication to certain operations. The following points he submitted for discussion: (1) the great superiority of the hot-water douche over all other means of arresting hemorrhage; (2) its efficiency when carried directly to the bleeding surface; and (3) its simplicity.

DISCUSSION.

Dr. Reamy said that he was in the habit of irrigating the surface with a stream of hot water during operations upon the perineum, thus avoiding the use of sponges.

Dr. H. P. C. Wilson approved of the use of hot water for the purpose named both in pelvic operations and in post-partum hemorrhage. He referred briefly to a case in which he had saved a patient's life by its use, where free bleeding had followed removal of both ovaries through Douglas's cul-de-sac; he had injected gallons of hot water, washing out large clots from the abdominal cavity, and had succeeded in stopping the bleeding.

Dr. Campbell recalled a case, many years ago, of vesico-vaginal fistula in which he had to relinquish the operation on account of the hemorrhage. He thought that with the aid of hot water he might have finished it, but he did not know of its use at that time. In post-partum hemorrhage he uses warm water to wash out the uterine cavity, and then injects iodine. He called attention to an instrument—the metroclast—which has a sort of wire cage around the long nozzle of a Davidson syringe.

By this expedient the water is allowed to escape as rapidly as injected.

Dr. Mann said that he had used it a great deal in post-partum hemorrhage and after removal of fibroid tumors with success, but he had a case two years ago where the injection of hot water failed to stop the bleeding. It was a case of cancer of the cervix, in which he had removed the intravaginal portion of the cervix and had checked all bleeding; but, seeing a small piece that he thought should be removed, he snipped it off with the scissors, and free bleeding followed. He injected vinegar and hot water, but without the slightest effect. He tamponed, with no better success. He then applied Paquelin's cautery, and stopped the bleeding, but the patient was exsanguine, and died in ten minutes. Dr. Mundé had a similar case, both being reported at the New York Medical Society on the same evening.

He would not dispute the value of hot water as a hæmostatic, but thought that we should not place reliance upon one form of treatment alone.

Dr. Goodell thought that Dr. Mann had asked too much of the hot water, as the hemorrhage was evidently from a large-sized vessel. He had found it extremely valuable where oozing occurs, especially after ovariectomy. He thought it effective even beyond the limit of its actual contact, for in cases of menorrhagia it will check the bleeding, although only thrown into the vagina. Vinegar, on the contrary, must reach the bleeding surface in order to do good. He would consider hot water as having a double advantage in its local and its indirect action. For open wounds he prefers vinegar, and in post-partum hemorrhage he uses hot vinegar.

Dr. Barker called attention to one point of importance in attempting to decide whether hot water is the best agent to use in a given case or not. The hot douche requires some time—ten or fifteen minutes—to check bleeding; in some cases a more prompt hæmostatic would be needed to save life. He mentioned a case of hemorrhage from laceration of the vagina which resisted hot water for half an hour, and one of cancer of the cervix where bleeding persisted in spite of the hot water. In the latter case he applied a compress dipped in Squibb's ergot, and a tampon, which stopped the bleeding.

Dr. Byford fully concurred in the conclusions expressed in the paper.

Dr. Campbell said that he was reminded that there are cases in which it is important to decide the greater appropriateness of one hæmostatic over another. In cases of post-partum hemorrhage, anything that will stimulate the muscular fibres of the uterus to contract will stop the bleeding. In cancer it is different: here a styptic would be necessary. Iodine would be of no use in cancer, because it is not a styptic; but it is useful in post-

partum hemorrhage, because it stimulates the uterus and causes contraction.

Dr. Smith said that with regard to Dr. Mann's case he would say that he had had a precisely similar case in which the hot water was used successfully. In order to get the desired effect, it is necessary to have the hot water reach the bleeding spot; if profuse, the bleeding may prevent the hot water from reaching the spot. In such cases it is necessary to elevate the hips of the patient, so that the blood may gravitate to the upper part of the body: then the bleeding becomes less, and the hot water acts better. He would not claim that there might not be cases in which it would be inapplicable, as no remedy in medicine can be used in all cases without exception. He simply called attention to the simplicity, convenience, and efficiency of hot water. In reply to Dr. Goodell, he thought that the principle was the same whether the hot water was used with vinegar or with any other agent, such as carbolic acid or Labarraque's solution.

With regard to having a more prompt hæmostatic, he would be very glad to get one, but he had never seen anything in the use of ergot to warrant its substitution for the hot water. In reply to Dr. Campbell, he would state that he had seen cases after labor where the uterus contracted firmly, but blood spurted away in a stream as large as a goose-quill, and it was stopped by hot water. He thought that this remedy, though perhaps not available on all occasions, is valuable, easily applied, and rarely fails to check hemorrhage.

Some Points connected with Dysmenorrhœa.

C. D. Palmer, M.D., of Cincinnati, said that dysmenorrhœa is a common affection, and troublesome to treat, and should therefore have its pathology well understood. He gave a brief review of the mechanical theory of Mackintosh, Simpson, Simes, and others, and stated that while obstructions undoubtedly do exist and may give rise to painful menstruation, he believed this to be the case in comparatively rare cases. The objections to the mechanical theory of dysmenorrhœa are (1) the want of uniformity between the cause and effect, the same amount of obstruction giving rise to different symptoms in different cases. The most severe sufferings may attend a condition of the canal which admits the passage of a moderate-sized sound, or which may show no stenosis whatever. In those where the local obstruction is the greatest the symptoms are often less marked than others affected to a slight degree, and the pain may reach its climax without there being anything in the uterine canal to account for it. (2.) Constitutional treatment is more effective than local measures: chalybeate tonics and agents which increase the flow of blood relieve the pain rather than increase it. (3.) The course of the menstrual blood may be as uninterrupted in a curved uterine canal as in a straight one,

but congenital cases of flexion are attended by dysmenorrhœa, but similar conditions coming on in adult life rarely are. (4.) There are cases of dysmenorrhœa in which no fault of conformation can be detected in the uterus or any of its surroundings. On the other hand, atresia may exist without pain. From these and other considerations he concluded that the mechanical theory of dysmenorrhœa was not demonstrated.

Dysmenorrhœa is, therefore, a functional disorder of the uterus which is at its base a neurosis. It is especially due to bad inheritance, poor hygiene, and vicious methods of education.

In treatment, he recommended local measures to reduce the extreme sensitiveness of the uterine mucous membrane, such as dilatation by bougies, and various applications, also electricity. In addition, constitutional treatment is required by open-air exercise, good food, iron, arsenic, phosphorus, nuxvomica, quinine, etc. He believed that stenosis is more frequent at the outer than at the inner os, and this explains the greater frequency of barrenness than of dysmenorrhœa. It is easier for the menstrual fluid to escape than for the spermatic fluid to gain entrance. As in these cases the retention of the menstrual fluid may cause secondary changes, it is better to dilate early. He preferred dilatation by bougies to incision, which has been too much relied upon and has been overrated. Time has fixed the value of incision of the cervix, and has greatly limited its range of application.

DISCUSSION.

Dr. Chadwick agreed with the author of the paper: he had to a very large extent given up the idea of obstructive dysmenorrhœa. He rarely used incisions except in cases of constriction of the canal at the external os. The dysmenorrhœa of many women is due to spasmodic contraction of the uterus from peristaltic action of its muscles, from some local cause of irritation, such as catarrh, just as is seen in fissure of the anus; in others the disease is purely a neuralgia. When the neurotic element is strong he gives before each menstrual period bromide of sodium (gr. xx, three times a day), and during the attack he gives fluid extract of coca and ammonium chloride. He never gives such patients morphia.

He had not for many years met with a case in which dysmenorrhœa was due solely to flexure of the uterus, but he had found this condition coexisting, both being due to imperfect nervous development.

Dr. Barker said that he fully concurred in the views of the author of the paper. He believed that the proportion of cases with dysmenorrhœa due to obstruction is very small. Some women suffer with dysmenorrhœa until they are married and bear chil-

dren, but never after; in others this is not the case.

It is important to inquire what the pain is like. There are two forms of dysmenorrhœa: one is referable to the state of the uterus at the time; the other belongs to the ovaries, it is ovarian in its origin, and requires attention to them for its cure. We must recollect that menstruation involves two processes,—first, rupture of a Graafian follicle, and, secondly, rupture of the capillaries in the uterine mucous membrane,—one ovarian, the other uterine. Where the pain decidedly precedes the flow, it is ovarian; where it continues during the flow, it is uterine.

Every year he sees cases of young girls who come from the country to school in New York City to finish their studies. After three or four months they suffer with dysmenorrhœa, and the flow is scanty. Here the pain usually precedes the discharge, showing the effect of lowered vitality upon the ovaries.

In the treatment he most frequently employs lactate of iron (gr. iii-v, s. t. d.), generally associated with chlorate of potassium, which exerts a special effect upon the pelvic organs, commencing this about ten or twelve days before the menstrual period. The time to give it is when the patient shows symptoms of constitutional disturbance: she is irritable, nervous, languid, over-sensitive, has pain in the eyes, etc. In the interval he gives apiol, two capsules after each meal, which he regards as almost a specific. Where the patient has strong vitality, is robust, and shows too much ovarian excitement, he gives bromide of sodium between the principal meals and at bedtime. This class of cases is one which includes young widows, patients who never suffered from uterine trouble before or during marriage, but exhibit great ovarian excitement afterwards. Nothing can be found to explain it upon vaginal examination. The sodium bromide he prefers to the potassium salt, as it is less likely to cause an eruption upon the face, a matter of some moment to young women.

SECOND DAY.—*Morning Session.*

Gilman Kimball, M.D., of Lowell, Mass., delivered the annual address of the President, taking for his topic a *Biographical Sketch of Dr. Nathan Smith, of Vermont, the Founder of Dartmouth Medical College*. He paid a generous tribute to the personal worth and professional attainments of Dr. Smith, who, in July, 1821, performed the second successful case of ovariectomy that had ever been done in this country. As he was not aware that McDowell had preceded him in the operation, it was entirely original with him, and in point of merit he stands equal to McDowell, and should have equal honors.

Prof. Gross, being invited to make some remarks, said that, nearly thirteen years hav-

ing elapsed between the operation of McDowell and that of Smith, the latter operator had abundant time to have learned of the former operation, and should have known of it, as an account had been published in 1816. He thought that one of the greatest of Dr. Smith's achievements was the bringing into the world of Dr. Nathan R. Smith, of Baltimore.

Dr. Kimball explained that intercourse between the East and the West was difficult and slow at the period to which he had referred, and it was possible that Dr. Smith knew nothing of the earlier operation, and the speaker fully believed that he did know nothing of it.

A Rare Form of Abdominal Tumor.

Dr. Thad. A. Reamy described three cases of a rare form of abdominal tumor. Upon examination they were discovered to be cystic, containing bloody fluid in two cases; the other case died, and at the post-mortem sarcoma of the omentum was discovered. This raised the question whether or not the other cases, which now enjoy good health, would have become sarcomatous if not tapped, or whether the other one had degenerated into a sarcoma. He presented the specimens taken from this patient, from which it would appear that it had been originally a cyst of the omentum, in the walls of which sarcomatous tumors had developed. The patient had died from rupture of this cyst into the peritoneal cavity, causing peritonitis.

DISCUSSION.

Dr. Sutton, of Pittsburg, concurred in the statement of the rarity of these tumors. He did not think it possible before the abdomen is opened to decide whether an omental tumor is carcinoma or sarcoma. He considered it bad treatment to plunge a trocar into the collection, and advocated abdominal section, but thought there was little hope of prolonging the life of the patient if the growth be either carcinoma or sarcoma: one is as malignant as the other. He believed that when the exploratory incision reveals a malignant growth the abdomen should be closed and the operation abandoned.

Dr. Campbell said that as omental growths are usually pedunculated he thought it worth the risk to remove such tumors after the exploratory incision had been made and there were no extensive adhesions.

Dr. Reamy, in closing, said that he could not quite agree with Dr. Sutton as to the impropriety of tapping, and called attention to the fact that the two which were tapped recovered. He said it was a curious fact that in the patient with the sarcomatous growth no cachexia was present; the other two cases could not have been sarcomatous, because they recovered.

*Congenital Fissure of the Female Urethra,
with Exstrophy of the Bladder.*

Henry F. Campbell, M.D., of Augusta, Georgia, presented a paper in which he described a case of congenital fissure of the urethra in a little girl two years of age, with exstrophy of the bladder, which appeared as a vascular tumor in front of the urethra. The upper wall of the urethra presented a flattened appearance; there was but very little trace of a lateral border. The other portions of the vulva were normal, and there was no deficiency in the pubic bones. He regarded the case as analogous to the condition of hypospadias in the male. He inquired as to the proper time for operation, and whether it would not be better to wait for the development of the parts at puberty. He feared that an immediate operation might interfere with the development of the parts, by removing portions of tissue which were susceptible of development.

Dr. B. B. Brown, of Baltimore, described a similar case, complicated by the presence of a stone in the ureter. The child died before operation.

*A Study of the Etiology of Perineal Laceration,
with a New Method for its Proper Repair.*

T. A. Emmet, M.D., of New York, after referring to the fact that he had devoted considerable attention for a number of years to the subject of perineal laceration, said that he was convinced that its effects had been much overestimated. The suffering ascribed to laceration of the perineum is not proportionate to the extent of the lesion, and some of the severest cases are entirely unaccompanied by symptoms. He directed special attention to the anatomy of the pelvic fascia, showing its attachment to the pelvic organs and to the inlet of the pelvis, and declared that these organs are held in place by this fascia, which is continued downward as a sheath for the vagina. During labor this fascia may be injured or lacerated: when this condition occurs, perineal laceration often follows in the descent of the head and shoulders of a child. Even in cases without external laceration, relaxation of the vagina occurs, and the posterior wall falls away from the anterior one. This rolling out of the mouth of the vagina, as if the drawing-string had been broken, exaggerates the appearance of laceration of the perineum, making it seem more extensive and important than it really is. The operation which he proposed had for its object the shortening of the posterior wall of the vagina, so as to restore to it its relation to the anterior wall. This object is attained by making two crescentic lines of denudation transversely across the vagina, and uniting them by a line of sutures which after the operation are hidden entirely within the vagina. The result is that the perineum is drawn up-

ward towards the pubes, and any laceration existing in it may be disregarded, or it may be united by an interrupted suture. He maintained that we might leave out of consideration, in performing the operation, everything in regard to the external organs outside the line of hymen. His object was to call special attention to the rôle which the fascia plays in supporting the pelvic organs, and to the fact that the lacerated perineum has little or nothing to do with the symptoms complained of.

Afternoon Session.

Dr. Emmet gave a résumé of his paper read at the morning session.

Dr. Reamy said the operation described seemed an admirable one for a particular class of cases, the number of which he believed to be limited. He did not regard it as a substitute for the operation for lacerated perineum.

Dr. F. P. Foster fully endorsed the statements of Dr. Emmet with regard to the function of the perineum, and denied that it had anything whatever to do with supporting the uterus under ordinary circumstances.

Dr. Sutton said that he had understood Dr. Emmet to deny the existence of the perineal body. He could not believe that he meant to say that there is no such body existing between the rectum and the vagina, which is shown in frozen sections. He believed that the uterus was supported by all the surrounding structures.

Dr. Emmet, in closing the discussion, said that he would not deny the existence of the perineum, but would deny the existence of a body anything like that which operators had attempted to build up, called the perineal body. He thought the members would understand his operation better when they had an opportunity of reading the paper.

*The Management of Accidental Puncture and
other Injuries of the Gravid Uterus as a
Complication of Laparotomy.*

C. C. Lee, M.D., of New York, called attention to this grave complication of laparotomy, and gave the details of seven cases, all he could find in medical literature, including one that had occurred in his own practice. From them he deduced the following conclusions:

First.—The pregnant womb may be punctured or otherwise wounded during laparotomy without necessarily causing abortion.

Second.—Both from a *priori* and clinical evidence miscarriage seems to depend upon injury of the uterine contents, not of the womb itself, however severe.

Third.—If the former has certainly occurred, Cæsarean section is indicated and should be promptly performed. In this case the utmost care must be subsequently taken to secure thorough drainage from the uterine cavity.

Fourth.—If the uterine walls alone are injured, the wound is to be treated on general principles. If a deep puncture or incision, it must be sutured with the minutest care, with exact coaptation of the edges. For this purpose fine silk sutures, rendered antiseptic, are the best. If a nick or superficial puncture, it must not be ligated, for ligatures cut quickly through uterine tissue; if too small to be sutured, the bleeding points must be lightly touched with the thermo-cautery until oozing has ceased. Good surgery and the dictates of humanity alike demand that under such circumstances a chance of survival be given the child as well as the mother.

DISCUSSION.

Dr. Byford, of Chicago, said that before hearing this paper he had concluded that it would always be proper when the uterus had been accidentally wounded in laparotomy to open the organ and remove its contents, but after hearing Dr. Lee's case he believed there might be exceptions to this rule, especially in the early stages of pregnancy; in the later months the traction of the muscular fibres is so great that he felt sure the stitches would tear out. In such a case he should be inclined to remove the contents of the uterus, even if the wound had not involved its whole thickness.

Remarks were also made by Dr. Wilson, of Baltimore, Dr. Garrigues, of New York, and by Dr. Lee in conclusion.

Is Extirpation of the Cancerous Uterus a Justifiable Operation?

A. Reeves Jackson, M.D., of Chicago, said that he proposed to discuss this question: In view of known facts, is it justifiable to extirpate the uterus for carcinomatous disease? Reviewing the history and the statistics of the operation, he concluded that extirpation of the uterus for cancer does not prolong but destroys life. By the abdominal operation there was a mortality of 72.5 per cent; by the vaginal operation, 28 per cent. His conclusions are as follows:

I. Diagnosis of uterine cancer cannot be made sufficiently early to insure its complete removal by extirpation of the organ.

II. When the diagnosis can be established, there is no reasonable hope of effecting a radical cure, and other methods of treatment offer far less danger than excision of the entire organ, and are equally effectual in the amelioration of suffering, in retarding the progress of the disease, and in prolonging life.

III. Extirpation of the cancerous uterus is a highly dangerous operation, and neither lessens suffering, except in those whom it kills, nor gives a reasonable hope of a cure in those who recover. Hence, as it is lacking in all the essentials of a beneficial operative procedure, it should be excluded from modern surgery.

DISCUSSION.

Dr. Van de Warker, of Syracuse, endorsed the statements just made, and described his treatment of progressive destruction and sloughing of the uterus by chloride of zinc. He had operated on eight cases, three of which had died.

Dr. Emmet approved the sentiments of the paper, and reported one unsuccessful case. If the operation is ever done, it should be by the vagina, and should be restricted to removing the uterus for sarcoma.

Dr. Baker, of Boston, opposed the conclusions of the lecturer, and said that he had operated on at least thirty cases by the vaginal method, and he could recall six cases of at least five years' standing which have absolutely recovered. The cases in which total extirpation is advisable are extremely rare, and comprise only those which begin in the fundus of the uterus.

Dr. Palmer, of Cincinnati, said that the operation in some cases is clearly unjustifiable. In others it may be justifiable. In the latter he would include only those cases of sarcoma starting in the uterine body, as it is usually impossible to determine whether the disease has already extended beyond the uterus or not. He made it a rule to decline to operate.

Dr. Sutton said that removal of the uterus by the vagina is not as fatal as ordinary ovariectomy. Schroeder's mortality was only one in thirteen. He then described the details of his vaginal operation for the removal of the uterus. The opening in the vault of the vagina is not sewed up after the operation, but a large drainage-tube is passed through the vagina into the peritoneal cavity, and the vagina packed with cotton and iodoform. This drainage-tube is not used by Martin, who simply uses the antiseptic tampon.

Dr. Jackson closed the discussion by reaffirming his conclusions.

A paper entitled *A New Method of Operating for Fistula in Ano*, by Edward W. Jenks, M.D., of Chicago, was read by title.

THIRD DAY.—Morning Session.

The first paper read was one entitled

Menstruation after Extirpation of the Ovaries,

by Henry F. Campbell, M.D., of Augusta, Georgia. Dr. Campbell said that he would not question the influence of the ovaries over the function of normal menstruation; but cases have occurred in which menstruation persisted after their removal. This return of menstruation after double ovariectomy has been attributed to habit, to plethora, and more recently to the fact that in removing the ovaries there had not been taken away the portion which is the real inciter to the menstrual nixus,—the Fallopian tubes. With-

out denying any of these propositions, he wished to advance an explanation which had not been hitherto noticed, or, at least, given its full value. On account of the prominent position occupied by the ovaries in the female genital apparatus, it might be reasonably anticipated that their removal might have some influence upon the function of menstruation,—that it might cease. We know the influence that the mammary gland exerts upon menstruation, and that mental emotions also influence this process. It is true that this is in the presence of the ovaries; but in the absence of these organs can we call into existence anything which might explain the influence of these remote inciter points upon the congestion of the uterus and menstruation? for it is possible from the influence upon the uterus of these inciters to menstruation, that even after removal of the ovaries the menstrual discharge might continue. He cited a case of a young girl seven to eight years old, in whom menstruation followed the mumps, from metastasis to the ovaries. The menstrual discharge occurred for several months, and then gradually subsided. She changed naturally at the age of fifteen. In another child menstruation appeared temporarily as a result of an abscess of the mammary gland: the menstrual nixus afterwards disappeared, to return normally at the physiological period. He could only explain these cases on the supposition of a communication through the nervous system, and for certain reasons he located in the lumbar region of the spinal cord a nervous centre controlling ovulation and periodical uterine congestion. He mentioned a case of amenorrhœa and sterility which was cured by putting a child to her breast to nurse; and another where a grandmother from putting a child to the breast began to secrete milk, and nursed the child for months. The fact that a man can feel pains in his foot and toes after amputation of the leg was cited to prove that the centre in the spinal cord may remain active even after it is cut off from the organ to which it belongs.

The object of Battey's operation is to nullify sexuality; but it does not do so entirely; it might if performed before development had taken place, but after the organs have undergone periodical congestion for years the centre is normally developed, and, accustomed to respond to the irritation of healthy or diseased ovaries, may continue its action upon the uterus even after the ovaries themselves have been removed. That is to say, through the action of the nervous centre, probably situated in the lumbar enlargement of the spinal cord, the uterus may continue its function of menstruation even after the removal of the normal inciters to menstruation, which he admitted to be the ovaries.

DISCUSSION.

Dr. William Goodell said that the return of

menstrual periods after oöphorectomy is not a common occurrence, but in the cases in which it was present this might be the probable explanation. He had noticed a sanguinolent discharge on the third or fourth day after removal of the ovaries, which he attributed to the irritation of the ligature.

He mentioned a case which had a bloody discharge coming on several months after oöphorectomy, and he found it due to sarcoma of the uterus. Where menstrual discharges regularly occur it is possible that there is a third ovary present, as suggested by Koeberle. Another explanation is that possibly some of the ovarian stroma had been left behind, as it is difficult in some cases with adhesions to separate the ovary entirely without tearing. He thought that the paper should have contained some statistics.

Dr. Emmet reported a case of double ovariectomy where he had also removed both Fallopian tubes. The patient since then has menstruated thirteen times. The only difference noticed was that her periods were not quite so long as they were previously.

Dr. Garrigues mentioned a case of a young woman who after removal of both ovaries married and had a child. Here there must have been a third ovary present.

Dr. Thomas said that Dr. Campbell's explanation might be possible in some cases; he was not prepared to deny or to accept it. With regard to the frequency of menstruation after operations, he said that he had performed double ovariectomy in fifty or sixty cases, and the impression upon his mind was this: where the ovaries are present, menstruation is the rule; where they have been removed, menstruation is the exception. After their removal the uterus may pass through some periods of congestion and metrostaxis, on the same principle as a sturgeon's heart will beat after removal from its body,—by a sort of registering action, as Professor Draper called it. He had performed both Battey's and Tait's operation, and believed the latter less likely to be followed by this spurious menstruation, since it removes more tissue. He referred to an operation in which he removed two diseased ovaries, and found a third normal, which he allowed to remain. He does not believe that the Fallopian tubes have anything to do with inciting to menstruation: he therefore had adopted the rule to remove the ovaries if they are diseased, but not to remove the Fallopian tubes unless they also are diseased.

Dr. Byford said that in giving an explanation of the persistence of menstruation after ovariectomy, very much depends upon what is called menstruation. If ovulation is menstruation, then menstruation can occur only when ovarian stroma is present; if a bloody discharge from the uterus is menstruation, it may occur, under certain circumstances, after the ovaries have been removed.

Dr. Mann mentioned disease of the uterus among causes of spurious menstruation after double ovariectomy: in one he had found cancer of the cervix.

Dr. Campbell said that he had examined bodies for forty years, and never saw a supplementary ovary, but did not deny its possibility. He said that habit does not explain anything except nervous action: the surgeon's heart beats after removal on account of its contained ganglia. He had not denied that the ovaries are the natural inciters to menstruation, but he had endeavored to pursue the subject a little deeper in order to show how they bring it about.

Remarks on Chronic Abscess of the Pelvis.

W. H. Byford, M.D., of Chicago, read a paper in which he discussed the pathology and treatment of certain forms of chronic abscess within the pelvis. He traced them from a bloody effusion, generally after confinement, the hæmatocele becoming purulent, and subsequently either discharging or being formed into a solid fibroid mass by absorption of its fluid contents. In old abscesses he had found tag-like processes depending from the interior of the cyst, which is lined by hyogenic membrane, and he advocated their removal by the curette after evacuating the cyst. With regard to method of opening, he advocated free opening into the vagina, and the use of antiseptic washes. The aspirator needle may be inserted into the abscess, and a bistoury run along it as a guide, an opening being made large enough to admit three or four fingers. He looked upon the interior of the abscess as being similar in structure to the surface of an external ulcer, as it may have healthy or flabby and fungoid granulations, and may give rise to healthy or unhealthy pus. In the course of time the granulations become converted into cicatricial tissue. He referred to several cases illustrating the principles of treatment.

DISCUSSION.

Dr. Thomas thought that the author of the paper had rendered a good service in studying the changes in the lining membrane. There is one important point about opening these abscesses. Some years ago Dr. Brittain, of New Orleans, recommended the trocar in seeking after the pus. Dr. Mundé still more recently advocated the aspirator; Dr. Lyman has recommended the same. In his own opinion, there is no more dangerous practice in gynecology than to seek for these abscesses, when they are located high up, with the trocar or aspirator: this should only be done after the diagnosis has been made by manipulation and other means. He had employed the aspirator himself in diagnosis, but not as a method of treatment, and thought it a very bad method. The opening should be a free one. In order to keep the opening

from contracting, he had a glass tube with a flange made to insert into the opening, so that he could use daily injections of carbolic acid and iodine.

He mentioned a class of cases where the pelvis seems filled with an abscess, the uterus is immovable, and the tissues are hard as a board. In these he had adopted the method of Tait in making an incision along Poupart's ligament into the abscess and cleaning it out and using frequent injections. With reference to the curette, he had had no experience with it in these cases.

Dr. Goodell was pleased with the paper and recommendations of Dr. Byford as to the curette. He preferred permanganate of potassium for the injections. He did not regard the aspirator as being so dangerous as the last speaker did: he had used it with great relief when the pus was situated high up. He had also performed Tait's operation, carrying a drainage-tube through into the vagina.

Dr. Thomas, in reply to a question about the performance of the operation in a case in a state of great prostration, said the operation was a desperate one, but the patient's case is even more desperate: it might offer the only chance of recovery.

Dr. Sutton saw Esmarch, of Kiel, scrape out abscesses in all parts of the body, and thought it the accepted treatment abroad.

Dr. Campbell said that he was not familiar with the practice of curetting abscesses, but after evacuation he sometimes packed them with linen, in order to encourage granulation. He urged the importance of constitutional measures, and particularly of the tartrate of iron. For injections he preferred Labarraque's solution.

Dr. Byford, in closing, said that he had not presented anything like a complete treatise on pelvic abscess, but had simply tried to call attention to one form, and to bring its treatment before the Society for discussion. In the cases mentioned by Dr. Thomas he had several times carried out the treatment mentioned, by carrying a drainage-tube into the vagina.

Ergot; the Use and Abuse of this Dangerous Drug.

George J. Engelmann, M.D., of St. Louis, made some remarks upon ergot, calling attention to its powerful action, and to the danger of its abuse by nurses, midwives, and the public generally. He said that he never had any real use for this drug; its action can never be relied upon with certainty. The only condition in which it might be of use is in post-partum hemorrhage, and here we have safer and more efficient remedies. He would like to see the use of ergot restricted to the non-pregnant womb. There are no circumstances in which it is necessary to give it, and few in which it is desirable to give it in this condition. It is only in the third stage of labor that the constant contraction of the uterus is

NORMAL LIQUIDS.

WE HAVE placed before the medical profession, under the name of "NORMAL LIQUIDS," a class of preparations for which we believe there has long been a demand. Normal Liquids are, essentially, fluid extracts, but they differ from these preparations as manufactured after the formula prescribed by the "Pharmacopœia," in that they are of definite and uniform strength, and not dependent for their activity on the strength of the drugs from which they are prepared. The physical condition of a drug is no criterion of its alkaloidal strength, and as this condition is usually the sole guide in the selection of the drugs from which fluid extracts are prepared, it follows that there must be great variability in the strength of such preparations manufactured from different lots of drugs. In the manufacture of Normal Liquids the crude drug is assayed previous to maceration, and its precise strength determined. Should this strength not be sufficient to bring the strength of the finished fluid up to the standard adopted for it, the quantity of the crude drug is sufficiently increased to secure it, as determined by another assay of the finished preparation. By this method Normal Liquids are as definite and uniform in their strength as morphina, quinina, or other alkaloids.

We were induced to prepare Normal Liquids through the favorable reception of our *Liquor Ergotæ Purificatus*, which is prepared after the manner above indicated. Our list of these preparations is as yet limited to the following, but it is our design to increase it until it shall embrace all drugs containing alkaloidal principles:

Liquid Aconite, Normal.

Liquid American Hellebore, Normal.

Liquid Belladonna Leaves, Normal.

Liquid Belladonna Root, Normal.

Liquid Cannabis Indica, Normal.

Liquid Cinchona Calisaya, Normal.

Liquid Cinchona Red, Normal.

Liquid Colchicum Root, Normal.

Liquid Colchicum Seed, Normal.

Liquid Conium Seed, Normal.

Liquid Ergot, Normal.

Liquid Foxglove, Normal.

Liquid Gelsemium, Normal.

Liquid Henbane, Normal.

Liquid Ipecac., Normal.

Liquid Mandrake, Normal.

Liquid Nux Vomica, Normal.

Liquid Rhubarb, Normal.

Liquid Stramonium Leaves, Normal.

Liquid Stramonium Seed, Normal.

We bespeak for our Normal Liquids the cordial indorsement of all who subject them to either physiological or therapeutical tests. They are a further move in the direction of definite therapeutics, and as such they will commend themselves to progressive physicians.

DETROIT, MICHIGAN.

BOUDAULT'S PEPSINE.

The only Pepsine used in the Hospitals of Paris for the last 30 years.

Unlike the various substitutes which, in some cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be almost useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 1872, 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy every one that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

With a view of bringing this important remedy within the reach of all, the price has been materially reduced. It is now not only the best, but comparatively the cheapest.

In answer to frequent calls, another preparation is now offered,

BOUDAULT'S SACCHARATED PEPSINE,

having the same high digestive power as the amylaceous; it will be sent only when specified.

Boudault's Pepsine is sold in bottles of 1 ounce, with a measure containing exactly 5 grains; also in bottles of 4, 8, and 16 ounces for dispensing.

Boudault's Saccharated Pepsine is sold in bottles of 1, 4, 8, and 16 ounces for dispensing.

Besides Boudault's Pepsine in powder, we offer also

BOUDAULT'S WINE OF PEPSINE.

In this preparation the taste of Pepsine being perfectly disguised, it may be recommended to persons who have difficulty in taking Pepsine in the form of powder.

DR. RABUTEAU'S

(Laureate of the Institut of France)

DRAGEES, ELIXIR, AND SYRUP OF IRON.

"The experiments made in the hospitals of Paris have demonstrated that *Dr. Rabuteau's Dragees, Elixir, and Syrup* regenerate the red globules of the blood with a rapidity never observed with the use of the other ferruginous preparations. These results have been proved by the various *Compt-Globules*.

"The ferruginous preparations of *Dr. Rabuteau* do not cause any constipation, and are perfectly tolerated by the weakest persons."—*Gazette des Hôpitaux*.

Dr. Rabuteau's Elixir is prescribed when some difficulty is experienced in swallowing the Dragees; it is especially adapted to weak persons whose digestive functions need strengthening or stimulating.

Dr. Rabuteau's Syrup is especially prepared for children, who take it readily because of its agreeable taste.

A sample of Rabuteau's Dragees will be sent free to any physician mentioning THE MEDICAL TIMES.

Prepared by CLIN & CO., Pharmacists, Paris. E. FOUGERA & CO., Agents for the United States.

TANRET'S PELLETIERINE

FOR THE TREATMENT OF TAPE-WORM (TÆNIA SOLIUM).

This New Tæniacuge, the active alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker, Beaujon, etc., have all been most satisfactory. Dr. Dujardin-Beaumetz, Member of the Academy of Medicine, and Prof. Laboulbène, in their report to the Society of Therapeutics, have given it their unqualified approval after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured. Pelletierine is prepared by

M. CHAS. TANRET, Pharmacien de 1re Classe, 64, Rue Basse du Rempart, Paris.

DUCRO'S ALIMENTARY ELIXIR,

A COMBINATION UNITING THE PROPERTIES OF

ALCOHOLIC STIMULANTS AND RAW MEAT.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring the administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonary Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE., Paris.

Agents for the United States, E. FOUGERA & CO., NEW YORK.

desirable; but even here damage may be done by the use of ergot: the placenta may be incarcerated, and he would never advise its use till the uterus is emptied. Some of the dangers of its use are ruptures of the uterus, lacerations of the cervix, vagina, or perineum, besides possible injuries to the child. The worst feature of it is that the injuries produced by it are usually not noticed at the time; and the physician who gives it is generally in ignorance of the damage that is done, which is only discovered long after by the consultant, who may learn, perhaps only by accident, that ergot has been used.

DISCUSSION.

Dr. Johnson said that he had read a paper on this same subject last winter, condemning the use of ergot in parturition; but in the discussion Dr. Barker had directed attention to the fact that it might be useful in cases of threatened hemorrhage where chloroform has been given. He did not agree with the author of this paper as to the reckless use of it by the profession. He did not know that any intelligent physician would give it before the last stage of labor.

Dr. Campbell said that in 1836 or 1837 Dr. Milton Anthony, a Southern physician, had written some stringent articles upon the use of ergot in labor, limiting its use, and advising that it should never be given before full dilatation of the os, and rarely before the expulsion of the child. He said this had been his own practice: he would never give it for post-partum hemorrhage, but in order to prevent post-partum hemorrhage.

Dr. A. H. Smith thought ergot in the hands of the general practitioner an unmitigated evil. It is always calculated to do harm, and often does harm. He thought the tetanic contraction produced by ergot was unnatural and undesirable. The contractions of the uterus should be intermittent: therefore every one who gives ergot to produce expulsion of the contents of the uterus violates nature. In the early stage of labor it may produce rupture of the uterus, and in the later stage it is unnecessary. In conclusion, he denied that chloroform produces relaxation of the uterus or predisposes to post-partum hemorrhage.

Dr. Campbell said that he had never given ether in a case of labor in his life; he had always used chloroform; but he still thought it disposed a little towards the relaxation of the uterus.

Dr. Ellwood Wilson said that he had used chloroform for years in his practice, but had been obliged to give it up on account of its tendency to produce post-partum hemorrhage without any particular relaxation of the uterus. He had seen the same from the long-continued use of ether. He had been surprised to hear that ergot should be abolished. He believed that no man should approach a case of placenta prævia without ergot. In thirty-

two cases in his own practice he had used it in order to obtain the very tonic contraction which it had been claimed it exerts. He had also been surprised to hear that it had no value in post-partum hemorrhage. He considered it of immense value in post-partum hemorrhage. The difficulty usually is that ergot is given too late and in too large quantities. He said that in cases of long-delayed labor followed by hemorrhage, after its administration the patient usually called attention to a feeling of heat, at the same time the uterus contracts and the bleeding ceases. He regarded this as a very important use of ergot. A dose of half a teaspoonful of the fluid extract will produce its impression in about ten minutes, and after the expulsion of the placenta will produce tonic contraction of the uterus. He said he thought it bad practice to throw water, carbolized or non-carbolized, into the recently-delivered uterus. As regards the use of ergot after abortion, he had been thus employing it all his lifetime, and had never experienced any great difficulty in treatment except in one case which he had unfortunately tamponed. The next day she had peritonitis, and died in thirty-six hours.

Dr. Engelmann feared that he had been misunderstood. He had not meant to discuss the limits of the possible use of ergot when used in scientific medicine and in skilful hands, but to assert his belief founded on experience that it is a dangerous drug and does a great deal of mischief as commonly employed. It is a great factor in producing uterine disease. He did not think it necessary even in post-partum hemorrhage, because there are better and safer means of treatment, and these means should be more generally employed.

A paper entitled *A Theory to Explain the Relaxation of the Vagina and Perineum during Labor*, by Dr. James R. Chadwick, of Boston, was read by title, Dr. Chadwick having been called away.

The hour for adjournment having arrived, the programme was declared closed.

Dr. William Goodell offered a series of complimentary resolutions to Dr. Chadwick, the former Secretary and founder of the Society, which were unanimously adopted.

On motion, similar resolutions were adopted with regard to Dr. Mundé, who had been for several years the Treasurer of the Society.

The newly-elected President, Dr. Albert H. Smith, upon taking his seat returned thanks for the honor conferred, and, on motion, the Society was adjourned.

OFFICERS FOR THE ENSUING YEAR.

President.—Albert H. Smith, Philadelphia.

Vice-Presidents.—James R. Chadwick, Boston; Samuel C. Busey, Washington.

Secretary.—Frank P. Foster, New York.

Treasurer.—Matthew D. Mann, Buffalo.

Members of Council.—T. G. Thomas, For-

dyce Barker, New York; T. A. Reamy, Cincinnati; R. S. Sutton, Pittsburg; R. B. Maury, Memphis.

The Society then adjourned, to meet on the third Tuesday of September, 1884, in Chicago, Ill.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

At a conversational meeting held at the hall of the College of Physicians, Philadelphia, September 12, 1883, the President, Dr. Wm. M. Welch, in the chair, Dr. Chas. M. Seltzer read a paper on "Dietetics for the Sick" (see page 5).

DISCUSSION ON DIETETICS FOR THE SICK.

Dr. L. Turnbull, in opening the discussion, said: In reference to these questions my opinions are rather of the old-fashioned kind, and I believe that courses of instruction on cooking will be of much use to physicians. Dr. Benj. Rush was accustomed in his lectures to remark that "a physician should spend six months in a kitchen before entering upon his practical career." He desired to heighten the importance of a knowledge of the effects of food, and also the correct way of preparing it. All these advantages could be combined with a course on pharmacy. Physicians should learn how to make beef-tea, extract, etc., and similar articles. The important preparations of mush, of Indian and oat meal, for instance, are rarely properly made. They should be prepared over-night, so as to be thoroughly gelatinized; if made in the morning just before being served, they will not be digestible. In cases of very weak stomachs, many articles of diet may be peptonized with great benefit by using a small amount of a mixture of sodium carbonate and pancreatin, these being allowed to act for a short time at a temperature of about 80° F. Fairchild, of New York, prepares powders containing these peptonized materials in convenient amount. Such peptonized foods are like the old-fashioned preparations made with rennet and warm milk, and will be well borne by delicate stomachs. An article that is often wrongly prepared is barley. It may be softened and extracted with water, or it may be torrefied so as to make a sort of malt extract. In the latter form it is very suitable as a substitute for the diastase-like principle of the saliva in cases where that secretion is deficient. It can easily be given mixed with other food, as in puddings, for instance.

This summer we have been very successful in relieving the irritability of the stomach and bowels of both children and adults, due to temporary indigestion, by substituting first barley-water alone, and after a time a wineglassful of barley-water, with half a tumbler of milk, or its equivalent of condensed milk.

Too little attention is given to character of water. It is sometimes very bad, containing either injurious mineral or vegetable matter. The Boston water-supply was much injured lately by certain sponge forms.

Butter is an article of food which is often impure, and, besides, objectionable substitutes for it are often sold. The mixtures of animal fats known under the names of oleomargarine and butterine should not be used in the preparation of food.

Beef-tea contains often but little nourishment, and in debilitated conditions, such as most cases of typhoid fever, beef-essence, made, not from the round of beef, but from the neck, in which blood is found, will be much more nourishing. A valuable form of beef-juice can be prepared by cutting up in pieces fresh beef and placing it under a block of ice until, by the pressure, all the blood has been extracted. With the addition of a little salt it has been found to be retained by the most delicate stomach, and is very useful in cases of great exhaustion.

Dr. Albert H. Smith said: The older we get, the less disposed we are to rely on medicine and the more on diet. The remarks in the paper in reference to the importance of teaching physicians the art of cooking are deserving of full endorsement. On one point, however, I cannot agree with the author of the paper. He seemed to advocate the use of highly-stimulating food in acute diseases; in other words, the methods advocated by Dr. Thos. King Chambers in his fascinating work,—a work, however, which has done great injury. Dr. Chambers's idea was that all disease was due to depression, and therefore the remedy was to stimulate the system. This is an attractive theory, but is not true. In cases of disease attended with high temperature, we only add fuel to the flame by the use of stimulating food.

Nature has admirable powers of taking care of herself, even under a starvation regimen. The use of a low form of diet, with refrigerants and depressants, may often be of the greatest benefit. I can look back on my early experience, and recall cases in which, after operative measures, patients have been treated on the theory that plenty of pabulum should be furnished in the system, but such patients have perished. A strong patient will in such cases do much better on a low diet. Adhesive inflammation will be secured more satisfactorily on the low-diet system.

Dr. J. M. Barton: I had under my charge during three years a patient who sustained life on about a pint of milk a day,—never more than a quart a day. He was a physician, who had his own views on questions of diet and therapeutics. Dr. A. H. Smith is right in his position as to the importance of low diet after operations, but in typhoid fever we have a very different indication. In the first case—*i.e.*, after operations—food frequently acts as

an irritant, but in the low fevers the patient is exhausted and needs support.

Dr. Forbes: I am reminded of a compliment which I heard the younger Larrey pay to Orfila, the great French chemist. He said that he (Orfila) was the greatest cook that ever lived. He said Orfila understood the disintegrating power of hot water. The effect of thorough boiling is most important, and since the days of Washington it has been an article of war that beans should be boiled for six hours. In the Crimea, marked difference was seen between the French and English troops on account of the superior attainments of the French officers and surgeons in reference to many of the details of a soldier's life, and especially in cooking.

Dr. Seltzer, in closing the discussion, said: I did not wish to include in the paper a discussion of the methods of preparing food, but merely to express the idea that it is important that doctors should know what to cook and how to cook. Many articles of food that as ordinarily prepared are unfit for the sick can be cooked so as to be palatable and digestible. Mrs. Rorer's method of cooking liver is an instance of this. She exhausts it with water to remove blood, then places it on ice until required, when it is cut into thin slices and toasted: sweetbreads are somewhat similarly prepared.

As to the use of stimulating food, we must judge Dr. Chambers's views by his own method. He draws the line between acute and chronic diseases, not making time the basis of the classification, but the tendency of the disease. Acute diseases tend to recovery, and these he leaves undisturbed; chronic diseases tend to fatal results, and in these he uses a highly nutritious diet, stimulating when a depressed state exists.

In reference to the suggestions made by different speakers as to the importance of systematic instruction of physicians in the art of cookery, I may say that such courses are now being organized. I do not think that such instruction can be advantageously given with pharmaceutical teaching. A woman's taste and tact are essential to the art.

Dr. Henry Leaman then read a paper on a "Case of Amputation of the Breast, with Remarks" (see page 8).

DISCUSSION ON AMPUTATION OF BREAST.

Dr. Baldwin: I remember that the late Dr. Atlee spoke of the effects of arsenic in carcinoma and gave a number of cases in which he used it with the apparent effect of preventing the return of the tumor. I employed it in a case on which operation was performed in 1875, the patient being put on the use of Fowler's solution, continued until 1876, when the growth redeveloped and a second operation was done in 1878; no return has occurred to this time. The use of arsenic was discontinued after the second operation. During

the formation of the second growth some trouble occurred in the lung, and cancer of that organ was feared, but it disappeared after operation.

Dr. Forbes: Dr. Leaman speaks of a period of efflorescence after operation, by which I understand a general development in different organs; this, as he remarks, does not always occur after first operation. In 1864 I removed a cancer from the breast of a lady. In 1867 a hardened growth appeared in the cicatrix. It was not removed at once, as it was then giving no pain. In a short time, pain having developed, it was removed. It returned a number of times, and was each time removed until it developed in attachment to the interosseous cartilage and the muscles, and then I declined to remove it, although the patient very much urged me to do so. It continued to increase, and in eighteen months it involved the integument on the clavicle and sternum. Its condition was much aggravated by various caustic applications. Finally, some irregular parties attempted to remove parts of the diseased mass, and this was followed by an efflorescence, and a number of organs in the thorax and abdomen became involved. The patient died eighteen months after the last attempted operation.

I have heard Dr. Geo. W. Norris speak of this condition of efflorescence and its likelihood to occur in patients upon whom the cauterizing and escharotic treatment had been practised. After such treatment he advised non-interference with the knife.

Dr. J. M. Barton: I have been interested in examining the advertisements and circulars of the empirics who claim to cure cancer without operating, and I find them reporting cures of cases of over forty years' duration. Now, as scirrhus if left untreated does not usually last more than four years, it must be that these long cases are benign tumors.

Even when the knife does not cure, it may prolong life,—make it more tolerable. Operation offers us ten per cent. of recoveries. Dr. Leaman's case can be regarded as typical. The almost immediate return in the axilla is suggestive of the possibility that some affected gland had escaped removal. The removal of the entire breast in the earlier stages gives chance of total recovery, and in the later stages, with ulceration, operation is also useful; but in the intermediate periods, when the tumor is extensive and adherent to the adjacent structures, non-interference is best.

Dr. Albert H. Smith: I am glad to hear Dr. Barton advocate the repeated use of the knife; I believe in attacking the tumor every time it appears, for, at the least, life may be prolonged and made comfortable, and the patient may be spared the suffering and loathsome discharges of the advanced stages of the disease, conditions which make her a source of misery to herself and to those around her. Cancer is doubtless a local disease,

although a constitutional taint or tendency is probably inherited. Yet, if the tumor be removed early, a cure can be obtained. Dr. Leaman's patient did not do well because she did not follow the advice he gave at first. Removal of the breast should be complete; every reappearance should be met by operation. I recall the case of a patient from whom, at the first operation, no axillary glands were removed, but at the second twelve were taken out. Two more operations were subsequently performed; at the last one a very large amount of tissue was removed, but perfect union was obtained. Operation should cease when the condition is such that union by the first intention cannot be obtained. In this particular I cannot agree with Dr. Gross, who pays no attention to the size of the cicatrix or to the question of union by first intention. The patient just referred to has been well during this summer, but is not beginning to manifest infiltration, and the condition is such that primary union cannot be obtained, and I do not consider operation permissible. Under the modern advances in antiseptic surgery, operative interference in cases of cancer becomes simple and entails little suffering, and the after-treatment is not difficult.

Dr. Barton: The important point in operation is to make a complete cleaning out of the affected glands, and the obtaining of this must not be interfered with by consideration of the amount of tissue to be removed, or by the desire for primary union. Where much tissue is removed, the after-treatment is more simple than where flaps are made; no counter-openings are needed; no drainage-tubes; no pockets of pus are formed; but little, if any, fever occurs; the wound usually goes on uninterruptedly to full cicatrization. In hospital practice I rarely have to see a case after operation, from which the breast has been thus removed. I cannot recall a case in which the disease returned in the cicatrix so formed, though it often returns in the axilla. I remember a case in which three operations were performed upon secondary axillary growths in a period of four years,—the last operation being amputation of the arm, ligation of the axillary artery, and removal of the growth,—yet the resulting cicatrix from the first thorough breast-operation remained perfectly soft and healthy.

Dr. Leaman: The case I have reported is an ordinary one, and the operation was certainly performed with ordinary care. The axilla was opened, and all present agreed that no glands were affected except the one removed. The first symptoms of return were shooting pains in the fingers, referable to a nodule near the insertion of the sterno-cleido-mastoid muscle, behind the left sterno-clavicular articulation. Subsequently the axillary glands were involved. A few small nodules have since appeared over the seat of the first tumor.

I think it important to remember that surgeons may make mistakes; that some of the cases diagnosed as cancer and apparently cured by operation may be benign tumors.

In my experience arsenic has not been of use in carcinoma.

A NEW USE FOR AN OLD INSTRUMENT.

Dr. Leaman called attention to the fact that he had found the hooked end of Dr. Gross's ear- and nose-instrument the best and safest means of rupturing the membranes in labor.

A communication was also read by Dr. W. R. D. Blackwood, entitled "Remarks on the Chicago Beef Wire Skewer" (see page 9).

The Society then adjourned.

HENRY LEFFMANN, M.D.,
Secretary.

MISCELLANY.

EPIDEMIC RELIGIOUS EXCITEMENT.—The *Journal de Ploërmel* reports a curious example of one of those outbreaks of epidemic nervous disorder which were characteristic of the Middle Ages, but are now rarely heard of. Of fifty pupils of the Girls' Congregational School of Saint Marlo des Trois Fontaines, upwards of thirty-five have been attacked by a nervous disorder having all the symptoms of St. Vitus's dance. The school has been closed by order of the local authorities.

DR. WILLIAM S. JANNEY has been elected Professor of Practical Anatomy and Clinical Surgery in the Medico-Chirurgical College of Philadelphia.

AMERICAN ACADEMY OF MEDICINE.—The annual meeting of the Academy will be held at the New York Academy of Medicine October 9 and 10.

OFFICIAL LIST

OF CHANGES IN THE MEDICAL CORPS OF THE NAVY FROM SEPTEMBER 22 TO SEPTEMBER 29, 1883.

- P. A. Surgeon J. H. BRYAN detached from the U.S. steam-ship "Miantonomoh," and ordered to the Museum of Hygiene, Washington, D.C.
- P. A. Surgeon A. F. MAGRUDER detached from duty at Villefranche, France, and granted six months' leave, with permission to remain abroad during that period.
- P. A. Surgeon C. H. H. HALL to be detached from the U.S. steam-ship "Ranger" on reporting of his relief, and await orders.
- Surgeon J. L. NEILSON detached from the receiving-ship "Franklin," at Norfolk, Virginia, and ordered to the U.S. steam-ship "Ranger."
- Surgeon WILLIAM A. COUVIN ordered to the receiving-ship "Franklin," Norfolk, Virginia.
- P. A. Surgeon ROBERT WHITING detached from the receiving-ship "Wabash," at Boston, and ordered to the Naval Hospital, Norfolk, Virginia.
- Surgeon G. S. BEARDSLEY granted leave of absence for six months, with permission to leave the United States.
- P. A. Surgeon A. A. AUSTIN, orders to Naval Hospital, New York, revoked, and placed on waiting-orders.
- P. A. Surgeon GEORGE C. LIPPINCOTT ordered to the Naval Hospital, New York.
- Medical-Director GEORGE PECK detached from the Naval Hospital, Mare Island, California, and placed on waiting-orders.
- Surgeon D. McMURTRIE and P. A. Surgeon M. H. CRAWFORD ordered to report at Washington, D.C., October 3, for medical survey.

PHILADELPHIA MEDICAL TIMES.

PHILADELPHIA, OCTOBER 20, 1883.

ORIGINAL LECTURES.

GENERAL INTRODUCTORY LECTURE

Delivered at the Opening of the One-Hundred-and-Eighteenth Course of Lectures in the Medical Department of the University of Pennsylvania, October 1, 1883,

BY ALFRED STILLÉ, M.D., LL.D.,

Professor of Theory and Practice of Medicine.

GENTLEMEN,—The motto on the seal of the University—" *Literæ sine moribus vana*"—was no doubt intended to teach that learning is vain without morality; but the word *mores* really means manners, and the phrase signifies that one's manner of thinking and of acting towards other men not only stamps the moral character of the man, but also gives to his literary and scientific attainments their just value.

The word "*mores*," then, in our motto embraces the whole of a man's life, his manners, as well as his morals, and, above all, it sets up as the standard of conduct that which has been established by custom,—for such is the meaning of *mores* in the singular number. In the history of the world custom has the force of law. Many things that are immoral in one country or at one period are held to be moral and even praiseworthy at another epoch or by a different nation. A long-established custom may generally be regarded as having a real ground for its existence, and ought not to be laid aside without an equally substantial reason.

These thoughts have been suggested by published statements that certain medical colleges proposed to dispense with introductory lectures. Pardon me if I say that they struck me very much as a resolution would for gentlemen to dispense with the customary salutations which, in one form or another, are common to barbarous and civilized nations, and whose omission is everywhere regarded as insulting.

In every European country the annual opening of the medical schools is and has been from their very foundation celebrated as a festival, and a formal discourse is pronounced by a member of the Faculty upon some topic more or less directly related to medicine. A century and a half ago, themes such as these were chosen for the

introductory lecture of the School of Paris: "The Search after Truth in Medicine;" "The Obligations of a Christian Physician to Religion and his Country;" "The Maintenance of Harmony between Physicians and Surgeons."* To this day there is not a medical school in Europe where the same ceremonious inauguration of the year's duties is not observed in a similar manner. The University of Pennsylvania inherited it from the schools of Leyden and Edinburgh, and has transmitted it to the younger generation of medical colleges in this country. Formerly each professor delivered a lecture introductory to his own course, and the whole of the first week of the term was consumed by these lectures alone. More than twenty years ago the present plan of giving a single and general introductory lecture was adopted, and under it, as the representative of the Medical Faculty, I formally introduce you and my colleagues to one another, and hope that an acquaintance so cordially begun may ripen into a friendship that shall never die. Persons so introduced, even for business purposes, if they are well-bred, or even if they understand anything of human nature, will abstain from plunging at once into the special matters that concern them: they will spend a little time in trying to learn something of each other's disposition, motives, and objects, by conversation upon general subjects. I therefore follow the precedent set by many generations of professors, and ask your attention to certain topics which are more or less related to medicine, and about which you will, perhaps, not be displeased to hear an expression of opinion. It has been said that introductory addresses are not always to edification; that the speaker is under bonds to magnify his colleagues and the institution he represents. I shall not so far overstep the bounds of modesty. The Medical Department of the University needs no blare of trumpets to celebrate the yearly opening of its doors. But the occasion is one when it may be profitable to consider some of the claims of medicine to our reverence and duty, or rather to the duty of active service because of the reverence which is her due.

Devotion to medicine may be exhibited by fostering whatever tends to perfect a

* Corlieu, *L'ancienne Faculté de Médecine*, p. 131.

knowledge of it, or, in other words, by promoting the most perfect methods of education and practice. The education itself cannot be secured by the wisdom of its plan alone, nor merely by wise enactments of either state or college. Like everything else that has its roots in nature, the development of knowledge needs time for growth, as well as a proper soil and the fostering influences of sunshine and rain. It is well to remember that the bulky and succulent animals whose flesh now enables man to endure the severest toil were once small in size, and of tough fibre; that the swift, docile, and intelligent horse of Arabia or England is a very different creature from the coarse and wild animal from which it is derived; that the grains upon which mankind depend for daily bread were little more, originally, than weeds; that the fruits most renowned for size, aroma, and flavor were once insignificant, and crude, and harsh; that all the glories of modern horticulture have been developed by the patient art of man out of plants as simple and vulgar as the weeds that skirt a country road or thrive in the forest solitudes. And, more than this, we should remember that that still finer product, the flower of intellect, can only be developed by the most intelligent application of means that have been tested by the experience of ages. There is neither a royal road nor a popular by-path to knowledge. Knowledge is the food of the mind, and it must be subjected to processes like those by which material food nourishes the body. All material growth is the outcome of food digested and assimilated; and as strength is a result of growth, so wisdom is to be gained only by appropriating the lessons of nature and the experience of mankind, making them verily bone of our bone and flesh of our flesh by feeding the mind with the products of infinite wisdom and human intelligence, until we grow into the most perfect type of humanity and likeness to the Divine.

Physical differs from intellectual development in that it is limited by physical laws; but no limit has been discovered to the expansive powers of the mind. Yet high as its attainments have been, and higher far as they may be hereafter, there is but one way of securing them, and that is by gradual progress; literally step by step, and with constant watchfulness that each

step shall be a real advance upon ground so solid that it may be safely used to advance towards that ideal state in which every man can secure the knowledge required by his chosen career.

On something like this ideal plan the education of Europe has long since been framed, not, as here, by the chance association of well-intentioned individuals, but as one of the proper functions of the government; and hence in its most cultivated nations professional studies cannot be taken up at will by the ignorant and untrained. On the contrary, the youth almost from his cradle undergoes a systematic and progressive training in school, gymnasium, and university, and acquires, little by little, that discipline of his faculties, and that aptitude for gaining knowledge, which render his higher professional studies natural, easy, and profitable. Towards such a consummation as this the best systems of instruction in this country are tending, training the mind and the character for the various paths of usefulness, honor, and profit in life. We are gradually getting rid of the barbarous notion that each man is as fit as his neighbor for whatever vocation he may choose, and as gradually becoming convinced that for each professional career no amount of preparation can be too great, and that the only training which really insures legitimate success is one that begins in childhood and is steadily pursued and expanded over a constantly widening field until it reaches the level of professional education. It is perhaps true that no such systematic education can yet be generally exacted, but it is doubtless equally true that there is a large class, which is rapidly growing larger, of persons who, for themselves and their children, are determined that the means of acquiring the most perfect education shall not hereafter be lacking, and that, let others do as they will, let others sneer as they may at science, scholarship, and discipline, as for themselves they will serve no other cause than that of acquiring and imparting the knowledge on whose possession the rank of our country in the civilized world depends.

It may be difficult not to complain of the slow development of medical education in this country, but we should not be impatient, nor, least of all, discouraged. We should not forget that in every onward movement of civilization time is an es-

sential element. It is easy, on a superficial view of our medical history, to blame the apathy of the profession, but, on a deeper investigation, it is quite as easy to discern the causes of our slow progress, and the tardy and imperfect results of the well-meant and zealous efforts that have been made to improve our methods of professional instruction. Not now for the first time does the question of a higher medical education occupy the attention of American physicians. It is not by the movement in advance of Harvard or of our own University that the new departure began; it was not with the establishment, in 1847, of the American Medical Association for the sole purpose of promoting this object, that the agitation commenced. Long before that period the prophets made the land resound with lamentations over the ignorance of physicians, and held up side by side the short and meagre curriculum of our education and the prolonged and elaborate instruction of European physicians. Here and there among us were men who hung their heads and blushed for shame, and here and there some spurred forward to do battle for the truth, but, too often finding that their weapons fell upon stolid mountains of ignorance or on the stony walls of prejudice, they retreated discomfited and discouraged. The fulness of time had not yet come, nor has it come even now. The day is breaking, but noon is still far off. A century, almost, has passed, and we are yet only struggling into the light. We take pride in the unexampled growth of our country in population, wealth, and industry, in the mechanical arts, and in whatever ministers to the physical well-being of the nation, but whoever looks critically at our condition must admit that a corresponding progress has not been made in moral and mental culture. In the natural order of human progress the material must be developed before the intellectual, but the more closely we consider the history and actual state of the question the plainer does it become that our material prosperity has advanced in a disproportionately rapid manner, that whatever is supposed to lead to wealth is fostered by legislation, and that whatever has only intellectual claims is very apt to be ignored, if not contemptuously treated, by our legislators.

The ancient examples of the first colonists of Massachusetts and Virginia are apparently unheeded. It seems to be for-

gotten that these two colonies, the one among the smallest, the other one of the largest, took the lead in all the affairs of the nation by sheer force of superior cultivation, and that to this day one of those States holds a similar pre-eminence and owes it to the same cause. These and similar examples seem to be overlooked by, or are unknown to, those whom we elect to make our laws, and our legislatures spend their time in regulating trade, and manufactures, and agriculture, and other material interests, when they are not engaged in wrangling over the plunder of the public purse. The things that make a nation really great, the laws that compel as well as encourage the people to understand that life has higher aims than riches, better rewards than silver and gold, are either neglected or are enacted and administered without intelligence. Above all, and worse than all, the examples I have drawn from colonial times are unheeded, even if they are thought of, which they probably are not. Our ancestors, paraphrasing the ancient fable, concluded that although the several members are necessary to make up the whole body, and no one of them can continue to exist without the others, nevertheless the brain is king over all. And hence, while they provided for instructing all children in the rudiments of knowledge, they took care that those who were destined to a professional or scholarly or scientific career should have access to the best instruction that the time and the country afforded. These principles, be it observed, and these provisions were those of our English ancestry, of monarchists and not republicans, and, in the case of Virginia, of aristocrats and not democrats. Perhaps for that very reason when the colonies were fused into a nation it came to pass that whatever interest was displayed in legislating for education generally exhausted itself in trying to improve the primary and secondary schools, while higher knowledge and professional education were left to struggle for existence as best they could. Even worse than that: broods of colleges pullulated all over the country, many of which were not even respectable grammar-schools, and medical colleges were established in villages whose very atmosphere was fatal to science, and with professors whose ambition, however great, was not sufficient to excuse their ignorance, and who, never having had any

trained clinical education themselves, may perhaps be pardoned for believing that physicians can be made of young men who have never studied disease at the bedside under trained instructors. While the very fountain of supply of the medical profession was thus yearly becoming more impure, and graduates were multiplying who instinctively defended their own ignorance and the system that produced it, the better-instructed physicians of the country never ceased to protest against this evil and to propound measures for its cure. It was not clearly seen that to impose a more thorough system of education on nine-tenths of the medical schools was like bidding the cripple to "arise, take up his bed, and walk." How could they be expected to have the faith that works miracles? They, too, had regard for the "loaves and fishes," and so they have, for the most part, continued to crawl in the old and beaten path, and let who would outstrip them. Unfortunately, they not only use the path, but they cumber and obstruct it; they lie, as it were, across it, and hinder the advance of others who are more vigorous in action and of larger views than themselves. In plain terms, these obstructive schools, whether in villages or in populous cities, seduce to themselves young men who would otherwise have sought their education in colleges of a higher grade, and thus by one and the same act hinder the good work of their rivals and retard the professional advancement of the young men whom they graduate. It is probably safe to predict that so long as free trade in medical education is unchecked the most meritorious colleges will fail to attract to themselves the greater number of students, and the hope of educational progress, which has aroused the enthusiasm of not a few in each generation that has passed, will still remain an unfilled dream.

Is there no hope, then, except in the colleges that prefer character to emolument, and who have taken upon themselves the dangerous duty of leading the forlorn hope in its attack upon the strongholds of ignorance and selfishness? Is there no prospect, under our political system, of there being a restoration of those methods which were never before separated until they were torn asunder violently in our own age and country? Have knowledge and culture any essential antagonism

to freedom and political equality? Is there any necessary incompatibility between being at the same time a gentleman and a good citizen, a scholar and an honest man? Are we so far below the standard of the ancient republics that, unlike them, we can afford to despise knowledge and to foster ignorance?

To these and similar questions no one, I presume, will venture to give an answer that implies a confession of national or professional decline; and yet no one, I imagine, will be so bold as to assert that during this century and more of our national independence we have as a profession kept pace with the professional advancement in other countries, or even with the progress of those who cultivate other branches of natural science in our own country. Compared with American naturalists and scientists generally, the American physician does not shine. The written medical publications of the country, as a whole, and with some brilliant exceptions, are remarkable for superficiality, inexactness, partiality of survey, lack of largeness and firmness of grasp; and these defects are painfully conspicuous in our periodical literature. True, very true, several cities could be mentioned where the narrower provincial traits have become partially effaced; but it is because in them many of the leading medical men have served a second apprenticeship in foreign schools, and therefore shine by contrast with the background they illuminate. After all, it happens that the sonorous resolutions passed by our local, State, and National medical associations, the addresses of teachers, the essays in journals, and even the general *consensus* of the cultivated medical men in the profession, have not produced, except at two or three points, any material enlargement of the sphere of education. It would seem as if there was something both rationally and morally wrong in our judgment, when we see systems that have been wellnigh laughed out of existence on the other side of the ocean accepted and widely propagated here, and coquetted with by some of the most conspicuous members of the profession. Even worse than this, the pillars of professional dignity have been shaken, the bonds of professional morality have been loosened, and an effort made to abrogate the ethical law which has heretofore governed the profession, or to

substitute for it another expressly contrived to pander to acts that have hitherto been held as criminal. Our unlimited freedom has tended to loosen the bonds of professional brotherhood: once being assured that every man may become a law unto himself, professional disintegration will be hurried forward with the rapidity of geometrical progression. In a word, it has become only too plain that life without a head, however compatible it may be with zoophytic existence, is not so for the higher organizations to which our profession belongs. It is immortal, and can only "by annihilation die;" but whether its life shall be vigorous, productive, beneficent, and honorable, or feeble, barren, hurtful, and degraded, the events perhaps of this very generation may determine. I have no pretension to reconcile the incompatibilities of the subject and bring the politics of the day into harmony with the serious interests of science. A more monstrous conjunction would be difficult to conceive. Nevertheless, it seems to me that possibly by creating, first a thoroughly-educated medical profession, and then a delegated representative body from within it whose enactments should have the force of law, a legal tribunal might be established in each State, an *imperium in imperio*, which should have the absolute control of all things medical within the commonwealth. Is this a practicable plan, or is it only a chimera,—a nightmare engendered by the impossibility of digesting the manifold crudities of the existing state of affairs?

It must not be supposed, however, that any method of improvement, however wise in itself or well considered, can at once be made acceptable to those for whose benefit it was designed.

It is related of an eminent statesman that at the very entrance of his official career he was confronted by the stubbornness of the routinists and by the amazement of the ignorant. They were equally persuaded that nothing was possible beyond what their own narrow field of vision had made familiar to them, and he wasted his strength upon these obstacles as waves dash in vain against the cliffs. Just such a fate is too often reserved for men and for institutions who are better informed than their rivals, and who, animated by a nobler spirit of progress, are ambitious of having their work more perfect than they received

it; who endeavor to substitute fresher materials and more productive measures for those which have become effete or obsolete, and to breathe into a torpid body the vigor and animation of renewed youth. In literature, and even in science and art, the greater number are persuaded that their own particular coterie or school, the attainments of their own generation, the methods pursued in their native town or country, represent the *ne plus ultra* of advancement, and they are apt to resent as a personal affront every attempt to improve them. They too often forget that they stand upon a higher plane than their predecessors, and that the next generation will stand upon a superior level as certainly as that the sun at noon is higher above the horizon than at the dawn of day. Few things are recognized by men with more reluctance and difficulty than that they are not the centre of the universe; that in fact they are seldom anything at all unless they transmit to those who come after them the light they have received from their predecessors. It is not the physical characteristics, nor the moral qualities, nor the material wealth, alone, of one generation that descends by inheritance; quite as certainly the genius, the skill, the harvest of knowledge of successive generations and of individuals, are so transmitted. Well, then, may we cry shame upon those who stint posterity of its rights by a negligent or even by an unintelligent culture of their field of labor, or, worst of all, who dwarf the mental growth of those they educate by repressing criticism, by discouraging inquiry, and by the administration of that potent carminative, flattery, soothing even the restless minds of the young into a sweet contentment with ignorance and stagnation.

For more than half a century, as I have already said, there have never been wanting some who rebelled against the tyranny of educational routine, and who labored, for the most part in vain, to have their views accepted. How strange it seems that a country which prides itself upon its progressiveness, and justly so in material things, should be so far behind others in the highest departments of general and professional education,—a country, too, whose people, by the intermarriage of races, by political and social liberty, by abundance of food, by varied indus-

tries, and by experience of the vicissitudes of life, are the most actively intelligent of all the nations of the world,—how strange, I say, it is that they should still lag behind in the nobler fields of knowledge, and that those who have gathered the fullest harvests therein should find so few to understand or value them! Nevertheless, it cannot be doubted that this small number is increasing every year; that the voice which so long has been crying in the wilderness is at last echoed here and there by kindred spirits; that the long-buried seed is springing up to gladden the barren places of ignorance; and that the intellectual development of the nation will in the near future rival its material prosperity. While we are diligent in promoting whatever may quicken the advancement of medicine in its teaching, its science, and its practice, let us not be impatient. Let us remember the sublime image of the prophet that the Almighty was not in the whirlwind, but in the “still, small voice.” All beneficent advancement in the social, moral, intellectual, or political condition of mankind has been the outcome of slow and gradual changes which were often hardly perceptible, or at least did not attract general attention. The infant of one period becomes the adult of another by such silent development that the successive changes can only be measured by a comparison of widely-separated epochs.

What has been said of professional and national development is no less true of every individual's education for active life. The knowledge implanted during the long seed-time of childhood and youth, and even in the maturer period of early manhood, is slow in bringing forth its fruit; nor is it all grain fit to furnish the bread of intellectual and moral life. It obeys the law of universal nature that all fruit shall be small in comparison with the plant that produces it; the law that encloses the life of the great oak in the tiny acorn. Look at the sheaf of wheat before and after it has been threshed, and observe how little it has lost of its bulk; yet all that was valuable in it has been removed, and what remains is fit only to be trodden under foot of cattle. It is no less true of knowledge that its seeds germinate in darkness and often in unclean soils; that although it waxes larger and stronger, it may for a time give no promise of fruit; that even when its fruit is

matured it must still be winnowed from the tares of error; and that the residue of all this waiting and watching and culture is a very small bulk indeed compared with all that must be thrown away as valueless. But then this residue is the quintessence of knowledge, and contains within itself the vital principle out of which spring new truths to cover the fields of science with harvests to the very end of time. Let us not then expect or attempt to contravene the laws of nature, nor suppose that a harvest can follow immediately upon the seed-time of learning, whether it be of individuals or of institutions. The qualities of the young are adapted to them,—their faith, hope, enthusiasm, energy, and diligence; but they may lead to no immediate result. They are fair blossoms, but the fruit is in the future. Not that it will reach maturity as a matter of course; not without protection from frosts that kill and droughts that wither, and, above all, not without that innate vitality which all through the period of development gives the surest indication of the ultimate perfection of the fruit.

Moreover, the attainment of success is seldom like the growth of grain in well-tilled fields, where everything is propitious to its perfect development. It involves a perpetual conflict with antagonists and surmounting of obstacles. A traveller has told us of a mountain-side sprinkled with blocks of granite, so that most of the trees are obliged to twine their roots over the rocks or split them asunder in order to reach a little earth to nourish them, and yet they force their way upwards to a surprising height, and seem to grow into one with the rocks, so that they stand more securely than their easy-going comrades who are rooted in the tame forest-soil of the level country. So it is in life with men who have become great because they have strengthened and established themselves by subduing the obstacles that oppressed their growth.*

In this conflict the direction of the result is determined by the accidental relation between the active and passive forces engaged. But in every man there is a power to rough-hew the end, although the Divinity may give it its final shape. The forces that determine a man's career may be likened to those which propel and guide

* Heine, Pictures of Travel.

a steamer. The engine turns the wheels constantly in the same manner, moving the vessel onward, from whatever quarter the wind may blow or however the current may run. It is the pilot at the wheel that shapes its course in this or that direction, towards this or that haven. So the impulsion of genius must be directed by the guiding power of reason and judgment. The impulse may become dangerous without the controlling quality, and the judgment that directs would be in vain without the impelling force. All the great masters of knowledge of mankind have recognized this double influence that determines our career in life, our own will and the power of circumstances, and have shown how far it is possible apparently to bend events to favor us. I have already alluded to one expression of it. Here is another:

"Men at some time are masters of their fates:
The fault, dear Brutus, is not in our stars,
But in ourselves, that we are underlings."
Julius Caesar, Act 1, Scene 2.

But I cannot pause to develop these ideas belonging to a subject which concerns us very deeply, because it relates to our conduct and success in professional life. Out of the many others that present themselves is one that by long habit, if not by natural instinct, attracts me more than others, for it seems to me that upon a right judgment in relation to it depend a physician's genuine success and reputation. I say *physician*, and not medical scientist: the man whose business in life is to cure diseases, and not the one who occupies himself with speculations or experiments regarding their nature or the physiological action of medicines. What Emerson* said of art in general is quite as applicable to the art of medicine. "Man is but 'naturæ minister et interpres.' As long as he watches for the signs she holds out for his guidance, his road will assuredly lead him towards the truth; but as often as he busies himself in finding out inventions which are evolved from his own consciousness, he wanders from the straight path and will inevitably be lost in the desert of doubt or in the quagmires of error." This is the philosophy of Bacon, by which all modern science is justified. On the other hand, may be found in a leading medical journal of Europe the following: "A medicine or a therapeutical method should not be em-

ployed merely because its successful applications are numerous enough to inspire confidence in its power. What is necessary above everything else is that the physician should *understand the precise nature* of the treatment he employs, the precise line of conduct he should pursue for each disease; not the more or less complete statistics of empirical results, but a clear and distinct explanation of the therapeutical effects, based on experimental physiology and clinical observation."† Blind leaders of the blind are such teachers as this one, who, seeing but half the truth, and that a subordinate and non-essential part, exalt it into the supreme, if not exclusive, power. As teachers, they train up pupils who, unless they resolutely tear away the errors that blindfold them, will find themselves discredited by the wisest men of their own generation, and out of harmony with the empirical art which has survived and governed from Hippocrates until now. During all these ages, the medical hypotheses and systems that have flashed a momentary glare upon the world have, like the utterly useless fireworks they resembled, gone out in stench and darkness. If there is one idea more absurd than another in regard to practical medicine, it is that the efficiency of treatment depends upon its being intelligible, or, conversely, that the physiological action of a drug bears any uniform relation to its therapeutical action. Are we so blind as not to see, so dull as not to apprehend, or so wrong-headed as not to acknowledge that in the list of medicines that has lengthened out from the beginning until now, and will hereafter stretch to the very crack of doom, there is not one, no, not a single one, whose virtues were discovered by science and not by empirical observation? Philosophers no more discovered medicines than they invented food. The instinct that taught man to eat also taught him to seek in the natural objects around him, and in the fruits of his own invention, the means of relieving pain and curing disease. As an art, medicine is next in antiquity to that by which men learned to distinguish wholesome from noxious food, to produce fire, to find shelter from the destroying elements, and defence against wild beasts and hostile men. When man began to suffer from wounds and bruises, the same

† Lambert, Bull. de Thérapeutique, lxxix. 5.

instinct impelled him to seek and led him to find remedies for them, and to hand down his knowledge to his children and his children's children. As the river that bears great fleets upon its bosom may be traced through many a winding with constantly narrowing stream until its source is discovered in some tiny rill far away in the recesses of the mountains, so all human knowledge, so, above all others, medicine and its twin-sister religion, had their birth in that remote and mysterious primeval region which the faith of all nations has pronounced divine. Who taught man medicine? Who taught man worship? To these questions only one answer can possibly be given,—the power that created him and that made him what he is. And let it not be forgotten that he shares the medical instinct with the brutes, and that even they have always been his guides, and were perhaps his first teachers. If any one finds in this an ignoble origin of the art of medicine, let him consider whether religion is degraded by springing from the terrors of nature on the one hand and her beauty and goodness on the other. Let him also ask himself whether the grandeur of the oak or the charm of the rose is lessened because its roots are embedded in dirt and decay. It is the shame of the arts and sciences, as it is of many men, that they try to ignore or to conceal their humble origin, although nothing but imbecility should prevent their remembering that a few generations ago, more or less, they too were sons of the soil.

Yes, there are some who seem to believe that medicine sprang full-grown from the brain of Minerva, as the goddess herself was fabled to have sprung from the brain of Jupiter. They ignore everything before Galen or Hippocrates, when they ought to know that even the greater of these, the father of medicine himself, invented far less than he compiled, and that his works, as they have come down to us, represent not so much his own genius as the growth reached by medical knowledge in his day. The scientific physicians of the present generation too often remind one of the iconoclasts of the English commonwealth and the atheists of France. They found it easy to destroy, but to supply the place of what they destroyed was beyond their skill. By infusing into the popular mind a portion of their own self-sufficiency they have helped on the baleful work of the Nihilists,

whose creed is a negation and whose aim is destruction, so that now on whichever side we look are heard only the scoffs of these self-enlightened people at everything on which the soul's faith and the understanding have securely rested from the beginning. They sneer at virtue as a mere matter of temperament, a constitutional state that has no more to do with conscience or responsibility than one's sex or the color of the skin. They would dethrone the Lord of heaven and earth; but while they laugh at religious faith they worship the little idol they have evolved out of their own consciousness, and whose proper name is vanity. They deride the wisdom of ages, and would create anew the science and art of medicine, not considering that there must come after them a generation that will treat their doctrines with the contempt that they themselves pour upon those of their predecessors; not even conscious that all their lives they have been sapping the faith of the people in that which, next to religion, they have always venerated, and rendering physicians themselves sceptics, if not scorners of the art by which they live.

Yes, for this and for much more evil are the overweening pretensions of misplaced medical science answerable. They are responsible in a great measure, also, for the wave of quackery under which the medical profession is in danger of being submerged. For the people instinctively argue, "If physicians no longer have faith in medicine, why should we have faith in them?" and therefore they wander off into the abominations of quackery, be it gross and vulgar or take the shape of ethereal quintessences, simply because the prophets of these false systems are wiser in their day than the children of light, and "wear the livery of heaven to serve the devil in," and are, above all things, self-confident and incapable of shame. The so-called intellectual regions of our country are precisely those in which these miserable frauds prevail and thrive most vigorously, where physicians are most prone to proclaim the nonentity of their art, where human rights are held to be superior to human duties, where the brain, the intelligence, is so strained by education and by the habits of life that it oftener than elsewhere is shattered or withered, while the heart, the moral nature, becomes chilled, and dwarfed, and shrunk, and the moral aspects of life,

the sentiments of reverence, of gratitude, of pity, sympathy, and love, are felt to be encumbrances in the struggle for wealth and distinction, and are not allowed either to sanctify research or to consecrate its fruits. No, gentlemen, no! "What God has joined together let no man put asunder." Science and art are portions of one complete whole. But while natural science cannot exist without art, not only can art exist without science, but it always did exist before science was dreamed of. Medical art changes but little, except as a tree is changed in growing, but medical science is a creation; the science of to-day is very different from that of yesterday, and we may be very sure will be found quite unlike the science of to-morrow. The history of medicine may be pictured as two streams whose general direction is parallel, and whose waters, if for a time they mingle, on the whole pursue an independent course. Theory is sometimes a stream rushing over a stony bed between rocky and treeless shores, tumultuous, winding, shallow; sometimes like one of those rivers of our West, issuing in great volume from the mountains, but dwindling as it goes, until it disappears in the barren desert. But art, be it medical or any other art, is a broad and, it may be, almost a sluggish stream that creeps or sweeps onward between banks that widen as it goes, fertilizing them in every portion of its course, filling granaries with corn and storehouses with wine and oil, and planting marts of civilization on its shores. Art it is that has given us all the resources of medicine, which, if we use them aright, will bring honor to it and profit as well as honor to ourselves; but if we slight it, if we deride it, if we proclaim our disbelief in it even while teaching or practising it, we bring discredit upon what it is our misfortune not to have comprehended, and set an example of faithlessness which we may be sure that the unlearned in medicine will use to justify their own apostasy.

At the risk of exhausting your patience, I venture upon one more reflection suggested by the previous remarks. I wish to remind you that medicine, although it has existed from at least the time of Hippocrates, twenty-three centuries ago, had not, and could not have, during more than two thousand years of that period, any foundation such as we now call scientific, for until about two hundred and

fifty years ago the circulation of the blood was unknown. Later still came the discoveries that, along with the circulation, constitute the basis of modern medical science. Then, and only then, for the first time was it learned that the animal organism is developed and sustained by the conversion of food into flesh and blood on the one hand, and the supply of air on the other hand; still later than this it became known how all the vital movements of the organism as a whole, and all the mutual relations of the different organs, are maintained by the mysterious power of the nervous system; and finally it was learned how the body is doomed to death by the inevitable decay of the mechanism upon which the maintenance of life depends.

I say that all this science of medicine, and infinitely more connected with it, is a creation of but yesterday compared with the venerable antiquity of medicine as an art. It is evidently, therefore, independent of the art, as the art is independent of the science; and whether the science be true or false, and in whatever degree true or false, it has no more essential connection with the art of healing than the theory of the tides has to do with the actual flux and reflux of the ocean that surrounds the earth. It is of importance to us all, and at every stage of our medical career, but of the utmost importance to those who are just entering upon the study of medicine, to keep clearly before them that medicine has two sides as distinct from each other as all facts are distinct from the explanation of those facts; that while the one is essential, and if true is everlastingly true, the other is but of yesterday, is always vacillating, and can never be absolute, and that however much it may assist the mind to group together medical facts and refer them to general laws, it can never be more than a provisional formula. In the sphere of actual practice all hypotheses, theories, principles, must be subordinated to empirical rules, for they are founded upon the observation of disease and not upon the conclusions of scientific theories, and are as true in this nineteenth century as they were two thousand years ago, before the circulation of the blood was dreamed of, or a single organ of the body was accurately known in its structure or its function. The aim of science is to explain what art discovers; but the discovery

remains, whether the explanation be true or false. By all means let us use the principles of science in studying disease and its treatment, but use them as threads to guide us in the labyrinth of research, as scaffolding to aid us in building the solid walls of concrete facts, so that when we have reached our goal we may cast away the thread; when we have raised the temple we may throw down the scaffolding that is no longer useful.*

* The remarks in the text are in harmony with what appears to me to be the true and legitimate spirit of medicine as it is displayed in the writings of all ancient and modern physicians who have really enabled us to improve the cure of diseases. They represent the spirit of the English and French schools of medicine as opposed to the German and Italian schools, the clinical as contrasted with the speculative methods of studying and treating diseases. In each of these national schools there are exceptions to the rule which governs them; but as a whole the former are practical, the latter are theoretical. In the United States, where a large proportion of the best teachers have been trained in European schools, and especially in those of Germany, and where many of the leading physicians are born and educated Germans, it is not to be wondered that the peculiar medical doctrines and methods of that country should have been imported here and engrafted on our medical body. That these doctrines and methods are discordant with the essentially practical genius of Americans, and must sooner or later lose their influence, appears to me certain. But, in the mean time, it behooves all who have an opportunity of addressing medical students to warn them against the barren and injurious methods of thinking and practising which are tending to destroy our faith in medical art, and which have already carried tens of thousands of patients away from true medicine into the absurdest and most mischievous systems of quackery.

The absurdity and danger of "scientific" medicine in practice have been a thousand times exposed in ancient and modern times, but I venture to place on record here one or two utterances respecting it which most accurately express my own convictions. Some fourteen years ago, Dr. Elam, in London, wrote as follows:

"Medicine should be, before all things, the *art of healing*. Our first and fundamental error in theory has been the overlooking of this definition, and viewing medicine as a science. Now, in any proper acceptance of words, medicine is not, and can never be, a science; it is an art *sui generis*,—fed, fortified, and enlightened by science,—but in no wise a science in itself. This is not a mere speculative matter,—an affair of terminology. So long as we view medicine as a science, so long shall we be disappointed in our progress and our results. Science is steady, certain, and progressive; art is vacillating, doubtful, and limited. If we expect exactitude and certainty in medicine because we rank it as a science, we shall be ever failing, ever doubting, and losing our faith, and, as a necessary consequence, our zeal. We can never hope to reduce medicine to mathematical formulas in which disease and remedy will represent one side of the equation, and health the other. We deal with such an infinite variety of unknown quantities and indefinite variables that we can never hope to reduce them to any fixed expression that can have a practical value. Besides disease, we have to deal in each case with age, sex, temperament, and previous history,—elements which can to some extent be allowed for; we have also to deal with idiosyncrasy, with heritage, and with the thousand social surroundings which will always baffle our calculations and stultify our foregone conclusions. . . .

"Science is knowledge, but such knowledge is not power in any practical sense. . . . By science we know disease; science is diagnostic. It is by art that we treat it; art is therapeutic. All our art is derived from experience. . . . Science knows, and is precise and positive, art is variable and selects. Science submits to no ignorance, but art is ignorant of much. Science is essentially contemplative, art is active. . . . 'Science puffeth up, art buildeth up.' . . . Pure science has, in general, done but little for art, while art has constantly and largely been contributing to the progress of science. . . . Medicine has the same relation to science that poetry or painting has; and inasmuch as the most complete knowledge of the laws of perspective and the theory of light and colors would fail to make a painter, or the most intimate acquaintance with the rules of versification would

But I must hasten to conclude this address, made fragmentary by the very pressure of the topics that clamored for a hearing, and in doing so beg you to look beyond your present studies and keep your eyes fixed upon some elevated goal that you intend to reach. We are often bidden to take short views of life, to take no care for the morrow, to bide our time, and the like, precepts that may have their application, but it is not for you. On the contrary, what your studies are, and the spirit in which they are pursued, such in all probability will be your future attainments and prosperity. It is only the weak and narrow-minded man who bounds his horizon by his daily work. The strong man is the hopeful man who fulfils his own hopes. He is like the navigator who steers by his compass and the celestial bodies, and spreads his sails to catch every favoring breeze, knowing that beyond the visible horizon lies the haven towards which his hopes of fortune impel him, and that if he guides his bark aright success will sooner or later crown his voyage. The wise man has warned us not "to make haste to be rich," and the warning is no less worthy to be had in reverence by those who seek the riches of wisdom and knowledge and skill and power than by those who covet riches that are of the earth, earthy. No more than Rome was any man's fame ever built in a day. It is the result of patient labor, of sagacious foresight, of daily additions to knowledge, of incessant training of the faculties, while

fail to make a poet, so the profoundest knowledge of physiology and of all the sciences tributary to medicine would entirely fail to make a competent physician. *Medicine is a faculty to be acquired, not a lesson to be learned; . . . not to be reduced to the hard and inelastic formulæ of science. In itself, I reverence science; but, in the interests of true progress and of humanity, I trust we shall, for the future, hear more of the art of healing and less of the science of medicine.*"—*London Lancet*, June, 1869, p. 775.

Nearly ten years after the utterance of these admirable truths they were echoed in the Hunterian oration of Dr. Moxon: "The biologist and the physician," he says, "work in opposite directions, if upon the same lines. The biologist, if he shows any aim at all, stretches himself out to learn the first beginnings of life and its smallest minutiae. The task of the physician is in quite a different direction. . . . The physiologist considers the origin of the spirit of life, while we have to consider the very different question of how the living thing beats itself to pieces. . . . Our modern tendency is to spend the larger part of a man's time in teaching him professional biology; and there is growing up a generation of physicians, through the long prevalence of that system, who are so imbued with the scientific spirit as absolutely to forget, in the highest issues, that their profession has any practical aim."—*Medical Times and Gazette*, March, 1877, p. 228.

To the acceptance of these doctrines the medical profession must sooner or later return, as it always has done after a season spent in "whoring after false gods." The theories that have from time to time enslaved it are, after all, but superficial influences, while all the while the great body of medical art founded upon clinical experience has remained as undisturbed, during the lapse of ages, as the depths of the ocean are by the storms that vex its surface.

the mind is steadily fixed on the proposed end, and every power is strengthened by the effort to attain it. Weak men live from hand to mouth, from day to day; they are literally day-laborers, and their rewards are, in like manner, transient. They lay up no capital for future use. They are like architects who construct many foundations, but build nothing upon them, and, in the end, leave behind them only the ruins of what should have grown into palaces and monuments. Strong men, wise men, are not solicitous about the judgment of the world on their unfinished plans: they do not waste their time and strength in courting the applause of the transient present. They let their work speak for itself. If it is approved by those who are fitted to judge, so much the better; but if it is not, none the less do they persevere in their determined plan, assured that, if they have judged rightly in the beginning, they will in the end reap the reward that never fails to crown sooner or later all that is substantially excellent. It is sad to see how much wasted power, how much misdirected zeal, how much untimely withering of fruit, there is in the world; how much labor is unrequited because it had no fixed purpose to attain; how many a goodly harvest is lost because it was put to the sickle before it was ripe. "Bide your time," my young friends, but abide not in idleness or sport, but in diligence, in steadiness, in perseverance, and, above all, in that faith which overcomes,—faith in yourselves and in the end on which you have fixed the eye of your ambition.

"Build, that the walls to coming generations
Your skill, your strength, your faithfulness, shall tell;
That all may say, as storms and centuries test them,
The men of old built well."*

THE GENIUS OF MEDICINE.

*An Inaugural Address delivered at the Opening of the
Fifty-Ninth Annual Course of Lectures at the Jefferson
Medical College, Philadelphia, October 1, 1883,*

BY THEOPHILUS PARVIN, M.D., LL.D.,

Professor of Obstetrics and Diseases of Women.

GENTLEMEN,—A just conception of medicine is essential to the best medical study and to the most successful medical life. He who would be a physician, indeed, must know the true character of medicine, its spirit, its genius. As thy

faith is, so shall it be unto thee, has a far wider meaning than that which belongs to a single event of life. Thy faith? Thy conception, thy belief, thy ideal, thy fixed conviction, a power permeating the soul, *informing* desire and thought, pervading words and deeds, and living in thy life.

It is, therefore, believed that the Genius of Medicine is an appropriate theme for the occasion,—the beginning of the annual course of lectures in this honored institution.

But what is the Genius of Medicine? As the prism separates the solar beam into the many colors which, again combined, make pure light, so we may take the various characteristics of this genius, which, by their union, make its living power.

First, this genius, this spirit of medicine, is scientific. A witty Frenchman,† referring to the scientific claims of medicine, gives, as a positive proof that a science does not yet exist, the fact that such alleged science is held to be common property, adding, in illustration, "My porter does not hesitate to diagnose a disease, to point out its cause, to prescribe a remedy, and to predict the result. He thinks he has a right to do so, and it seems that he has, for one readily listens to him, and often follows his advice."

But tried by this test many an admitted science would lose its claim. Meteorology is a science, but are weather-prophecies confined to those who have studied it? There are many persons, both in country and in town, who have that

"Old experience which doth attain
To something of the prophetic strain,"

and who often foretell with great certainty the weather which the day or the morrow will bring forth; at least their prophecies are quite as frequently verified as the correct diagnosis and treatment of disease are made by the ignorant. Theology is a science, and yet a well-known lawyer, possibly more famous for his oratory than for his legal learning, does not hesitate to decide the gravest theological problems,—giving his solution from the platform with the greatest generosity to his suffering fellow-beings at fifty cents a head,—problems that have engaged the prolonged and profound study of great divines, such as Edwards, Stuart, Alexander, Hodge, Breckinridge, Thornwell. Law is a science, but

* S. H. Browne, Continent, October, 1882.

† Louis Peisse, La Médecine et les Médecins.

some man who never gave a thought to Blackstone or Coke, except possibly as suggestive of winter fuel, may offer to solve legal problems, and sometimes may predict the decision of a court, or the verdict of a jury, quite as correctly as even a Philadelphia lawyer.

But, passing from this negative criticism, Comte's definition of a science as that knowledge which enables us to foresee and foretell results, justifies giving this name to medicine. Let any case of common disease be examined by half a dozen educated physicians, and there would be in almost all instances entire agreement as to the nature of the malady, as to its course, and as to the means advisable to alleviate it or to shorten its duration. The natural history of diseases is so well known that the physician can in most cases foresee and foretell their course. "It is not essential to science that it be at any given time complete or free from error. It is called science in reference to the aims and methods of the intellectual process of which it is the result, not in reference to its own absolute correctness and completeness." What adventurous explorer in any part of the domain of physical science dare say he has seen the pillars of Hercules, that there is nothing more to learn, or nothing to unlearn?

The certainties in diagnosis and in prognosis given in recent years by the thermometer, the microscope, the ophthalmoscope, the laryngoscope, the spectroscope, and the sphygmograph, add to the just claim of medicine to be called science; and, finally, the electric light waits to reveal pathological changes in the living hitherto recognized only after death.

In the department of therapeutics very important advances have been made in recent years; indeed, the treatment of disease becomes every year more scientific, less empirical. In this treatment physicians generally prefer a few and simple rather than many and compound remedies, an Enfield rifle rather than a Gatling gun. But in this they imitate the great masters. Hippocrates used but few medicines. Sydenham half jestingly said that he could carry all the medicine he needed in the head of his cane; and Boerhaave, I believe, said that the enlightened physician could practise medicine with opium, cinchona, tartar emetic, wine, and water. If Hoffman were to return to this earth, he, while still

using his famous anodyne, would rejoice in the great advance made in therapeutics, and cheerfully recant the famous declaration of scepticism he made: *Fuge medicos et medicamenta, si vis esse salvus.*

While rejoicing in the important position which medicine holds to-day, the student must not forget that the foundations of our science were laid, and the form of the superstructure largely directed, by that noble Greek who must ever be among physicians as Alexander among warriors, Homer among poets, and Plato among philosophers,—the divine Hippocrates. It seems certain that neither the Jews nor the Egyptians made any important contribution to the beginning of scientific medicine, though recently it has been stated* that the physicians in the time of the Pharaohs recognized the heart as the centre of the circulatory system, and referred the beating of the pulse to its movements. Still other discoveries are attributed to the priestly physicians of the Nile.

Nevertheless the general rule is, as stated by Boyer, that in all peoples who have left durable traces in the arts and sciences, the arts have flourished first; the imagination awakens the other faculties, the poets open the scene, the philosophers and *savants* follow. But Egypt failed to take the first step. The Jews, indeed, had their poets, whose lips were touched with hallowed fire, and whose sublime utterances are for all the races and all the ages; but it must be remembered that this people had an admirable system of preventive medicine, and therefore but little necessity existed for the study of the cure of disease.

Darembert† has clearly shown that Greek medicine, the origin of the medicine of to-day, came neither from the temples, nor from the gymnasia, nor from the schools of philosophy, but from the laboratory of physicians. In Homer the medicine is quite human, and even on Olympus the physician of the gods used means familiar to the physicians of the Greek army. He further observes that theurgic medicine occasionally appears in the time intervening between Homer and Hippocrates, but true medicine still lived without eclipse, just as it lives to-day without eclipse by spirit-rapping, animal magnetism, or homœopathy. Æsculapius, who

* Dr. George Elbers, *Contemporary Review*, June, 1883.

† *Histoire des Sciences Médicales*. Paris, 1870.

was the chief medical officer of the Greek army, seems to have been brevetted for distinguished services: as he did not want an office, he was given divine honors. But, sad to say, getting his godship had a very bad effect upon his character; he became so extremely avaricious, he did worse than engage in the grave-robbing business, he went to breaking open the jail and letting prisoners out, provided they paid him well; in other words, he restored the dead to life. As this sort of work threatened to depopulate Hades, Pluto, who was engaged in the wholesale undertaking business, made appeal to Jupiter, who, very properly and promptly, with one of those many thunderbolts which he had at hand, knocked Æsculapius forever out of time. Since then doctors have let dead people stay dead, influenced to this conservative conduct quite as much by fear of the fate of Æsculapius as by the reason which Molière has put in the mouth of Sganarelle: "The best of this profession is, that there is the greatest honesty and discretion among the dead; for you never find them complain of the physician who has killed them."

But, leaving myths that came into the history of medicine after Homer sang the wrath of Achilles, let us see something of the work that Hippocrates did towards the establishment of scientific medicine. He emancipated medicine from superstition and charlatanry; he co-ordinated facts that had been collected, separated between the true and the false; he taught that pathology was a part of physiology; he urged the importance of careful clinical observation. Lord Bacon, whose great mind grasped so many subjects of human knowledge, irradiating all it touched, gives just honor and importance to medicine, but condemns "the discontinuance of the ancient and serious diligence of Hippocrates, which used to set down a narrative of the special cases of his patients, and how they were judged by recovery or death."

That the medical views of Hippocrates were eminently catholic is shown by the fact that many of the schools springing up after his day claimed his authority; but he belonged to none; he belonged to all, for he had uttered such truth as each had; he had united these individual truths in a harmonious whole, which they took asunder, trying, as some medical sects

do to-day, to build a house with a single brick. Malarial fever is known to occur sometimes in puerperal women, and within a few years a question of priority in its description has been mooted relating to two distinguished American physicians. But the disease was most accurately described in the beginning of the present century by Oslander, and by Torti at a still earlier date. I believe we must go back very much farther, finding the first reference to the disorder in Hippocrates: certainly he has described a disease now known as 'puerperal septicæmia. Littré has shown that this man, whom Galen termed the greatest of physicians and the first of philosophers, observed facts more than 300 years B.C. which have been re-discovered in our day. Thus, in "the Epidemics" he describes a disease characterized by cough, which was often followed by paralysis: this disease was diphtheritic angina, sometimes simple angina, as shown by Gubler and Trousseau. For twenty-two centuries the connection between angina and paralysis was not recognized. According to Laennec, Hippocrates furnishes the germ of auscultation.* He describes paralysis of the veil of the palate accompanying paralysis of the face; lesions of the right side of the brain causing paralysis of the opposite side of the body; muscular atrophy following paralysis; erysipelas of the throat complicating erysipelas of the skin; gangrenous erysipelas; hydatid cysts of the lung.

The character and work of this wonderful man have thus been summed up:† a man grave, modest, wise, charitable, careful of the dignity of his art, avowing his frequent powerlessness; a sagacious observer, endowed with exquisite medical sense, judging phenomena in their connection, he assured to medicine a form which has triumphed over the ages.

But, further, the genius of Hippocrates made known what Chauffard‡ eulogized as the traditional truths of medicine. These primordial truths are the autonomy of life, the unity of existence, its spontaneity, and its own finality. These principles were the soul of Hippocratic medicine; they animated it, gave it life, and, under their inspiration, though the anatomy and physi-

* "Physicians who understand percussion and auscultation have half of medicine and two-thirds of diagnosis."—*Darëmborg*.

† *Revue des Deux Mondes*, 1883.

‡ *Des Vérités traditionnelles en Médecine*.

ology of the day were in almost hopeless infancy, a body of medical doctrine, a system of medical science, was formed. From age to age, through all the development of the science, these truths, the first views because they are first in splendor and power, have remained in some way immutable, reappear with increasing power, lifted above all strifes, all vanishing opinions of the day, receiving a sovereign authority by common consent, transmitted from master to master, from teaching to teaching.

Medicine is not only scientific, but it is progressive; onward is ever the voice of its genius and the example of its teachers and disciples. The progress made in the past fifty years is but faint prophecy of that which will be made in the next fifty, that which hath been but the earnest of that which shall be, for the scientific spirit is everywhere quickened, the means for scientific research constantly increased and improved, the great army of workers becoming larger, and the facilities for intercommunication and for interchange of thought so great. It seems a sad thought that a successful medical book rarely lives more than twenty years; but the fact is a striking testimony to the rapidity of medical progress. How the words of our great master come to us with their simple majesty, and yet almost with the sadness of a threnody: Life is short; art is long; the occasion fleeting, experience fallacious, and judgment difficult.

The very fact that so much remains to be discovered in medicine makes it one of the most inviting subjects of study, "for the sciences always studied with keenest interest are those in a state of progress and uncertainty; absolute certainty and completion would be the paralysis of any study."

Honest pleasure and just pride in discovery await the diligent medical student. Read Aselli's account of the joy he had when he discovered the lymphatics. Think of the undying glory which belongs to the name of Harvey from his discovery of the circulation of the blood, a discovery which at first was denied by many of the physicians of his day, but gradually gained acceptance. Strange, too, to say, one of the most learned of American physicians, the late Dr. John Redman Coxe, of this city, published a work to show that of all the ancients and moderns Harvey had least to do with the discovery which has made his name immortal.

Sometimes the zeal for discovery has been so great that a false fact has been found, and physicians have disputed the question of priority: thus, two* of the profession in the seventeenth century quarrelled as to which was the first to find an acid in the blood.

Important as are discoveries in anatomy and in physiology, those discoveries which are directly applicable to the prevention of disease, such as vaccination, or for the immediate relief of pain, such as the use of anæsthetics, adding at once to the power of medical art, seem the more important. The word "art" is probably derived from the Greek *ἀρετή*, signifying *goodness, excellence, power, force*; it is, indeed, in medicine its practical goodness, excellence, power, force. Increase in medical science is the enlargement of medical art. Science, knowledge organized in a system, a body of truth, reasons, but art acts; science has laws, art has rules; science does head-work, art hand-work; science asks *why*, art knows *how*: in medicine the one is the necessary complement of the other.

In one respect the medicine of to-day is probably inferior to that of Galen's time, the inferiority being in the number of specialties. Then there were not only oculists, lithotomists, herniotomists, and others, but also doctors who did nothing but bleed, some from artery, others from vein, and doctors who limited their practice to giving clysters. If the last specialty is revived in our day, those devoted to it would doubtless take the name of *clysterodidomatists*. Ah, how the length and euphony of that word, which can be rolled as a sweet morsel in the mouth, and which one speaks so trippingly on the tongue, *clysterodidomatists*, would excite the just envy of ophthalmologist and gynæcologist, who have so greatly enriched medical language with sesquipedalian and euphonic Greek compounds!

The genius of medicine is catholic. This catholicity is evident, first, in the physician's comprehending the entire nature of man, and thus understanding his true character. To the mere physiologist, man is simply a living organism, with machinery working not unlike that of a monkey or a dog or some other inferior animal. The psychologist tells

* Viessens and Chiras.

us, in the words of Phavorinus, which were written upon the walls of Sir William Hamilton's lecture-room in the University of Edinburgh: On earth there is nothing great but man; in man there is nothing great but mind. The divine has his attention directed especially to man's moral nature, and seeks to bring it under the control of the highest motives and the most sacred influences. The political economist sees in man either producer or consumer; the legislator sees him the subject of poll-tax, if he be a man, but, if he be a woman, only a promising candidate for the burden and responsibility of a poll-tax, which then, in the belief of those who are not yet educated up to the advanced thought of the times, would be a very great poll evil. The poet, the novelist, the philosopher, each has his ideal man, and generally this ideal is very different from the actual man as the physician knows him. The doctor comprehends the three-fold nature of man,—man intellectual, moral, physical,—and thus comes to a true anthropology. He sees him, not in the framed and flattering picture of the artist, not arrayed in the clothing of social conventionalism, but without artificial adornment, and stripped of all disguise; he sees him at all times, in all places, in all circumstances; he knows the glory and the shame, the power and the weakness, the valor and the cowardice, the goodness and the wickedness, the selfishness and the self-sacrifice, the virtue and the vice, the joy, the hope, the gratitude, the love and the despair, the hate, the ingratitude, the sin and the sorrow, of this human nature.

The genius of medicine is catholic as to its creed. From Hippocrates on, true medicine has lived despite the work of system-makers and the defection of sects. Theurgic medicine, dogmatism, methodism, empiricism, humorism, pneumatism, iatro-mechanism, iatro-chemicism, vitalism, animism, no more did it permanent harm than can any of the unnamed pathies of the day.

"Like clouds that rake the mountain-summit,
Or waves that own no curbing hand,
How fast has system followed system
From sunshine to the sunless land!"

A whole truth, a half truth, has sometimes been made the foundation of a theory of a school, while the great body of medical verities was ignored. How many false

facts, too, as well as false theories, have been brought forward in medicine! Think of so able a man as Van Helmont believing and telling this story: A citizen of Brussels, having lost his nose in a combat, consulted a surgeon named Tagliacozzi. The latter, to cure the deformity, took a flap from the arm of a domestic, and the patient returned home. Thirteen months after, he was suddenly surprised by finding his nose becoming cold and immediately mortifying. How did this happen? After many lamentations and inquiries, it was learned that the domestic from whose arm the nose had been borrowed died at the moment the organ became cold. Think, too, of the illustrious Sylvius, compelling his patients to drink from one hundred and fifty to two hundred cups of tea every day. Fortunately, this practice did not prevail in 1774 in this country, when patriotic Americans were emptying the Chinese leaf by the ship-load into the sea.

Belonging to the same century as Sylvius, we have the illustrious Descartes proclaiming that man and all animals are mere automata, machines, and anticipating Professor Huxley's comparison of a man to a clock. Descartes was more generous than some who have adopted his automatic theory, for he allowed man a soul, seating it upon the pineal gland, like an English sparrow perched on the top of a telegraph-pole.

As Professor Huxley* has so highly commended his theory of automatism, let me quote a distinguished physician's† general estimate of his contributions to medicine: "Descartes introduced into physiology, and maintained in anatomy, more new errors than he destroyed old. He was the parent of the worst part of the iatro-chemical school, and the Cartesian physicians were generally very bad physiologists and only moderately good anatomists."

Descartes denied mind to animals; they did not feel any more than the plant feels the warmth of the sun or the chill of the frost; and thus vivisection was encouraged. He was himself a vivisector, and his example was followed eagerly by the recluses of Port-Royal, who made the following a syllogism of their logic: No matter thinks: every soul of beast is matter: therefore no soul of beast thinks. I would rather take my lesson in the treatment of animals from

* Address before the International Medical Congress, 1881.
† Daremberg.

Coleridge's "Ancient Mariner" than from Descartes :

"He prayeth well who loveth well
Both man and bird and beast."

The genius of medicine is catholic in its relations to science, to philosophy, and to social interests, and is one of the most important factors in the progress of civilization. But these topics can only be suggested, not enlarged upon.

Medicine is catholic in its practice. The physician is ready to relieve the poor as well as the rich, the mean as well as the noble: the cry of suffering, no matter whether it comes from hall or hovel, from virtue or vice, from learned or ignorant, is his call to duty. Hippocrates expressly directed that the physician sent for by two patients, one poor and the other rich, should go to the former; and the illustrious Bayle attended to poor clients, spending upon them in the latter years of his life a large part of that which he had accumulated by practice, saying that the rich could always get doctors. When an urgent call to the sick comes, the physician rarely thinks of his fees, but, if possible, goes at once. However, our charities for the relief of the sick poor have become so well organized, hospitals and dispensaries abounding where the best professional services can be had gratuitously, that there is less demand for the sacrifice inculcated by Hippocrates and practised by Bayle and so many others.

The genius of medicine is beneficent. It is not necessary before an audience so largely professional as this to argue that medical agents have power to assist the natural course of certain diseases to recovery, to shorten the duration of others, to arrest immediately still others, and to lessen and remove physical suffering. Inexorable death claims us all at last as victims, but his coming may be delayed, life lengthened, by the physician's art. The fact that quite a million of men, and hundreds of women, are engaged in the practice of medicine is proof that there is need for them.

Not only is the beneficence of medicine manifested in the cure of disease, but in its prevention. Sanitary science, preventive medicine, has rendered impossible those terrible epidemics which in past centuries ravaged the great centres of population. The sanitary state of a people is the criterion of their civilization.

While the most important sanitary work

belongs to health officers, to the medical members of sanitary boards, and to physicians to public institutions, yet in private practice the opportunities and the demand for this work are great. The office of family physician, that position held by the great majority of the profession, brings more happiness where the medical adviser is sincerely respected, trusted, loved, than public honors or great wealth, and offers abundant opportunities to prevent disease and to promote health. Moreover, how much the family physician can do to set lives right morally as well as physically; to allay social discord; to correct misunderstandings; to comfort the sorrowing; to give garments of praise for the spirit of heaviness; to rouse a slumbering will; sometimes to reclaim the profligate, enforcing the highest lessons of virtue from the penalties of disease; in short, to make men, women, and children healthier, happier, better! Oh, what infinite sympathy the physician learns to exercise,—the loving charity that must be his, forbearing harsh judgment and stern reproach, as he knows the frailties and the follies, the sins and the sorrows, of mortals!

Knowledge and love are necessary for this priestly calling. Hippocrates declared that ours was the most noble of arts, and that we must love man if we would exercise it aright.

Very justly, too, does he speak of the incompetent physicians of his day—who, of course, were relatively much more numerous then than now—as being like the figures which are introduced in tragedies; for, as they have the shape and dress and personal appearance of an actor, but are not actors, so, also, physicians are many in title but very few in reality.

The genius of medicine is heroic. The heroism of physicians has sometimes come from their love of science, but more frequently its source has been conscience and philanthropy. To them medicine is alike a code of morals and a mission of love. Doctors have inoculated themselves with the poison of specific disease, in some cases to study its effects, in others to allay the fears of hospital patients. On all the battle-fields, where masses of men are hurled against each other for the destruction of human life, the physician goes to save life. In hospitals, where contagious epidemics are rife, he makes his way, with never a thought of his own

safety if he can save others. When the pestilence rages in some of our Southern cities, and all who can flee from its terrors, physicians not only remain to combat the disease, but, if need be, a brave army of volunteers go to their help, laboring with them, and in many instances dying with them. The Church has its noble army of martyrs embalmed in perpetual loving remembrance. Medicine has its army of martyrs, whose names should never perish.

How many a surgeon, after performing tracheotomy in a case of diphtheria, has found the tube obstructed, his patient in peril of instant death, and has applied his mouth to the tube and removed the obstruction, saving his patient, it may be, but killing himself! When the Alabama was hopelessly disabled by the well-directed shots of the Kearsarge, the gallant surgeon, Lewellyn, got his wounded men in the only two boats left, but, though urged, refused to enter either of them, lest by overloading the safety of his patients might be imperilled, and went down with the ill-fated ship to sudden death, but to an immortal memory. It is needless to multiply cases: the history of medicine is full of instances where the physician has sacrificed himself for the good of others. Does any one suggest that Galen refused the request of Marcus Aurelius to accompany the army against the Germanic tribes, and that he ran away from Rome because of the plague? As to the first, possibly Galen had no taste for military surgery, and he wanted to finish in the quietness of his Roman home some one of the three or four hundred volumes he wrote. As to the second charge, running away from the plague, who knows but that was a campaign lie? The Greek doctors at Rome said all sorts of naughty things about Galen, scarcely scrupled at any means in their efforts to break him down, and, as probably some know, medical campaigns even in this day occasionally fail in always giving illustrations of the love of truth characteristic of George Washington.

Nevertheless, I am afraid the case against Galen* is too strong to admit of excuse: it can only be said that his conduct was

quite exceptional: the great majority of the profession meet disease rather than run away from it, risking their lives bravely and cheerfully if thereby they can save the lives of others.

Finally, the genius of medicine is reverent. This human body even in its dumb dissection speaks of power and wisdom that no merely human hypothesis can explain. Even conceding Haeckel's assertion of spontaneous generation as the beginning of life on this earth, and from this starting-point tracing the evolution of man, it is utterly inconceivable that such result should be accomplished without a directing mind. However, this opens too wide a discussion for the present occasion, though even Dr. Maudsley, in his recent work upon "Body and Will," says, in referring to the ovum, "in its nature is inscribed the architectural *plan* or *form* of its development," and one naturally asks, "Who made that plan?" It is vain to attempt to get rid of the notion that a product implies a producer, that houses and books, watches, and all wonderful pieces of machinery, never make themselves, but that they are the thoughts of men given expression and form; the common sense of men revolts at the suggestion that this world, with its flora and fauna, is such an infinitely improbable accident as could be made by a blind evolution. If, says Voltaire, a watch proves a watchmaker, a palace an architect, how is it that the universe does not demonstrate a supreme intelligence? What plant, what animal, what element, what star, does not bear the imprint of Him whom Plato called the eternal Geometer? It seems to me that the body of the least animal demonstrates a profoundness and unity of design which ought to enrapture us with admiration.

It is useless for any one to tell us that monism and evolution explain the mysteries of organic life, and of man, the highest in earth's creation; we must still believe in design, and in an intelligent designer, no matter how near to or remote from his work, no matter whether the chain of second causes has a dozen or a million links.

In the study of anatomy and physiology the evidences of design, of contrivance, are apparent to every thoughtful mind. Let me suggest from the almost infinite number a few: some of the veins in the human body have valves, others, as the visceral veins and the vena portarum, are

* Dechambre, in his interesting article upon *Déontologie*, in the "Dictionnaire Encyclopédique des Sciences Médicales," suggests that Galen went away to escape the hatred of the Greek doctors. The plague of lying lips may be worse than any bodily plague, and the pestilent breath of the slanderer, who tries to traduce any one who is more prominent than he, may be feared more than physical disease.

valveless, and the law, as stated by Marey, is that those veins do not have valves which are not subject to localized and intermittent pressure. This difference cannot result from chance. The walls of the left ventricle of the heart are much thicker than those of the right; but in the foetus the walls are of equal thickness: a study of the difference between the intra-uterine and extra-uterine circulation gives a reason for this difference. Why should the sebaceous glands of the foetus be so active that its body is more or less covered with fatty matter? Because, immersed in the fluid it is, there would be probably a dangerous osmosis from its blood, and it would present at birth a shrivelled, wrinkled appearance, like one's hands after having been kept in water for some time. In the latter part of pregnancy the fibrin undergoes a wonderful increase. Why? As the most important safeguard against post-partum hemorrhage. But I cannot continue these illustrations. Observe, think, in the course of your professional studies, and you will find abundant reason for faith in final causes.

The great founder of pathological anatomy, Morgagni, said, "The more I study anatomy, physiology, pathology, and pathological anatomy, the better I know God, the soul, and its immortality."

I believe that whether we take medicine as a study or as a practice, or the examples of the most illustrious men in the profession, we may justly say that the genius of medicine is profoundly reverent. "The grand voices of the profession unite with the grand voice of nature to affirm the existence and the attributes of a supreme legislator, that of our spiritual nature, of the faculties which distinguish it, and the certainty of our future destiny."

TRANSLATIONS.

A NEW URINARY TEST.—A solution of sulphodiabenzole under certain conditions gives a characteristic reaction with the urine in several pathological conditions. According to Ehrlich, the solution is prepared by acidifying 500 C.c. of water with 30–50 C.c. of pure sulphuric acid, and then adding sulph-anilinic acid until an excess remains undissolved, and then a few grains of nitrate of soda in solution in

water. In summer this solution may be kept for two or three days, while in winter it remains unaltered for five. If equal amounts of this reagent and urine from a case of typhoid fever are mixed, and then a little ammonia added, an intense scarlet red is developed. Normal urine does not produce this result. With the exception of pulmonary phthisis, this reaction is nearly always associated with the febrile state, while its appearance is especially constant in typhoid fever. Penzoldt has also experimented with this reagent, and has obtained the characteristic reaction in diabetic urine, even when the urine contains only one part per thousand of sugar. —*Centralb. f. d. Med. Wissen.*, August 4, 1883.

THE TREATMENT OF IRREDUCIBLE LUXATIONS.—In an interesting article on this subject, Rosenmeyer states that in most cases of irreducible luxation of the shoulder a high degree of usefulness may be restored to the joint by the constant and prolonged use of passive movements, massage, electricity, and warm baths; but when the mobility of the false joint is very slight, when great pain is caused by pressure on the nerve, or when the muscles are commencing to atrophy, arthrotomy is to be recommended. If the dislocation is of very old standing and extensive changes have taken place in the joint-socket, then resection of the head of the humerus should be performed. In the case of the elbow-joint, the results obtainable by passive movements, subcutaneous section of muscles, tendons, adhesions, etc., are far inferior to those which follow the resection of the joint.—*Centralblatt für Chirurgie*, August 4, 1883.

AN IMPORTANT MODIFICATION OF THE CATHETER.—In a communication to the *Berliner Klinische Wochenschrift*, F. Hüpeden calls attention to the danger of introducing infectious material into the bladder in catheterization, on account of a difficulty experienced in cleansing the ordinary catheter. The end of the catheter beyond the vesical opening forms a chamber for the accumulation of organic material, which is very difficult to dislodge. The recommendation is made that this end be filled up with metal, so that the danger of causing putrefactive changes in the residual urine in the bladder may be avoided, with ordinary care.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, OCTOBER 20, 1883.

EDITORIAL.

OUR EDUCATIONAL NUMBER.

IT has long been the custom with some of the leading European medical journals to devote at least one issue annually to the systematic consideration of medical education, giving especial attention to the *personnel* of the various local schools, with such information as to lectures, fees, requirements, etc., as experience had shown was of the most interest to prospective or actual students. Such issues, known as the "students' number," or "educational number," have been much sought after on account of the important information which they contain. For this reason, of late years, similar reports have been published by some of our prominent American contemporaries, notably the *Boston Medical and Surgical Journal*, and recently the *New York Medical Journal*.

Realizing the impossibility of giving any just and satisfactory report of the eighty-nine regular medical colleges in the United States now in active operation, in the space at our command, or even of the sixty-three of them which have received the endorsement of the Illinois State Board of Health, we have in our present issue, without attempting a complete analysis of the subject of medical education in the United States, sought to improve the opportunity offered by the publication of the opening addresses at our two leading medical schools, to communicate some interesting information upon medical education sent us by some of our correspondents in a few only of the principal medical centres of this country.

The "students' number" of the *London Medical Record*, for September, contains

valuable material for reference concerning foreign medical schools, but much more information of the kind desired by those who wish to visit or study abroad may be found in a little work just published by William Wood & Co., entitled "A Guide to American Medical Students in Europe," written by Prof. Hun, of Albany. For those desiring a complete, systematic comparison of American medical schools we recommend a perusal of a pamphlet recently issued by the Illinois State Board of Health, which is a very valuable report on "Medical Education and the Regulation of the Practice of Medicine in the United States and Canada." It contains a summary of the laws governing the practice of medicine in the different States (alphabetically arranged for easy reference), together with well-digested information concerning the several colleges, which gives it permanent value. From it we learn that there are eighty-nine colleges now in existence in the United States, of which fifty-five exact a preliminary education as a condition of matriculation, and fifteen require attendance upon three full courses of lectures before graduation. There have been, also, several post-graduate schools started within a few years. These figures are not without encouragement to advocates of higher medical education.

We have departed somewhat in this issue from the usual arrangement, in order to publish simultaneously the opening lectures of Professors Stillé and Parvin. By the majority of our readers we believe that the able and earnest utterances of these distinguished teachers and authors, who have contributed their addresses to our pages, will be read with interest and advantage.

Medical education in this country of the colleges is now in a transition stage, but the promise of advancement is seen on every hand. In the inevitable struggle for life it is evident that, if the medical pro-

fession will but do its part, the survival of those colleges only that are most fit to be intrusted with the education of future physicians will be assured. We note with pleasure the evidences of real progress that are seen on every side.

THE ATTITUDE OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY TOWARDS WOMEN CANDIDATES.

THE Philadelphia County Medical Society, at its last business meeting, again rejected women candidates for membership, although they had been properly recommended by the Board of Censors. Inasmuch as the American Medical Association recognizes the right of women practitioners to belong to the county medical societies, and receives them as delegates at its annual sessions, it would certainly appear that the women physicians of Philadelphia County cannot lawfully be deprived in this manner of their right of representation and membership in the National Association, even to gratify the caprice or prejudice of certain individuals.

The Philadelphia County Medical Society, moreover, is a branch organization of, and subordinate to, the Pennsylvania State Medical Society, which admits women delegates: how, then, can it assume to represent *all* the regular medical practitioners of Philadelphia County when it persistently refuses to receive a certain proportion of them as members? The society of any county must either faithfully represent all regular physicians practising in its territory, or yield its place to a new society that will do so. It is acknowledged to be the duty of all regular physicians in good standing in the profession to belong to their county or district medical society, and if approved by the Censors *they have a right to admission*, and no man, or combination of men, can justly deny them this right. It has been con-

ceded that the candidates referred to were eligible under the By-Laws of the Society, and had a right to admission established both by precedent and by law: can the Society, therefore, afford to stultify itself by continuing its present attitude towards women candidates for membership?

NOTES FROM SPECIAL CORRESPONDENTS.

MEDICAL EDUCATION IN PHILADELPHIA.

THE problem of medical education, in which should be included the development and cultivation of those faculties required in the true physician, as well as the ordinary technical instruction, has been solved by Philadelphia schools better than any other medical colleges on the continent, if the number of graduates and the position filled by them in the American medical profession may be taken as a fair criterion. An examination into the present methods of teaching shows the result of an evolution which has steadily kept up with, if indeed now it is not really ahead of, the actual requirements of the community. In discussing heredity in his recent work, Francis Galton has stated it as a fact that our culture has advanced beyond our mental capacity; and we may certainly accept this as applied to medical culture, for the resources of the art of medicine are at the present day far beyond the capacity of the general public to understand or to appreciate. Without pursuing this subject, let us see how Philadelphia colleges are equipped and manned for their great and responsible work.

THE UNIVERSITY OF PENNSYLVANIA, MEDICAL DEPARTMENT.

The Department of Medicine of the College of Philadelphia, as it was originally called, was organized in 1765: it held its first Commencement in 1768, and has graduated classes each succeeding year, the total number of graduates now exceeding ten thousand.

The Faculty embraces eleven chairs, which are filled as follows:

FACULTY.

- JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
- HENRY H. SMITH, M.D., Emeritus Professor of Surgery.
- RICHARD A. F. PENROSE, M.D., LL.D., Professor of Obstetrics and Diseases of Women and Children.
- ALFRED STILLÉ, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
- D. HAYES AGNEW, M.D., LL.D., John Rhea Barton Professor of Surgery, and of Clinical Surgery.
- WILLIAM PEPPER, M.D., LL.D., Professor of Clinical Medicine, also Provost of the University and *ex-officio* President.
- WILLIAM GOODELL, M.D., Professor of Clinical Gynecology.
- JAMES TYSON, M.D., Professor of General Pathology and Morbid Anatomy, and Secretary of the Faculty.

HORATIO C. WOOD, M.D., Professor of Materia Medica, Pharmacy, and General Therapeutics.
 THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
 JOHN ASHHURST, JR., M.D., Professor of Clinical Surgery.
 HARRISON ALLEN, M.D., Professor of Physiology.

The Faculty is assisted by the following

DEMONSTRATORS AND LECTURERS.

CHARLES T. HUNTER, M.D., Demonstrator of Anatomy.
 ROLAND G. CURTIN, M.D., Lecturer on Physical Diagnosis.
 CHARLES K. MILLS, M.D., Lecturer on Mental Diseases and Electro-Therapeutics.
 J. HENRY C. SIMES, M.D., Demonstrator of Pathological Histology.
 ADOLPH W. MILLER, M.D., Lecturer on Materia Medica and Pharmacy.
 JOSEPH G. RICHARDSON, M.D., Demonstrator of Normal Histology.
 ROBERT MEADE SMITH, M.D., Demonstrator of Experimental Physiology.
 JOHN MARSHALL, M.D., Nat.Sc. D., Demonstrator of Practical Chemistry.
 BENJAMIN F. BAER, M.D., Demonstrator of Clinical Gynecology.
 ELLIOTT RICHARDSON, M.D., Lecturer on Clinical and Operative Obstetrics.
 EDWARD T. BRUEN, M.D., Demonstrator of Clinical Medicine.
 J. WILLIAM WHITE, M.D., Demonstrator of Surgery, and Lecturer on Venereal Diseases.
 HARRY R. WHARTON, M.D., Demonstrator of Clinical Surgery.
 JOHN B. DEEVER, M.D., Demonstrator of Osteology and Syndesmology.
 HENRY F. FORMAD, M.D., Demonstrator of Morbid Anatomy, Assistant Demonstrator of Pathological Histology, and Lecturer on Experimental Pathology.
 EDWARD T. REICHERT, M.D., Demonstrator of Experimental Therapeutics.

The course of instruction consists each year of a regular winter term of twenty-eight weeks' duration from the first Monday in October, which is obligatory, and a three weeks' preparatory course, and a spring course of eleven weeks, attendance upon which is not required. The curriculum is a graded one of three years' duration, but a four years' course is encouraged by the Faculty. Examinations are held at the end of each term. The requirements for admission are either the possession of a collegiate degree, a certificate from a high school, one from a board of managers of a county medical society, or a preliminary examination.* For graduation the candidate must be twenty-one years of age, of good moral character, and must have attended three full courses of lectures, passed the final examination, and written an accepted thesis. Tickets of other regular colleges are recognized, and graduates of other medical colleges are admitted to the three years' course without examination. Fees are five dollars for matriculation, paid once; and one hundred and fifty dollars for each course of lectures, including laboratory and dissection. No graduation fee.

Concerning the methods of study, we learn that during the first and second years much

of the student's time is occupied with practical work in the various laboratories, of chemistry, pharmacy, osteology, histology, and pathological histology, and in dissection; but throughout the second and third years he is required to attend the general medical and surgical clinics at the University and Philadelphia hospitals, while special clinical facilities are provided for the third year. In this year each student receives bedside instruction in clinical medicine and surgery, in physical diagnosis, and in gynecology. Opportunities are afforded for the practical study of diseases of the eye, ear, throat, and skin, and for acquiring proficiency in the use of the various instruments employed in their treatment. For this purpose the third-year class is divided into sections of convenient size, each of which receives direct personal instruction in the various practical subjects above mentioned. In the fourth year, recently organized to go into operation with the session of 1883-84, and upon which attendance is voluntary, the instruction is almost purely practical in character.

A prominent feature of the present curriculum is systematic laboratory work in the fundamental medical sciences, as well as the personal teaching of each student in practical subjects of the greatest importance, such as physical diagnosis, clinical medicine, clinical surgery, and clinical gynecology. Students of the Medical Department of the University are now not only trained in the theory of medicine, but are also taught to perform chemical, pharmaceutical, and microscopical manipulations, to diagnose and treat medical and surgical diseases, and to recognize their post-mortem appearances. Exclusively didactic teaching has been universally abandoned in every branch of scientific and technical education, save the medical. Therefore, in establishing the present method, the trustees and the medical Faculty of the University felt that they were only adopting one which, in other departments of science, had produced the most valuable fruits. This result shows that, sooner or later, medical teaching in this country must be conformed to the system which has long been recognized as the only one suitable in the great medical centres of Europe.

The secretary of the Faculty, Prof. James Tyson, in reply to a request for information, kindly states that "the first-year class will certainly number one hundred and forty, which is larger than it has ever been since the inauguration of the three-years graded curriculum. Last year it numbered one hundred and fifteen. The year before we put on the admission examinations, it reached one hundred and thirty-seven; the session immediately following the admission examinations it fell to one hundred and ten; the next, to ninety-eight; the next, which was last year, it rose to one hundred and fifteen, and this

* Examinations for admission will be held annually hereafter during the first week in September in the cities of Boston, Mass., Rochester, N.Y., Raleigh, N.C., Columbia, Tenn., Atlanta, Ga., Mobile, Ala., Cincinnati, O., Chicago, Ill., Detroit, Mich., St. Louis, Mo., St. Paul, Minn., and San Francisco, Cal. This provision is made solely for the convenience of the student. He can, of course, be examined in Philadelphia if preferred.

year to one hundred and forty." He adds, "This is increase quite rapid enough, but, if it were not for the expenses of the course, I am sure there would be many more. The increasing of the term to seven months seems to have had no effect in throwing us back." A voluntary fourth-year class has been formed this year. The Towne Scientific School offers a good preparatory course for those who intend taking the medical degree.

The present course opened October 1, by an address by Prof. Stillé (see page 41); the term will end April 12, 1884.

A course has also been organized for post-graduate instruction.

The post-graduate instruction in connection with this University for the year 1883 is divided into three terms, as follows:

- (1) From January 2 to March 1, inclusive.
- (2) From April 9 to June 9, inclusive.
- (3) From October 29 to December 24, inclusive.

The following subjects are taught:

CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS, by Prof. Pepper and Dr. Bruen.

RENAL DISEASES, WITH PRACTICAL EXAMINATION OF URINE, by Prof. Tyson and Dr. Formad.

NERVOUS DISEASES AND ELECTRO-THERAPEUTICS, by Prof. Wood and Dr. Mills.

CLINICAL SURGERY, by Prof. Ashhurst and Dr. Wharton.

OPHTHALMOLOGY, by Prof. Norris and Dr. Risley.

DERMATOLOGY, by Prof. Duhring.

OTOLOGY, by Prof. Strawbridge.

GYNÆCOLOGY, by Prof. Goodell and Dr. Baer.

OPERATIVE AND GENITO-URINARY SURGERY, WITH VENEREAL DISEASES, by Dr. White.

CLINICAL AND OPERATIVE OBSTETRICS, by Dr. Elliott Richardson.

LARYNGOLOGY, by Dr. Seiler.

DISEASES OF CHILDREN, by Dr. Start and Dr. Keating.

The teaching consists in bedside and dispensary lessons, in the practical examination of patients, and in the use of instruments of precision in the diagnosis and treatment of disease, to classes composed of graduates only. There are two classes of graduates to whom these courses are adapted: first, recent graduates, and second, those who have been for some years engaged in practice at a distance from medical centres. To the latter, the review afforded by such practical courses has been found peculiarly advantageous. From one to three hours weekly are devoted to these objects in each of the branches named. In clinical medicine one hour weekly will be devoted to a clinical conference.

In addition, the classes are permitted to attend the general and special clinics of the University and such didactic lectures as do not occur in the hours devoted to post-graduate instruction.

In addition to the above courses, the following are also given:

PRACTICAL PHYSIOLOGY, by Dr. ROBERT MEADE SMITH. Systematic Instruction in Experimental Physiology and Experimental Therapeutics, and the superintendence of Original Investigations.

MEDICAL CHEMISTRY, by Professor WORMLEY and Dr. MARSHALL. Including Toxicological and Medico-Legal Studies, Investigation of Blood-Stains, and Physiological Chemistry.

HISTOLOGY AND PATHOLOGY, by Dr. H. F. FORMAD.

Two courses: I. Normal and Pathological Histology, including Microscopic Technology; the opportunity of witnessing and making Post-mortem Examinations. Winter and spring months. II. Experimental Histology and Experimental Pathology.

The fees for this course can be ascertained on application. There is no expense attached to the course of preliminary lectures.

There is also an Auxiliary Department of Medicine, distinct from the others, which supplements the winter lectures by a course given during the spring months on certain collateral branches of science. Graduates of this school, after attendance upon two full courses of lectures and examination, receive the degree of Bachelor of Science.

Its Faculty consists of

JOHN J. REESE, A.M., M.D., Professor of Medical Jurisprudence and Toxicology.

SAMUEL B. HOWELL, M.D., Professor of Mineralogy and Geology.

JOSEPH T. ROTHROCK, B.S., M.D., Professor of Botany.

JOSEPH G. RICHARDSON, M.D., Professor of Hygiene.

ANDREW J. PARKER, M.D., Ph.D., Professor of Comparative Anatomy and Zoology.

A Department of Philosophy also exists, with the following corps of instructors:

E. OTIS KENDALL, LL.D., Professor of Mathematics, and Dean of the Faculty.

JOSEPH LEIDY, M.D., LL.D., Professor of Zoology.

J. PETER LESLEY, LL.D., Professor of Geology.

J. I. CLARK HARE, LL.D., Professor of Law.

REV. ROBERT E. THOMPSON, A.M., Professor of Political and Social Science.

FREDERICK A. GENTH, Ph.D. (Marburg), Professor of Inorganic Chemistry.

SAMUEL B. HOWELL, M.D., Assistant Professor of Geology.

GEORGE F. BARKER, M.D., Professor of Physics.

GEORGE A. KENIG, Ph.D. (Heidelberg), Professor of Mineralogy.

HUGH A. CLARKE, Professor of Music.

JOSEPH T. ROTHROCK, B.S., M.D., Professor of Botany.

THEODORE G. WORMLEY, M.D., LL.D., Professor of Organic Chemistry.

ANDREW J. PARKER, M.D., Ph.D., Assistant Professor of Zoology.

MORTON W. EASTON, Ph.D., Professor of Comparative Philology.

— Professor of History,

— Professor of Philosophy.

The Faculty of Philosophy has recently been organized for the supervision of advanced studies in the several departments of literature and science. The degree conferred upon recommendation of this Faculty is that of Doctor of Philosophy. The courses, which cover a period of at least two years, are open to graduates in any department of this or like institutions, and to others who can pass a satisfactory examination.

Among the other departments of the University may be mentioned a Dental Department, which is in a flourishing condition. Its Faculty consists of

CHARLES J. ESSIG, M.D., D.D.S., Professor of Mechanica Dentistry and Metallurgy.

EDWIN T. DARBY, M.D., D.D.S., Professor of Operative Dentistry and Dental Histology.

JAMES TRUMAN, D.D.S., Professor of Dental Pathology Therapeutics, and Materia Medica.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.

HARRISON ALLEN, M.D., Professor of Physiology.

THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry.

ROBERT HUEY, D.D.S., Lecturer on Operative Dentistry.

The buildings of the University are located

upon elevated ground, and occupy a commanding position upon the west side of the Schuylkill River; they consist of the Departments of Arts and Towne Scientific School, in addition to the Medical and Dental buildings, and the laboratory, and a large general hospital.

THE JEFFERSON MEDICAL COLLEGE.

The Jefferson Medical College was originally the medical department of the Jefferson College at Canonsburg, Pennsylvania, which was a university, but is now defunct, the medical department having survived, and having succeeded to the rights and privileges of the parent institution. In conformity with this, it usually confers, at the annual Commencement, honorary degrees of Doctor of Laws or Doctor of Divinity through its board of trustees, but no honorary degrees in medicine are given. The first class was graduated from this institution in 1827, and others have been graduated each subsequent year. The total number of graduates is eight thousand one hundred and forty-three.

The curriculum includes an obligatory winter course, extending over twenty-six weeks, with a preliminary session of three weeks, and a spring course of eight weeks, attendance upon which is not required for graduation. The present course began October 1, with an introductory address by Prof. Parvin (see page 51). The Commencement will be held March 29, 1884, after the close of the lectures.

The Faculty of the college, with the subjects lectured upon, are as follows:

SAMUEL D. GROSS, M.D., LL.D., D.C.L. Oxon., LL.D. Cantab., Institutes and Practice of Surgery (Emeritus).
 ELLERSLIE WALLACE, M.D., Obstetrics and Diseases of Women and Children (Emeritus).
 J. M. DA COSTA, M.D., Practice of Medicine.
 WILLIAM H. PANCOAST, M.D., General, Descriptive, and Surgical Anatomy.
 ROBERT E. ROGERS, M.D., LL.D., Medical Chemistry and Toxicology.
 ROBERTS BARTHOLOW, M.D., LL.D., Materia Medica and General Therapeutics.
 HENRY C. CHAPMAN, M.D., Institutes of Medicine and Medical Jurisprudence.
 SAMUEL W. GROSS, M.D., Principles of Surgery and Clinical Surgery.
 JOHN H. BRINTON, M.D., Practice of Surgery and Clinical Surgery.
 THEOPHILUS PARVIN, M.D., LL.D., Obstetrics and Diseases of Women and Children.
 WILLIAM THOMSON, M.D., Honorary Professor of Ophthalmology.
 J. SOLIS COHEN, M.D., Honorary Professor of Laryngology.

DEMONSTRATORS.

WILLIAM S. FORBES, M.D., Demonstrator of Anatomy.
 J. EWING MEARS, M.D., Demonstrator of Surgery.
 G. MASON WARD, M.D., Demonstrator of Chemistry.
 MORRIS LONGSTRETH, M.D., Demonstrator of Pathological Anatomy, and Curator of the Museum.
 COCHRAN McCLELLAND, M.D., Demonstrator of Obstetrics.
 DAN. E. HUGHES, M.D., Demonstrator of Clinical Medicine.
 S. MASON MCCOLLIN, M.D., Demonstrator of Pharmacy and Materia Medica.
 A. P. BRUBAKER, M.D., Demonstrator of Physiology and Histology.

The college buildings are situated on Tenth Street, between Chestnut and Walnut, and

comprise a medical hall, laboratory building, and hospital immediately adjacent. This central position gives to the school many advantages; among them an extensive choice of homes for the student convenient to the college, and proximity to the various business houses with which the student may have occasion to deal, as well as to the Pennsylvania Hospital.

The college building proper contains two large, well-arranged, and well-ventilated lecture-rooms. In the summer of 1881 the main building was remodelled by an extension of the front, by adding a new story, and by constructing new laboratory-rooms. By this extension of the front, the seating-capacity of each lecture-room has been materially increased, and by the addition of another story, new and more commodious dissecting-rooms have been constructed. Large and well-lighted rooms have been provided for practical obstetrics, and for the laboratory of experimental therapeutics and pharmacy, and another with special reference to microscopical work, and for a laboratory of pathological histology and morbid anatomy.

In this building are also contained the extensive and valuable anatomical, surgical, and pathological museums.

The laboratory building, immediately adjoining the medical hall, contains the physiological and chemical laboratories, fully equipped in the materials and instruments of study and research, and also the laboratory for the demonstration of operative and minor surgery.

No preliminary examination or technical proof of preparation for medical studies is exacted; but for graduation three years' study is necessary, with attendance upon two full courses of lectures. The candidate must also be twenty-one years of age, and be of good moral character. Students of dental colleges where full courses of five months' duration are given on anatomy, materia medica, physiology, and chemistry may become candidates after attendance on two such courses and one full course at this college, with another on surgery, practice of medicine, and obstetrics. A similar arrangement is made with students of colleges of pharmacy, except that among the additional branches named must be included anatomy and physiology. The expenses are—for matriculation, \$5; graduation, \$30 (each paid once); lectures, \$140 each session; with dissecting, \$10; other practical courses free. A reduction in the tickets for the course is made to graduates in dentistry and pharmacy.

Attendance upon a third term of lectures, though not obligatory, is encouraged by the Faculty, and is followed by a considerable proportion of the class. No charge is made for the extra course of lectures, and students are permitted to take a partial examination at the end of the second course, thus devoting

the final year to the practical branches exclusively.

A post-graduate course has been inaugurated during the past year, which includes five terms of seven weeks each, and extends from October to May inclusive.

The instructors and subjects taught by them respectively are as follows:

PROF. WILLIAM THOMPSON, Ophthalmology.
 DRS. L. and CHARLES TURNBULL, Otolaryngology.
 DRS. F. H. GETCHELL and J. EWING MEARS, Gynecology.
 DR. J. C. WILSON, Physical Diagnosis, Diseases of the Chest.
 DR. O. H. ALLIS, Orthopædic Surgery.
 DR. MORRIS LONGSTRETH, Normal and Pathological Histology.
 DR. O. P. REX, Diseases of Children.
 DR. J. T. ESKRIDGE, Nervous Diseases.
 DRS. SAJOUX and JURIST, Laryngology.
 DR. J. S. NEFF, Urinary Pathology.
 DR. G. M. WARD, Medical Chemistry.
 DR. S. M. MCCOLLIN, Practical Pharmacology.
 DR. A. P. BRUBAKER, Experimental Physiology.
 DR. J. V. SHOEMAKER, Dermatology.
 DRS. A. K. MINICH and A. R. RYNEAR, Botany, Materia Medica, and Experimental Therapeutics.

All the courses will be demonstrative. The fees for each branch will range from \$10 to \$20.

THE MEDICO-CHIRURGICAL COLLEGE.

This school was organized in 1881, upon a plan which, if carried out in good faith, will go far towards elevating the standard of medical instruction and medical practice in this country. The course of instruction contains the following features: a winter's term, extending over twenty-four weeks; daily quizzes by the professors; a three years' graded course required.

The requirements for admission are a certificate of having graduated at a high school, or of having attended a classical seminary or college for at least a year, or having passed the examination of a board of examiners of a county medical society, or attendance upon the auxiliary literary term, the studies being elements of English literature and Latin, Greek, and natural science. For graduation, besides the usual requirements, the candidate must have attended three regular winter sessions, the last being in this college, and a special course of physical and practical instruction, also given at this college. The present course of lectures began October 1, and will extend twenty-four weeks.

The Faculty is constituted as follows:

GEORGE P. OLIVER, M.D., President.
 WILLIAM S. JANNEY, M.D., Principles and Practice of Surgery and Clinical Surgery.
 GEORGE E. STUBBS, M.D., Anatomy and Clinical Surgery.
 CHARLES L. MITCHELL, Ph.D., M.D., Chemistry, Sanitary Science, and Medical Jurisprudence.
 WILLIAM F. WAUGH, M.D., Principles and Practice of Medicine and Clinical Medicine.
 ABRAHAM S. GERHARD, M.D., Physiology, Pathology, and Clinical Medicine.
 WILLIAM S. STEWART, M.D. (Dean), Obstetrics, Gynecology, and Clinical Gynecology.
 FRANK O. NAGLE, M.D., Materia Medica, Therapeutics, and Clinical Medicine.

THE WOMEN'S MEDICAL COLLEGE OF PENNSYLVANIA.

This college graduated its first class in 1851,

and has continued regularly since that time. The opening lecture of the present course was delivered by the Dean, Rachel L. Bodley, M.D., October 4, 1883. The Commencement will be held March 13, 1884.

The Faculty is constituted as follows:

RACHEL L. BODLEY, M.D., Professor of Chemistry and Toxicology.
 CLARA MARSHALL, M.D., Professor of Materia Medica and General Therapeutics.
 FRANCES EMILY WHITE, M.D., Professor of Physiology and Hygiene.
 ANNA E. BROOMALL, M.D., Professor of Obstetrics.
 JAMES B. WALKER, M.D., Professor of the Principles and Practice of Medicine.
 HANNAH T. CROASDALE, M.D., Professor of Diseases of Women and Children.
 WILLIAM H. PARISH, M.D., Professor of Anatomy.
 WILLIAM W. KEEN, M.D., Professor of the Principles and Practice of Surgery.
 J. GIBBONS HUNT, M.D., Professor of Histology and Microscopy.
 C. NEWLIN PEIRCE, D.D.S., Professor of Dental Physiology and Pathology.
 HORATIO C. WOOD, JR., M.D., Lecturer on Special Subjects.
 EDWARD T. BRUEN, M.D., Lecturer on Pathology.
 CHARLES K. MILLS, M.D., Lecturer on Nervous Diseases.
 LOUIS A. DUHRING, M.D., Lecturer on Dermatology.
 ALEXANDER W. MCCOY, M.D., Lecturer on Laryngoscopy and Rhinoscopy.
 EMILIE B. DU BOIS, M.D., Demonstrator of Anatomy and Instructor in Materia Medica.
 LUCIUS E. SAYRE, Ph.G., Demonstrator of Pharmacy.
 HENRY F. FORMAD, M.D., Demonstrator of Pathology.
 IDA E. RICHARDSON, M.D., Instructor in Practice of Medicine.
 ANNA M. FULLERTON, M.D., Instructor in Obstetrics.
 LENA V. INGRAHAM, M.D., Instructor in Surgery.

This college is contributing materially to the solution of two problems,—the proper qualification of women practitioners for the practice of medicine, and the greater one of higher medical education. It was among the first in the country to lengthen its winter session; it has also adopted an optional three-years graded course, and the Faculty earnestly recommends a four-years course, with annual examinations. The lectures are intended to be on a par with those given in the higher class of medical schools in this country, and unusual facilities are given for laboratory-work and original investigation. This college pursues the plan of giving weekly reviews, or quizzes, on the lectures by regularly appointed instructors throughout the winter course. These examinations constitute a part of the college preceptorship, and are free to every student.

Besides the winter session, a spring course of lectures, of ten weeks' duration, is given.

The requirements for graduation are similar to those of the Jefferson College. The expenses are—matriculation, \$5; lectures, \$105 (each course); demonstrator of anatomy, \$10; clinical, pathological, and pharmaceutical laboratories, each \$10. Graduation fee, \$30.

No information has been supplied by the Dean as to the size of the class.

PHILADELPHIA POLYCLINIC COLLEGE FOR STUDENTS IN MEDICINE.

This institution gives to graduates instruction in the recognized medical and surgical specialties, as well as in hygiene, clinical

chemistry, fracture-dressings, and operations on the cadaver. Its system of teaching is entirely demonstrative and clinical, as it must needs be to meet the wants of practitioners who resort to the medical centres to acquire facility in the use of instruments of precision. The sessions of six weeks enable physicians to leave their practice for but a short time and yet acquire familiarity with methods of diagnosis and treatment in the fields of special medicine. The dispensary of the college, and the out-patient or home department, together with the services of various hospitals, afford opportunities for accurate study of disease. The aim of the college is to supplement the work of institutions for undergraduates by giving those who have attained the position of physician practical knowledge such as can be obtained only by performing, under competent supervision, operations and manipulations on the living subject. Its pupils, after a prescribed course and examination, may acquire the diploma of Fellowship to the Philadelphia Polyclinic and College for Graduates in Medicine, which announces to the public that the holder is not only a Doctor of Medicine, but also acquainted with the advanced specialties of the present age.

The Faculty is constituted as follows:

THOMAS G. MORTON, M.D., Clinical, Operative, and Orthopædic Surgery.
 J. SOLIS-COHEN, M.D., Diseases of the Throat and Chest.
 JOHN B. ROBERTS, M.D., Applied Anatomy and Operative Surgery.
 CHARLES H. BURNETT, M.D., Diseases of the Ear.
 CHARLES K. MILLS, M.D., Diseases of the Mind and Nervous System.
 HENRY LEFFMANN, M.D., Clinical Chemistry and Hygiene.
 ARTHUR VAN HARLINGEN, M.D., Diseases of the Skin.
 EDWARD L. DUER, M.D., Obstetrics and Diseases of Women and Children.
 GEORGE C. HARLAN, M.D., Diseases of the Eye.
 J. HENRY C. SIMES, M.D., Genito-Urinary and Venereal Diseases.
 FREDERICK P. HENRY, M.D., Pathology and Microscopy.
 WILLIAM H. PARISH, M.D., Obstetrics and Diseases of Women and Children.

Philadelphia has about twenty hospitals, nine dispensaries, and thirty-eight other charitable institutions with which infirmaries are connected. Many special branches of medicine and surgery have their distinct institutions, as the Maternity, the Orthopædic, the Hospital for Nervous Diseases, Diseases of the Skin, for Children, etc. Graduates and advanced students desiring to pursue any special branch of medical science, or any of the recognized specialties, have, therefore, admirable opportunities afforded them in these various hospitals, and other public medical institutions.

NEW YORK.

MEDICAL PRACTICE AND MEDICAL TEACHING.

THE cool weather of the fall has again brought life and activity into professional circles here. The hibernating season of our principal practitioners has closed, and their

offices are again filled with patients just returned to the city and wishing to consult on trivial or chronic ills, concerning which they did not care to go to a strange or a country doctor. But reports are frequent of a sickly season out of town, and some of our rural fellows have reaped a rich harvest off the sojourners at our fashionable resorts. Every year a number of these physicians follow their patients to the city with intent to settle here; but the formidable array of shingles upon every block soon frightens most of them away, and those who do venture generally seek a less vigorous competition before the year is out.

The epidemic of typhoid—if, indeed, such did threaten us—has been averted, and new cases now are comparatively few, much to the disgust of the deodorizer, germicide, and disinfectant men, who have flooded the city with their circulars and made large sales on the strength of our Health Board's warning. Its subsidence is probably due to the opening of the flood-gates of our aqueduct and a more abundant supply of water turned on the city. It is broadly hinted that this is due to the appropriation for a new aqueduct having been secured, and that we might have had this increased supply all the time but for political greed. It is to be regretted that such means are necessary to secure such a needed improvement. One aqueduct is not enough for a city surrounded by salt water and containing a million and a half of people: hence it may be said, this time, the end justifies the means.

There is to be an operation in one of the hospitals here before long for extirpation of the kidney, which, judging from the looks of the patient, may add another to the recent successes of that brilliant operation.

The noted Dr. Shine, who for several years has been surgeon to the Elevated Railroads of this city, has been removed to an institution for the insane in this State, and his place filled by Dr. Matthew Field. Dr. Shine was never noted for either his temperance habits or professional etiquette, and many will be glad to see his place filled by a gentleman of broader views and more polished manners. But possibly the doctor's late disagreeableness was due to his mental affection, and his misfortune should call forth our most charitable sympathies.

Suicides are becoming more frequent in our medical ranks, three having occurred in this State during the past month. An unusual one comes from the West. A recent convert to the faith-cure in Missouri believed himself possessed of the power to cure disease by laying on of hands. After trying in vain to cure his aunt's sore eyes, he concluded himself a failure and cut his own throat. How can we persuade our Eastern quacks to imitate the Missourian?

The colleges have opened here with long

matriculation-lists. The University of New York has probably outstripped the other schools, some say on account of easy examinations, but, as an outsider, it would seem to me to be from improved accommodations and the increasing prominence and personal popularity of Dr. A. H. Loomis.

COLLEGE OF PHYSICIANS AND SURGEONS.

This is the Medical Department of Columbia College, located in the city of New York.

FACULTY.

ALONZO CLARK, M.D., LL.D. (President), Pathology and Practical Medicine (Emeritus).
WILLARD PARKER, M.D., LL.D., Principles and Practice of Surgery (Emeritus).
JOHN G. CURTIS, M.D. (Secretary), Physiology and Hygiene.
THOMAS MASTERS MARKOE, M.D., Principles of Surgery.
WILLIAM DETMOLD, M.D., Clinical and Military Surgery (Emeritus).
THEODORE GAILLARD THOMAS, M.D., Clinical Gynecology.
JOHN THOMAS METCALFE, M.D., Clinical Medicine (Emeritus).
HENRY BERTON SANDS, M.D., Practice of Surgery.
JAMES WOODS McLANE, M.D., Obstetrics, Gynecology, and Diseases of Children.
THOMAS TAUNTON SABINE, M.D., Anatomy.
CHARLES FREDERIC CHANDLER, Ph.D., Chemistry and Medical Jurisprudence.
EDWARD CURTIS, M.D., Materia Medica and Therapeutics.
FRANCIS DELAFIELD, M.D., Pathology and Practical Medicine.
WILLIAM HENRY DRAFER, M.D., Clinical Medicine.

CLINICAL PROFESSORS.

CORNELIUS REA AGNEW, M.D., Diseases of the Eye and Ear.
ABRAHAM JACOBI, M.D., Diseases of Children.
FESSENDEN NOTT OTIS, M.D., Venereal Diseases.
EDWARD CONSTANT SEGUIN, M.D., Diseases of the Mind and Nervous System.
GEORGE MOREWOOD LEEFERTS, M.D., Laryngoscopy and Diseases of the Throat.
WILLIAM TILLINGHAST BULL, M.D., Demonstrator of Anatomy.
GEORGE HENRY FOX, M.D., Diseases of the Skin.
THEOPHILE MITCHELL PRUDDEN, M.D., Director of the Physiological and Pathological Laboratory of the Alumni Association.
ROBERT FULTON WEIR, M.D., Surgery.
WILLIAM STEWART HALSTED, M.D., First Assistant Demonstrator of Anatomy.
FRANCIS HARTMAN MARKOE, M.D., Second Assistant Demonstrator of Anatomy.
GEORGE MONTGOMERY TUTTLE, M.D., Assistant to the Chair of Obstetrics.

The yearly course consists of but one session, of seven months' duration. The seventy-sixth course begins on Monday, October 1, 1883, and lasts until about the 1st of May, 1884.

Teaching by recitation forms a prominent feature of the course, the classes being conducted daily.

The fee for the course is \$40; for any single branch, \$7. A full course counts as time spent with a preceptor.

The fees for the session are the same as at the other large colleges. The dissecting-room is open during the whole course.

Requirements for Graduation.—In the usual statement requiring two full courses, it is specified that the two must not have begun during the same calendar year. Three courses are recommended,—the first including physics

and chemistry, anatomy, and physiology; the second, all the branches taught; the third, materia medica and therapeutics, pathology and practical medicine, surgery, obstetrics, and gynecology. The Faculty state that a majority of the students of the college follow this plan. A regular course in dissection is obligatory. Certificates of preceptorship are not accepted from homœopathic, eclectic, or other "irregular" practitioners, even if they are graduates of regular medical schools.

The examinations are in writing, the personality of the candidate not being known when the decision is given upon his papers.

BELLEVUE HOSPITAL MEDICAL COLLEGE.

During the year the Faculty of this college have met with a serious loss in the death of Prof. Van Buren, who held the chair of surgery. In the spring Dr. Joseph W. Howe resigned his position as clinical professor of surgery. With these exceptions, there have been no noteworthy changes in the teaching corps, which is now constituted as follows:

FACULTY.

ISAAC E. TAYLOR, M.D. (President), Obstetrics and Diseases of Women and Children (Emeritus).
FORDYCE BARKER, M.D., LL.D., Clinical Midwifery and Diseases of Women.
BENJAMIN W. MCCREADY, M.D., Materia Medica and Therapeutics (Emeritus).
AUSTIN FLINT, M.D., LL.D., Principles and Practice of Medicine and Clinical Medicine.
FREDERIC S. DENNIS, M.D., Principles and Practice of Surgery and Clinical Surgery.
LEWIS A. SAYRE, M.D., Orthopædic Surgery and Clinical Surgery.
ALEXANDER B. MOTT, M.D., Clinical and Operative Surgery.
WILLIAM T. LUSK, M.D., Obstetrics and Diseases of Women and Children and Clinical Midwifery.
A. A. SMITH, M.D., Materia Medica and Therapeutics and Clinical Medicine.
AUSTIN FLINT, JR., M.D. (Secretary), Physiology and Physiological Anatomy.
JOSEPH D. BRYANT, M.D., Anatomy and Clinical Surgery and (Associate) Orthopædic Surgery.
R. OGDEN DOREMUS, M.D., LL.D., Chemistry and Toxicology.
EDWARD G. JANEWAY, M.D., Diseases of the Nervous System and Clinical Medicine and (Associate) Principles and Practice of Medicine.

PROFESSORS OF SPECIAL DEPARTMENTS.

HENRY D. NOYES, M.D., Ophthalmology and Otology.
EDWARD L. KEYES, M.D., Cutaneous and Genito-Urinary Diseases.
JOHN P. GRAY, M.D., LL.D., Psychological Medicine and Medical Jurisprudence.
WILLIAM H. WELCH, M.D., Pathological Anatomy and General Pathology, and Demonstrator of Anatomy.
J. LEWIS SMITH, M.D., Clinical Professor of Diseases of Children.
CHARLES A. DOREMUS, M.D., Ph.D., Professor Adjunct to the Chair of Chemistry and Toxicology.
BEVERLEY ROBINSON, M.D., Clinical Professor of Medicine.
FRANCKE H. BOSWORTH, M.D., Diseases of the Throat.

FACULTY FOR THE SPRING SESSION.

FREDERICK A. CASTLE, M.D., Pharmacology.
WILLIAM H. WELCH, M.D., Pathological Histology.
T. HERRING BURCHARD, M.D., Surgical Emergencies.
CHARLES S. BULL, M.D., Ophthalmology and Otology.
LEROY MILTON YALE, M.D., Diseases of the Joints.

The twenty-third regular session began on Wednesday, September 19, 1883, and will extend to the latter part of March, 1884. At its

close, the spring session begins, and lasts until about the middle of June.

Weekly examinations are held by the Faculty. These examinations are for the graduating class only, but all the students are allowed to be present. The examinations are free. In addition, special practical instruction is given to candidates for graduation by practical exercises in medicine, surgery, gynecology, ophthalmology, and otology. These exercises are designed especially for third-course students who have passed their final examinations in the elementary branches. They are extended, however, to all candidates for graduation, so far as practicable without preventing them from attending the didactic lectures.

The usual fees for the winter session are required.

For graduation, candidates must be twenty-one years of age; must have studied three years, after the age of eighteen, with a regular physician or regular physicians in good standing, inclusive of the time spent in attending medical lectures; must have attended two full courses of lectures, the last being in this college; must present certificates of at least one course of dissections at this or some other accredited college empowered to confer the degree of M.D.; must have proper testimonials of character, and must pass a satisfactory examination in each of the seven departments of instruction. Two full courses of lectures are absolutely required, and no period of practice is taken as an equivalent for one course.

Spring Session of Recitations and Lectures.

—The recitations are under the direction of Dr. H. Goldthwaite and Professors Dennis, Welch, and C. A. Doremus. The ticket to the recitations and lectures is \$40.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

Since the opening of the last annual session, Prof. J. W. S. Arnold has retired from the actual duties of the chair of physiology and histology, but retains a connection with the Faculty as professor emeritus of those branches. Professor Stimson succeeds Professor Arnold, and Dr. S. O. Van der Poel has been added to the Faculty as professor of public hygiene. A considerable addition has been made to the building, rendering it now, the Faculty state, the largest of its kind in the country. A dispensary has been added.

FACULTY.

ALFRED C. POST, M.D., LL.D. (President), Clinical Surgery (Emeritus).
CHARLES INSLEE PARDEE, M.D. (Dean) Otology.
J. W. S. ARNOLD, M.D., Physiology and Histology (Emeritus).
JOHN C. DRAPER, M.D., LL.D., Chemistry.
ALFRED L. LOOMIS, M.D., Pathology and Practice of Medicine.
WILLIAM DARLING, M.D., LL.D., F.R.C.S., General and Descriptive Anatomy.

WILLIAM H. THOMSON, M.D., Materia Medica and Therapeutics, and Diseases of the Nervous System.
J. WILLISTON WRIGHT, M.D., Surgery.
WILLIAM M. POLK, M.D., Obstetrics and Diseases of Women and Children.
S. OAKLEY VAN DER POEL, M.D., LL.D., Public Hygiene.
LEWIS A. STIMSON, M.D., Physiology and Histology, Clinical Lecturer on Surgery.
STEPHEN SMITH, M.D., Clinical Surgery.
A. E. MACDONALD, LL.B., M.D., Medical Jurisprudence and Diseases of the Mind.
HERMAN KNAPP, M.D., Ophthalmology.
FANEUIL D. WEISSE, M.D., Practical and Surgical Anatomy.
R. A. WITTHAUS, M.D., Physiological Chemistry.
AMBROSE L. RANNEY, M.D., Curator of Museum.
JOSEPH E. WINTERS, M.D., Demonstrator of Anatomy.

ADJUNCT LECTURERS.

F. R. S. DRAKE, M.D., Practice of Medicine.
N. M. SHAFFER, M.D., Orthopaedic Surgery.
JOSEPH E. WINTERS, M.D., Diseases of Children.
WILLIAM C. JARVIS, M.D., Laryngology.
LAURENCE JOHNSON, M.D., Medical Botany.
P. A. MORROW, M.D., Dermatology.

The preliminary term begins on Wednesday, September 19, 1883, and extends to the beginning of the regular winter course, October 3. The spring session begins at the close of the winter course, in the middle of March, 1884, and continues for ten weeks. Only the winter course is obligatory.

Bedside and Laboratory Instruction.—The graduating class is divided into sections of about twenty-five each, which receive separate instruction for one or two hours daily throughout the term.

The fees for the winter session are the same as at the Bellevue Hospital Medical College.

The requirements for graduation are practically the same as at the other large colleges.

LONG ISLAND COLLEGE HOSPITAL, BROOKLYN, NEW YORK.

The Faculty express the belief that they have succeeded better in practically uniting a medical school with a hospital than any other institution in this country, since all the instruction is given in the hospital building.

FACULTY.

SAMUEL G. ARMOR, M.D., LL.D. (Dean), Principles and Practice of Medicine and Clinical Medicine.
GEORGE W. PLYMPTON, M.D., Physics, Chemistry, and Toxicology.
CORDYON L. FORD, M.D., LL.D., Anatomy.
ALEXANDER J. C. SKENE, M.D., Diseases of Women.
JARVIS S. WIGHT, M.D. (Registrar), Operative and Clinical Surgery.
JOSEPH H. RAYMOND, M.D., Physiology and Sanitary Science.
EDWARD SEAMAN BUNKER, M.D., Histology and General Pathology.
JOHN D. RUSHMORE, M.D., Surgery.
JOHN A. MCCORKLE, M.D., Materia Medica, Therapeutics, and Clinical Medicine.
CHARLES JEWETT, M.D., Obstetrics and Diseases of Children.

The collegiate year is divided into two terms, the preliminary and the regular term. The elementary branches are taught in the former mainly by recitations, the students being divided into three grades. At present the graded course is optional. This preliminary term began September 19, 1883, and the regular term begins January 2, 1884. The annual Commencement takes place May 21, 1884.

Requirements for Graduation.—In addition to the usual requirements, practical anatomy to the extent of having dissected every region of the body, and laboratory courses in chemistry, histology, and pathology. The examination is both oral and in writing. No thesis is required.

Fees.—Yearly matriculation, \$5; preliminary term, \$40; regular term, \$100; demonstrator's ticket, \$5; graduation, \$25; practical chemistry, \$5.

WOMAN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY.

FACULTY AND INSTRUCTORS.

ELIZABETH BLACKWELL, M.D., Hygiene (Emeritus).
JAMES R. LEAMING, M.D., Principles and Practice of Medicine (Emeritus).
EMILY BLACKWELL, M.D., Obstetrics and Gynecology.
GERARDUS H. WYNKOOP, M.D., Surgery.
MARY PUTNAM JACOBI, M.D., Materia Medica and Therapeutics.
EDWARD H. JANES, M.D., Hygiene.
MARY WATTLES FAUNCE, M.D., Anatomy.
A. R. ROBINSON, M.D., Histology.
C. L. DANA, M.D., Physiology.
HENRY N. HEINEMAN, M.D., Principles and Practice of Medicine.
T. M. CHEESEMAN, JR., M.D., Demonstrator.
S. M. ROBERTS, M.D. (Clinical), Diseases of Children.
D. M. STIMSON, M.D. (Clinical), Surgery.
E. B. BRONSON, M.D. (Clinical), Diseases of the Skin.
A. B. JUDSON, M.D., Lecturer on Orthopædic Surgery.
ELIZABETH M. CUSHIER, M.D., Lecturer Adjunct on Obstetrics.
R. W. AMIDON, M.D., Lecturer Adjunct on Therapeutics.
W. R. BIRDSELL, M.D., Lecturer on Nervous Diseases.
JOSEPHINE CHEVALIER, Lecturer on Chemistry, and Laboratory Instructor.
SARAH J. MCNUTT, M.D., Instructor in Surgery.
MARY T. BISSELL, M.D., Instructor in Physiology.
JOSEPHINE WALTER, M.D., Instructor in Practice.
GRACE PECKHAM, M.D., Instructor in Obstetrics.

The college year consists of a session of eight months, beginning on the 1st of October and ending with the last day in May.

A preliminary examination is required of applicants who do not show a certificate from a literary institution. Students must attend three entire sessions, graded as follows: *first year*, anatomy, chemistry, physiology, materia medica, and practical work in the anatomical rooms and chemical laboratory; *second year*, the same, also histology, obstetrics, surgery, practice, therapeutics, and hygiene; *third year*, the latter departments continued, and practical medical work under the direction of the teachers, with clinical reports of cases attended. Students desiring to take a four-years course will confer with the secretary on matriculating, and be instructed how to proceed.

Requirements for Graduation.—Three winter sessions of lectures, with clinical instruction according to the course laid down; satisfactory examinations before the Faculty and Board of Examiners.

Fees.—Matriculation, \$5; demonstrator's ticket, \$10; professors' tickets, each \$15,—\$105; graduation, \$30.

NEW YORK POLYCLINIC.

The second year of the New York Polyclinic finds it in a flourishing condition. It is

like the preceding school in its essential features, except that didactic lectures form no part of the plan of instruction, as the school was organized with the special view of teaching only clinical medicine and surgery to physicians. The numbers in the various classes are limited, so that each can have an opportunity for personal investigation of patients. The Polyclinic is open all the year, each special course extending over six weeks. The fees are about the same as those of the Post-Graduate Medical School. The Faculty is as follows:

FACULTY.

JAMES R. LEAMING, M.D., Professor of Diseases of the Chest, President of the Faculty.
E. DARWIN HUDSON, JR., M.D., Professor of General Medicine.
JOHN H. RIPLEY, M.D., Professor of Diseases of Children.
LOUIS ELSBERG, M.D., Professor of Laryngology and Rhinology.
LONDON CARTER GRAY, M.D., Professor of Diseases of the Mind and Nervous System, and Electro-Therapy.
RICHARD C. BRANDIS, M.D., Professor of Laryngology, Rhinology, and Otology.
ANDREW R. ROBINSON, M.D., Professor of Dermatology.
EDWARD B. BRONSON, M.D., Professor of Dermatology.
JOHN A. WYETH, M.D., Professor of General and Genito-Urinary Surgery.
A. G. GERSTER, M.D., Professor of General and Genito-Urinary Surgery.
PAUL F. MUNDÉ, M.D., Professor of Gynecology.
W. GILL WYLIE, M.D., Professor of Gynecology.
JAMES B. HUNTER, M.D., Professor of Gynecology.
EMIL GRUENING, M.D., Professor of Ophthalmology.
DAVID WEBSTER, M.D., Professor of Ophthalmology.
V. P. GIBNEY, M.D., Professor of Orthopædic Surgery.
WALTER R. GILLETTE, M.D., Professor of Obstetrics.
GEORGE B. FOWLER, M.D., Instructor in Physiological Chemistry.

THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

This was the first institution of its kind in New York City, and was organized in June, 1882, the plan of instruction being based upon the post-graduate methods which have been successfully employed for many years in the medical centres of Europe. Clinical instruction constitutes a fundamental feature of the school. Systematic or didactic teaching holds a subordinate position. No under-graduates are admitted.

The curriculum embraces a regular and an intermediate term. The regular term began October 1, 1883, and will continue until June 2, 1884. The other term is intermediate, and will continue until October 6, 1884. Each course continues seven weeks, and a single one or any number may be taken. The fees for individual courses run from ten to twenty-five dollars each. No matriculation fee is required, and no degrees are conferred.

The Faculty is as follows:

FACULTY.

JAMES L. LITTLE, M.D., Professor of Clinical and Operative Surgery.
WILLIAM A. HAMMOND, M.D., Professor of the Diseases of the Mind and Nervous System, and of Medical Electricity.
D. B. ST. JOHN ROOSA, M.D., LL.D., Professor of the Diseases of the Eye and Ear.
FREDERIC R. STURGIS, M.D., Professor of the Diseases of the Skin and Genito-Urinary Organs, and of Venereal Diseases.

CLINTON WAGNER, M.D., Professor of the Diseases of the Nose and Throat.
 THOMAS E. SATTERTHWAITE, M.D., Professor of Pathology and General Medicine.
 MARY PUTNAM JACOB, M.D., Professor of the Diseases of Children.
 BENJAMIN F. DAWSON, M.D., Professor of the Diseases of Women.
 EDWARD C. SPITZKA, M.D., Professor of the Anatomy and Physiology of the Nervous System.
 M. JOSIAH ROBERTS, M.D., Professor of Orthopædic Surgery and Mechanical Therapeutics.
 EDWARD L. PARTRIDGE, M.D., Professor of Obstetrics.
 CHARLES L. DANA, M.D., Professor of the Diseases of the Mind and Nervous System, and of Medical Electricity.
 ALEXANDER J. C. SKENE, M.D., Professor of the Diseases of Women.
 ANDREW H. SMITH, M.D., Professor of Clinical Medicine and Therapeutics.

Our correspondent states further, concerning medical education in New York, that, in addition to the information to be obtained from the regular announcement of the medical colleges just given, it may safely be said that there exists a general sentiment in the profession that a license to practise should be required, and the standard of graduation certainly be elevated. This object can be obtained only by adopting one or more of three methods,—viz., first, by establishing a preliminary examination, to pass which will require on the part of the prospective medical student an evidence of a certain degree of mental training and of general education; second, by lengthening the term of the medical course, and adding to the requirements for graduation; third, by additional facilities for learning and improved methods of instruction.

While the medical colleges, as well as the profession in general, seem to appreciate the need for higher medical education, any means that may be suggested for attaining to this will necessarily meet with greater or less opposition. A college which draws most of its students from the larger cities, where a collegiate education is more usual, would be more likely to favor a strict preliminary examination, and demand a higher degree of proficiency in general education, than one which receives the majority of its recruits from the West and South and rural districts, where the standard of general education is lower. The matter of extending the time of study and attendance upon lectures seems to meet with general approval, but the college which takes the first step in this direction will probably do so at the expense of a diminished number of students at its halls, as was proved not long ago by the Bellevue Hospital Medical College, which, for this reason, has returned to its former requirements of only two years' attendance and one under a preceptor. Should all the medical colleges throughout the country determine upon a three years' course simultaneously, doubtless the New York colleges would heartily join in the move. Later a four years' course might possibly be adopted. It would probably prove some time before the step would be taken, based upon a demand therefor on the part of the majority of those

just entering upon their medical studies. Some years will probably pass by before a call for a preliminary collegiate education, especially instruction in the dead languages, as a requisite in entering upon the study of medicine, will meet with much favor, at least with a sufficient amount of favor to lead to its general adoption. The learning to be acquired at a well-regulated and well-founded medical college is so varied and so practical that even a large number of the general profession, as well as the college professors, seem to think that it sufficiently replaces any want not met by our excellent public schools. The colleges here certainly have all the main essentials for giving their students an excellent theoretical and practical medical education, and their greatest deficiency at present is an inability to make a three or four years' course compulsory. The opportunities for clinical, post-mortem, dissection, pathological, histological, and general laboratory instruction are very good. One feature introduced into the University last year seems to be propitiatory of excellent results,—viz., the dividing of the graduating class into sections, and giving separate instruction at the bedside in the hospital for one or two hours daily. Laboratory instruction is also made a special feature at this college. The classes at the three colleges have opened with about their usual fullness. From the Catalogue for 1883, the number of students at the College of Physicians and Surgeons was 543; the number of graduates, 125. Number in attendance at the University, 528; graduates, 163. Number in attendance at Bellevue, 467; graduates, 167. Of course, the percentage of rejections at the examination for the title of "M.D." cannot be exactly estimated from these figures, but it would seem that the requirements were not of a uniform standard, or else that the training was not equally perfect.

A graded course is optional, and usually is recommended, but it will not at all be likely to be made obligatory until the term shall have been lengthened. It seems to be regarded as of much less importance than the lengthening of the term.

The general sentiment of the medical profession in this city, and, so far as can be judged, throughout the State, is doubtless in favor of placing the power of granting a license to practise in the State in the hands of a State board of examiners; but as to the practicability of it, probably the most ardent supporters of such a project would admit that there is some doubt. The difficulty of keeping out politics, of maintaining harmony among the exclusive sects, etc., all constitute difficulties in the way of such a movement. The medical colleges would, no doubt, consider themselves fully as able to judge of their students' proficiency as any medical examining board, however constituted.

Whatever may be considered the best

means of bringing it about, whether by one sort of medical politics or another, whether by one code of ethics or another, or by no code, the times certainly point to a desire for a higher standard of medical education in the city and and State of New York.

MEDICAL EDUCATION IN BALTIMORE.

IN the matter of medical education, Baltimore has made great progress during the past decade, not only in the number of colleges which have been organized and in the number of students attending the lectures given in them, but also in the higher standard of requirements insisted upon as qualifications for graduation. Several factors are concerned in the production of this desirable condition of things. In the first place, the general sentiment in favor of a more thorough education has had its effect; secondly, the honorable rivalry between the two leading schools has had a reciprocal effect in stimulating each to do its best in the endeavor to gain the lead over the other; and, finally, perhaps the largest share of this good effect is to be attributed to the influence of the Johns Hopkins University, our young but already renowned institution of learning.

JOHNS HOPKINS UNIVERSITY.

As the Johns Hopkins University promises to occupy a large share in the movement towards attaining the *highest* standard of medical as well as other education in this country, it will be appropriate to give an account of what is proposed to be done by this institution in furtherance of this object.

Seven years ago, Dr. John S. Billings, of the United States Army, delivered a course of lectures on the "History of Medicine" before the University, at the close of which he gave an outline of the requirements which probably would be demanded of those who sought the degree of M.D. in her halls. Three years ago, the first beginning was made towards the realization of the plan sketched by Dr. Billings, in the establishment of a special course preparatory to the professional study of medicine. This course comprises three years' study in certain branches of knowledge which most medical schools in this country seem to consider as non-existent, or, at least, of little benefit to the medical student. The candidate for this preparatory course is required to pass a preliminary examination in arithmetic, algebra to simple equations, involving not more than two unknown quantities, geometry, first three books of Euclid, or equivalent, plane trigonometry, and the use of logarithms. He will also be examined in easy Latin (Cæsar and Virgil) and the elements of Latin grammar. A knowledge of the mother tongue, so much neglected generally, will also be required, and a satisfactory test in spell-

ing, punctuation, and syntax must be passed. French, German, and drawing are also desirable, but not necessary at the preliminary. An exact, if not very extensive, knowledge of physical geography will be required of all candidates. After entrance the student will receive instruction in physics, chemistry, biology, English, German, and French, physical geography, history, logic, ethics, and psychology, with laboratory exercises in the first three subjects mentioned. The course on biology includes morphology, histology, physiology, human and comparative anatomy, and marine laboratory work. At the end of this course (three years), the student, if successful in his examinations, receives the degree of B.A. and is considered fitted to begin the study of medicine proper. This, according to Dr. Billings's schedule (whether this will be modified or not I am not aware), is to occupy a further four years, in the study of professional subjects proper, three of which are to be spent in practical work in the hospital, the doctor's laboratory. After these seven years' study, and several examinations in the mean while, the candidate may finally hope to append M.D. (Balt.) after his name, if his examinations in the various subjects prove satisfactory.

The fees for the course preparatory to the study of medicine are eighty dollars per year, to be paid in two instalments,—October and February. Twenty dollars must, in addition, be paid in the chemical and biological laboratories, for material and the use of apparatus.

The question may justly be asked, "Will many avail themselves of such opportunities?" As regular candidates for a degree, I fear not. Even Dr. Billings thought that the Johns Hopkins Medical School, in spite of its munificent endowment, would probably never graduate a class of more than twenty-five at a time. At present even this seems a sanguine view to take of it, for only very few students are taking the medical preparatory course in its entirety.

No account of the medical advantages of the Johns Hopkins School would be complete, however, without a reference to the magnificent hospital which is now in progress of building. As is probably known to all the readers of these pages, the late Mr. Hopkins, in making provision for the university which was to bear his name, directed that three and a half million dollars should be appropriated out of his estate for the construction of a charity hospital. The trustees have determined that in the essential requisites of a hospital this should be a model institution, and, as far as I am able to judge, this object will be attained. One of the common wards is now nearly completed, and an examination of it creates a strong desire to see the whole establishment finished at an early day. It will probably still be several years before the hospital is open for the reception of pa-

tients, though it is possible the year after next may see the opening of part of it.

Professor H. Newell Martin, the University professor of biology, has been appointed professor of physiology in the medical school, and Professor Ira Remsen, who occupies the chair of chemistry in the University, will teach the same branch to the medical students. Dr. Billings was tendered the chair of hygiene, but was compelled to decline on account of his absorbing duties in connection with the National Medical Library. It is said, however, that he will deliver a course of lectures on public hygiene before the University during the coming winter.

The indications seem to be that the diploma of M.D. from the Johns Hopkins University will indicate an amount of thorough professional knowledge approached by no similar institution in this country, and exceeded by none anywhere.

I am reminded, however, that however rapidly this good time may be coming, it has not yet arrived. The average medical student is still wanting in many of the graces of a polite education, and in not a few of the accomplishments actually requisite to study his text-books or listen to his lecturers with the greatest amount of profit. This brings me back to those institutions which are in our midst for the instruction of students in medicine alone, and which do not aim at the high standard of the Johns Hopkins, but modestly desire to turn out doctors who are able to diagnose a case of typhoid fever from one of pneumonia (and I'm sure this isn't always the easiest thing to do), and who know how to treat the case when the diagnosis is made.

UNIVERSITY OF MARYLAND.

Our oldest established medical school is the University of Maryland, which is now in its seventy-seventh session. Most of the physicians in this city are graduates of the University, and regard their old alma mater with much affection. Sometimes it has seemed to me that this worship was carried to excess, for many of the alumni are such bitter partisans that they are unable or unwilling to admit that any one can be a safe, reliable, or honest practitioner unless his credentials are derived from the *Academia Terra Mariae*. During the last few years the Faculty has been rejuvenated by the infusion of a quantity of healthy young blood, and it is now in pretty good condition, with the weak points carefully guarded by an energetic reserve, which will preserve it against dangers hereafter. In 1881 the University obtained power from the Legislature to add departments of dentistry and pharmacy. The dental department was established last year, its principal strength being derived from the old Baltimore College of Dental Surgery, whose Dean seceded to the University and assumed charge of the dental department of that school.

The clinical instruction at the University is good, the lecturers being progressive men and excellent teachers. The Faculty has control of a large general hospital and outdoor service, from which the clinical material is drawn.

The Faculty is composed of Professors George W. Miltenberger, Obstetrics; Richard M. Sherry, Principles and Practice of Medicine; Samuel C. Chew, *Materia Medica*, Therapeutics, and Throat and Chest Diseases; Frank Donaldson, Clinics on Throat and Chest; Wm. T. Howard, Diseases of Women and Children, and Clinical Medicine; J. J. Chisolm, Eye and Ear; Francis T. Miles, Physiology and Diseases of Nervous System; L. McLane Tiffany, Surgery; J. E. Michael, Anatomy and Clinical Surgery; I. E. Atkinson, Pathology and Clinical Dermatology; F. J. S. Gorgas, Principles of Dentistry, Dental Surgery, and Mechanism; J. H. Harris, Operative and Clinical Dentistry; Randolph Winslow, Demonstrator of Anatomy. Prof. Aiken, for about two generations Professor of Chemistry, has resigned, and his place has been temporarily filled by the appointment of Dr. R. Dorsey Coale, a graduate and associate of the Johns Hopkins University, as Lecturer on Chemistry. Prof. Tiffany is Dean of the medical and Prof. Gorgas of the dental department. The department of pharmacy has not yet been organized.

The requirements for graduation are—three years of study, two full courses of lectures, (three recommended), twenty-one years of age, a thesis or clinical report of cases. Fees—\$120 for the lecture tickets, \$5 for matriculation, \$10 for demonstrator's ticket. For beneficiary students the ticket to all the lectures is \$50. The graduation fee is \$30.

THE COLLEGE OF PHYSICIANS AND SURGEONS.

The College of Physicians and Surgeons, an offspring and successor to the Washington University, was organized in 1872, and is now the most prosperous school in the city. The elements of weakness that at first existed in the Faculty have been gradually weeded out, new facilities have been added, and few schools are better qualified to give thoroughly practical instruction to their students. The Faculty owns a large general hospital, a lying-in asylum endowed by the State, a woman's hospital near the college and rendering its material available for public clinics, and a large dispensary service. Physiological and chemical laboratories have been established, and, beginning with the present session, practical work in the laboratories will be an essential prerequisite to graduation. The school is fortunate in having for its Dean one of the most energetic and clever businessmen in the profession here, and it is largely owing to his untiring industry and tact that the school has attained to its present success. The Faculty is composed for the most part of

active, earnest, and thorough teachers. Their names are—Professors Thomas Opie, Obstetrics and Puerperal Diseases; John S. Lynch, Principles and Practice of Medicine, and Throat and Chest Diseases; T. S. Latimer, Physiology and Diseases of Children; A. F. Erich, Diseases of Women; A. Friedenwald, Eye and Ear; C. F. Bevan, Anatomy, Genito-Urinary and Orthopædic Surgery; Oscar J. Coskery, Surgery; A. B. Arnold, Clinical Medicine and Diseases of Nervous System; Richard Gundry, *Materia Medica*, Therapeutics, and Mental Diseases; William Simon, Chemistry; George H. Rohé, Hygiene and Clinical Dermatology. The demonstrators are Drs. J. W. Chambers and J. H. Branham, of Anatomy, and W. D. Booker and H. J. Berkeley, of Physiology. Prof. Opie is the Dean.

The requirements for graduation are—three years' medical study, two full courses of lectures (three recommended), dissection during both terms, practical work in chemical and physiological laboratories. No thesis is demanded. The tickets of those schools holding their regular session in summer are not accepted at this school as equivalent to attendance on a full course of lectures. The full fees for the course are \$120. Privileged students—*i.e.*, beneficiaries—are admitted on payment of \$55. The graduation fee is \$30.

WOMAN'S MEDICAL COLLEGE.

Last year a number of progressive young men, recognizing the importance of offering to women an opportunity to study medicine, and place the gentle sex here on an equal footing with their sisters in Philadelphia, New York, and Chicago, organized the Woman's Medical College of Baltimore. The success of the college has exceeded the anticipations of the organizers, and demonstrated the correctness of their belief that the movement started by them met an unquestionable demand. A hospital and dispensary are connected with the college, and the institution is honorably striving for the success it deserves. The Faculty is fairly well qualified for its work, and consists of Professors John S. Lynch, Principles and Practice of Medicine; B. B. Browne, Diseases of Women; T. A. Ashby, Obstetrics; Randolph Winslow, Surgery; E. F. Cordell, *Materia Medica* and Therapeutics; W. D. Booker, Physiology and Diseases of Children; R. H. Thomas, Throat and Chest Diseases; John G. Jay, Anatomy and Operative Surgery; Cameron Piggot, Lecturer on Chemistry; and Thomas P. McCormick, Demonstrator of Anatomy. Professor Booker is Dean.

The requirements are—a preliminary examination in the ordinary branches of an English common-school education, attendance on two full courses of lectures (three recommended), and on clinics and dissections. Fees, \$75 for full course of lectures. Matriculation, \$5. Dissection, \$10. Graduation, \$30.

BALTIMORE MEDICAL COLLEGE.

No notice of medical education in Baltimore would be complete without at least a passing reference to a peculiar aberration of the teaching instinct which resulted two years ago in the organization of what in its prospectus is termed the Baltimore Medical College, but which is generally spoken of by the profession as the "Christian College." The feature in the charter of this college which caused most comment was the provision that all the professors in the institution should likewise be professors of Christianity. At the introductory exercises of the present year the President is reported to have said that the "establishment of a pulpit is in contemplation,"—whatever that may mean. During the first two sessions the lectures were delivered to a class of men, women, and preachers. At present the women are excluded from the benefits of the teaching, and the vague reference to the pulpit, above mentioned, seems to indicate that the preachers will enjoy a monopoly of the instruction at an early day. This school, we believe, has not succeeded in winning the confidence of the profession of this city, as the controlling elements in its administration are not such as to inspire us with confidence in its reliability. The State Board of Health of West Virginia refuses to recognize its diplomas, and the Illinois State Board will probably take similar action when it shall be called upon for a decision.

The climatic and social conditions of Baltimore render it an attractive place for students to pass their period of pupilage. Board and lodging can be obtained at from three to six dollars per week. At the latter figure the accommodations are quite good,—better, in my experience, than in any other large city in the country.

Allow me to add a single suggestion. Baltimore is a bad place to begin practice. According to the census, there are more physicians to population in Maryland than in any other State in the Union.

MEDICAL EDUCATION IN BOSTON.

HARVARD UNIVERSITY, MEDICAL DEPARTMENT.

THE advance of medical education in America, and the opportunities for acquiring a thorough training for after-practice, are nowhere better illustrated than at the medical school of Harvard University. Each year, for the past decade, has seen some improvement. Acting upon the idea that preliminary training is necessary, the entrance-examination was instituted, which at first caused a diminution of students, only to result in increasing their number and quality year by year. The school this session begins its hundred-and-first year, with lectures in its

new building, erected entirely by the contributions of its friends, at a cost of three hundred thousand dollars. The building is centrally situated, in that section of Boston destined to remain the educational centre for years to come, having for its neighbors the Massachusetts Institute of Technology, the Museums of Fine Arts and Natural History, while close adjoining is the land recently given the city by the State for the purpose of a public library.

The building is central in respect to its clinical departments, being equidistant from the Massachusetts General, City, Children's, Free Women's Hospitals, and Boston Dispensary.

The students can find rooms, at moderate price, within easy walking-distance of the school.

The building itself is of plain brick, with sandstone trimmings, occupying one hundred and twenty-two feet on Boylston Street, ninety on Exeter Street. Its interior arrangements will be a source of great interest to medical men. Its facilities for thorough, careful observation in laboratory-work are unsurpassed in this country. As one enters the building, he is struck by the excellence of its architecture: it is that of a central hall, lighted from above, containing the stairway; about this rooms are arranged. On the left, as one enters, is the janitor's room, where letters and bundles for the students are received and arranged so that they will easily attract the attention. Continuing towards the rear of the building, one passes through an entry to a large, sunny room provided with desks and chairs, for the use of students as a reading-room; opening from this is a smoking-room, where conversation and smoking are allowed, thus, in its very foundation, providing for the comfort of the student. The remainder of the ground-floor is devoted to the library and room for the Faculty.

The second floor is devoted entirely to the physiological and chemical laboratories, and here provision has been made for students of advanced standing and those desiring an experimental knowledge of these subjects. Adjacent to the laboratories are the lecture-rooms for those subjects.

The third floor is given up to the lecture-rooms for anatomy and surgery. The seats are arranged on the plan of an amphitheatre, thus affording each person an unobstructed view. Here also is the Warren Museum, containing over seven thousand valuable specimens, to which the student has access, and on the west side two large, general lecture-rooms, where those topics not requiring demonstration are to be given.

On the fourth floor are the entrances to the amphitheatre for the student. Passing to the front of the building, one enters the pathological laboratory. Here provision is made for microscope-work, the room being well lighted from above and sides. In the

southeast corner of this floor is a small amphitheatre, to be used for operative courses on surgery and obstetrics, giving opportunities for special demonstration. In front of this, occupying the western side of the fourth floor, is the room for practical anatomy. This is well supplied with direct light by means of large sky-lights.

Having examined the building, what is necessary that one may use it as a student? The catalogue says,—

All candidates for admission, excepting those who have passed an examination for admission to Harvard College, must present a degree in Letters or Science from a recognized college or scientific school, or pass an examination, on the Monday preceding the last Wednesday in June or September, at 10 A.M., in the following subjects:

1. **ENGLISH.** Every candidate shall be required to write, legibly and correctly, an English composition of not less than two hundred words, and also to write English prose from dictation.

2. **LATIN.** The translation of easy Latin prose.

3. **PHYSICS.** A competent knowledge of Physics (such as may be obtained from Balfour Stewart's Elements of Physics).

4. **ELECTIVE SUBJECT.** Each candidate shall pass an approved examination in such one of the following branches as he may elect: French, German, the Elements of Algebra or of Plane Geometry, Botany.

Whenever the candidate shall give evidence of having passed a satisfactory examination in any of the above requirements either at Harvard College or at the Lawrence Scientific School, a subsequent examination in such subjects will not be demanded for his admission to the Medical School.

The examinations will be conducted in writing, and specimens of the papers used will be sent on application to the Secretary. In judging the work of the candidate, the spelling, grammar, and construction will be considered.

Graduates in medicine will not be required to pass this examination on joining the school.

No student becomes a member of the school until he has registered his name with the Secretary of the Faculty.

Having satisfied ourselves of our ability to enter, who are to be our instructors if we conclude to be instructed by them? The two senior members of the Faculty until recently, Drs. Ellis and O. W. Holmes, have passed from active medical teaching. The Faculty that now is, comprises the following members:

FACULTY.

CHARLES W. ELIOT, LL.D., President.

CALVIN ELLIS, M.D., Emeritus Professor of Clinical Medicine.

OLIVER W. HOLMES, M.D., LL.D., Emeritus Professor of Anatomy.

HENRY J. BIGELOW, M.D., Emeritus Professor of Surgery.

FRANCIS MINOT, M.D., Hersey Professor of the Theory and Practice of Physics.

JOHN P. REYNOLDS, M.D., Professor of Obstetrics.

HENRY W. WILLIAMS, M.D., Professor of Ophthalmology.

DAVID W. CHEEVER, M.D., Professor of Surgery.

JAMES C. WHITE, M.D., Professor of Dermatology.

ROBERT T. EDES, M.D., Professor of Materia Medica.

HENRY P. BOWDITCH, M.D., Professor of Physiology, Dean.

CHARLES F. FOLSOM, M.D., Assistant Professor of Mental Diseases.

FREDERICK I. KNIGHT, M.D., Assistant Professor of Laryngology.

CHARLES B. PORTER, M.D., Assistant Professor in Surgery.

J. COLLINS WARREN, M.D., Assistant Professor in Surgery.

REGINALD H. FITZ, M.D., Shattuck Professor of Pathological Anatomy.

WILLIAM L. RICHARDSON, M.D., Assistant Professor of Obstetrics.

THOMAS DWIGHT, M.D., Parkman Professor of Anatomy.

EDWARD S. WOOD, M.D., Professor of Chemistry.

WILLIAM H. BAKER, M.D., Assistant Professor of Gynecology.

WILLIAM B. HILLS, M.D., Instructor in Chemistry.

WILLIAM F. WHITNEY, M.D., Curator of the Anatomical Museum.

The course of instruction is arranged for three or four years, according as the student may elect, the Faculty strongly urging all those who can possibly do so to take the four-years course, having in view a prescribed course of four years. One who has been through a three-years course can readily see what an advantage it would be to be able to fill out in his fourth year those subjects which, from necessity, he was obliged to slight when the course was only three years. The amount of knowledge attempted in the third year is more than any student can digest: to persuade more students to remain four years is the present aim of the Faculty, and with this end in view a watchful care is kept that everything may be so provided as to induce to prolonged study and individual research, so that the fourth year shall be so attractive and evidently useful that students will desire to remain in the school from a conviction of advantages gained.

With this end in view, then, the course has been divided as follows:

FOUR-YEARS COURSE.

For the First Year.—Anatomy, Physiology, and General Chemistry.

For the Second Year.—Practical and Topographical Anatomy, Medical Chemistry, *Materia Medica*, Pathological Anatomy, Clinical Medicine, Surgery, and Clinical Surgery.

For the Third Year.—Therapeutics, Obstetrics, Theory and Practice of Medicine, Clinical Medicine, Surgery, and Clinical Surgery.

For the Fourth Year.—Ophthalmology, Otology, Dermatology, Syphilis, Laryngology, Mental Diseases, Diseases of the Nervous System, Diseases of Women, Diseases of Children, Obstetrics, Clinical and Operative Obstetrics, Clinical Medicine, Clinical and Operative Surgery, Forensic Medicine.

THREE-YEARS COURSE.

For the First Year.—Anatomy, Physiology, and General Chemistry.

For the Second Year.—Practical and Topographical Anatomy, Medical Chemistry, *Materia Medica*, Pathological Anatomy, Clinical Medicine, and Clinical Surgery.

For the Third Year.—Therapeutics, Obstetrics, Theory and Practice of Medicine, Clinical Medicine, Surgery, Clinical Surgery, Ophthalmology, Dermatology, Syphilis, Otology, Laryngology, Mental Diseases, Diseases of the Nervous System, Diseases of Women, Diseases of Children, Forensic Medicine.

HOSPITAL ADVANTAGES.

Besides these regular courses, special provision is made for the post-graduate course, in which the chances for clinical work are abundant.

The clinical advantages are such as are found only in large cities: to all the hospitals, both for clinical visits and to witness operations, the student has every opportunity.

At the Massachusetts General Hospital, nearly three thousand in its wards and twenty thousand in its out-patient department annually give excellent opportunity for that practical knowledge of disease which is so essential for the young physician. At the City Hospital, where four or five thousand are treated annually in its wards and twelve thousand in its out-patient department, ample opportunity is given for observing acute and contagious diseases: in the surgical wards,

recent injuries, fractures, and traumatic cases are of daily occurrence.

Operative surgery is to be seen at each hospital once a week, and, during a portion of the year, twice a week.

At the Massachusetts Charitable Eye and Ear Infirmary a large number of cases are treated each year, to all of which the student has access.

At the Boston Dispensary the number of patients is nearly twenty-seven thousand yearly, and here the student has an amount of auscultation and physical examination more than enough. All the physicians connected with the institution offer every courtesy to the student.

In the wards of this hospital, devoted exclusively to gynecological cases, the student has the opportunity of seeing the various forms of uterine disease.

At the Massachusetts Hospital, which has so many varied surgical operations, the City Hospital, with its acute cases and accidents, the out-patient departments of both hospitals, with their opportunities for physical examination, the Hospital for Women, giving to those sufficiently advanced access for the study of gynecology, the student has abundant illustration for his text-books.

CHICAGO.

ALMOST every Western town of any importance has its medical college. This city begins to count them by the dozen, and, if one may judge by the increasing numbers of young men in attendance each year, all appear to thrive. Indeed, medicine is now one of the easiest of the professions, and many hating hard work, mental or physical, purchase the right to a seat in the college lecture-room, and go through. With the closing days of last month our colleges renewed their activity: the attendance is larger than ever before, with the exception of one school, which shows a slight falling off. Each Faculty vies with the other in seeking favors, and promises increased facilities to patrons.

It is becoming fashionable in this city to advertise the operator and operations in surgery. Some invite the newspaper reporter to be present, others see to it that the paper is supplied with an entirely technical report of the case, and others go so far as to secure an announcement in advance, to be followed by an exhaustive description of the operation, in which the usual statements are made to the effect that the operation has been performed but twice before, and never till this time in this country. They usually close with the assurance that the operator and the patient are doing well.

Last week the popular mind was considerably agitated in this manner over the ligation of the common carotid.

The question of what shall be done with the city sewage is now pressing itself upon the attention of the authorities. That the present sewerage system is of a most imperfect and inadequate character is felt by all who have given the matter any serious consideration. The sewerage and the health of the city are so intimately connected that neglect of one is a sacrifice of the other. Our city does not profit by the experience of other cities; it does not begin where others left off, but begins where they began, and so gropes along, picking up a little sound knowledge at wide intervals and at great expense. The vast amount of filth flowing through the sewers into the lake, from whence we draw our water-supply, is with each year becoming a source of greater anxiety. There is a probability that we may adopt a slight modification of the system now in use in Paris, necessitating the purchase of about fifteen hundred acres of land not far from the city limits, or a system of intercepting sewers may be constructed by which the sewage would be passed rapidly through the canal and Illinois River to the Mississippi. In this connection it may be mentioned that the open grating placed over the man-holes to the sewers has in more than one instance been a direct source of disease to children and persons residing in the immediate vicinity. When the wind prevails from certain directions, the amount of gas escaping from those gratings is such as to compel residents near by to close windows and doors to shut out the stench. In some families it has produced nausea and vomiting and obscure and intractable disease.

On the evening of the 6th instant the Hahnemann Hospital was visited by fire, destroying the front portion, a building about forty by sixty-five feet. The excitement among the patients and officers ran high, but all escaped injury, and the fire was extinguished, saving the rear and principal part of the institution. The damage amounted to about ten thousand dollars, the building alone being insured. The loss will be considerable.

Dr. Jewell has resigned the professorship of nervous diseases in Chicago Medical College, and has been succeeded by Dr. Hay, late of Dubuque, Iowa.

CHICAGO, October 10, 1883.

CLEVELAND, OHIO.

[Our correspondent sends details about the colleges, which want of space prevents us from publishing. He gives his opinion of medical matters in this city as follows.—Ed. M. T.]

THERE are two regular medical colleges in Cleveland now in operation. The clinical advantages of each school are about the same, the Charity and City Hospitals being open to the students from each.

About two years ago, one of Cleveland's wealthy citizens proposed to the Faculty of each school that if they would unite and

form one, to be known as the "Western Reserve University Medical Department," he would give a considerable sum of money towards the erection of a fine college building. The offer was accepted, but in making up the Faculty Drs. Weber, Parker, Lowman, and Miller only were elected,—probably the ablest members of the Wooster school. The remaining ones felt so slighted at being left out in the cold, as it were, that they set about reorganizing a Faculty, being encouraged in such a step by the "University of Wooster," which institution claimed to have known nothing about their medical department consolidating with any other,—in fact, that the motto, "Non Anno sed Annis," inscribed over their portal, was just what they meant. As the matter stands, the Western Reserve medical department has the best Faculty and the largest number of students.

PROCEEDINGS OF SOCIETIES.

AMERICAN ACADEMY OF MEDICINE.

(Special report for the MEDICAL TIMES.)

THE Eighth Annual Meeting of the American Academy of Medicine was held in New York, at the New York Academy of Medicine, on Tuesday and Wednesday, October 9 and 10, 1883. The first session, on Tuesday afternoon, was called to order by the President, Dr. H. O. Marcy, of Boston, and prayer offered by Dr. Traill Green, of Easton. After the reading of the minutes of the meeting at Philadelphia last year, and the report of the Council, the Academy went into an election for Fellows. The following-named applicants, having been approved by the Council and by them recommended, were elected Fellows of the Academy: Dr. Z. B. Adams, Framingham, Mass.; Dr. E. B. Bronson, New York, N.Y.; Dr. A. Brown, Hellertown, Pa.; Dr. W. T. Clull, Schenectady, N.Y.; Dr. J. Corbin, Brooklyn, N.Y.; Dr. C. H. Crane, Surgeon-General, U.S.A., Washington, D.C.; Dr. F. L. Du Bois, Bridgeton, N.J.; Dr. E. L. Dunster, Ann Arbor, Mich.; Dr. J. Emerson, Detroit, Mich.; Dr. P. J. Farnsworth, Clinton, Iowa; Dr. F. H. Gerish, Portland, Me.; Dr. A. L. Gihon, Medical Director, U.S.N., Washington, D.C.; Dr. John Green, St. Louis, Mo.; Dr. E. Hartshorn, Philadelphia, Pa.; Dr. A. C. Kemper, Cincinnati, O.; Dr. R. P. Lincoln, New York, N.Y.; Dr. E. F. Mordough, Brooklyn, N.Y.; Dr. J. H. Patzki, U.S.A., St. Augustine, Fla.; Dr. Thomas J. Smith, Bridgeton, N.J.; Dr. J. A. Stewart, Baltimore, Md.; Dr. E. V. Stoddard, Rochester, N.Y.; Dr. J. K. Weaver, Norristown, Pa.; Dr. L. P. Walton, New York, N.Y.

Drs. T. Green, Steiner, and Birmingham were appointed as the nominating committee.

Dr. A. D. Rockwell, of New York, read a biographical sketch of his late associate, Dr. G. M. Beard, who, at the last meeting, was elected First Vice-President of the Academy. Dr. Rockwell entered more upon the inner life of his subject than his outward actions, trying to show what he *was* rather than what he did. Dr. Beard was a man of intense personality and self-reliance, amounting, in the minds of some, to excessive egotism. He was withal a courteous man, always ready to drop his work and listen to the conversation of others, whatever its worth. Perhaps the most striking characteristic was his humor, and out of this grew his reputation for eccentricity. A kindly disposition, full of tolerance and sympathy, avoiding polemics, who "never argued, but simply stated," containing so much that differed from other men that he was apt to be misjudged, but judged aright he was "an interesting, unique, and lovable personality." This memorial was ordered to be entered upon the minutes of the Academy.

Dr. Traill Green, of Easton, read a paper on "*The Imperfection of Technical Studies as a Means of Mental Culture.*" The central thought of this paper was that a man ought to know his tools and how to use them before the practical application of them to his life-work. When the natural sciences were born, physicians were true to their training, and assisted. If the study of the sciences be the *only* way to produce educated men, true education is of a very recent date, and all the worthies of a past age in philosophy and mathematics, in law and theology and medicine, were without a true education. The schools of technology are beginning to recognize the need of a general preparatory culture before entering upon technical studies, asserting that they are post-graduate schools. Allusion was made to the address of Charles Francis Adams, Jr., and quotations made, showing that false deductions had been drawn from it, and the necessity for a full and rounded development of the faculties as a preliminary to professional study was claimed to exist.

Dr. Benjamin Lee, of Philadelphia, read the next paper, having the title "*The Value of an Acquaintance with Botany as a Preliminary to the Study of Medicine.*" The paper consisted, first, of an historical study of the earlier botanists of the country, many of them being connected with the medical department of the University of Pennsylvania. Reference was made to the bibliography of American medical botany, the value of our native vegetable *materia medica* alluded to, and the almost utter ignorance of it on the part of physicians, leaving its development almost entirely to manufacturing pharmacists. There is an admirable opportunity given to country practitioners to study the indigenous vegetable *materia medica*, which is generally neglected because of ignorance. This study, if

not begun during student life, will probably be neglected afterwards. The action of the Medical Society of the State of Pennsylvania, in placing botany among the subjects of preliminary education, was noticed with approbation.

"*Is it Fair?*" was the rather fanciful title of a paper by Dr. Charles McIntire, Jr., of Easton. The sub-title explained that it was "A Study of the Comparative Political Position of the United States." Assuming that theology, law, and medicine were all of them learned professions, one would judge that equal legal protection would be given them; but examination shows that this is not so: that while the rule requires a special examination of the members of the other professions apart from their college or technical school examination, in medicine this is not the case; and to this condition the author appended the question, "Is it fair?" Suggestions as to the cause of this condition were to be found in the nature of the physician's calling and the indifference of the profession.

The last paper of the afternoon was by Medical Director Gihon, U.S.N., entitled "*The Higher Plane in Medicine.*"* In this paper the author pointed out some of the glaring defects of our present system of teaching, and demanded their correction.

The evening session was given to hearing the address of the President, Dr. Marcy, of Boston, who had selected as his subject "*The Recent Advances of Sanitary Science; the Relations of Micro-Organisms to Disease.*"

After expressing his thanks, and congratulating the Academy on its continuous prosperity, he entered upon the topic of his address. Differences of opinion have existed and will continue to exist, but, other things being equal, the better trained and better equipped soldiery will win. Rationalistic medicine exists alone without rivals, while *isms* or *pathies* will cease to be. There is a twofold duty for the physician, and the first is the prevention of disease, cure occupying a secondary place. Sanitation can hardly be called a science as yet. Much of what we deem modern was in use by those of the olden time. Hippocrates framed a wise maxim in "pure air, pure water, and a pure soil."

The discussion of the problems of life is not only instructive but fascinating. Mohammedanism, at least, is commendable in its provisions for cleanliness and careful living. The plagues of the Middle Ages would now be classed among the filth-diseases.

The best definition of health may perhaps be expressed in a hypothetical equilibrium between waste and repair exercised by the vital processes. The safe removal of the waste and worn-out material is one of the chief factors of sanitary science, and as the number of individuals gathered together increases, so does the complexity of the prob-

* This paper will appear in full in our next issue.—Ed. M. T.

TRADE MARK.

"EVERY SUPERIOR ARTICLE INVITES IMITATION."

MORITZ EISNER,

320 Race Street, Philadelphia,

SOLE AGENT FOR

Johann Hoff's Extract of Malt.

The undersigned, SOLE authorized Agent in the United States and Canada of JOHANN HOFF, of Berlin, Vienna, and St. Petersburg, for the sale of his well-known and valuable MALT EXTRACT, begs leave to call the attention of the profession specially to the fact that imitations of this Extract are offered for sale by various houses, and that Mr. Johann Hoff has instituted legal proceedings to protect his rights, and warns against any of these SPURIOUS IMITATIONS.

A BILL IN EQUITY HAS BEEN FILED BY MR. JOHANN HOFF IN THE CIRCUIT COURT OF THE UNITED STATES, for the Southern District of New York, AGAINST TARRANT & CO., of that city, to punish them for their violation of Mr. Johann Hoff's rights in the past, and to restrain them from such conduct hereafter.

For the protection of the public against imposture, the undersigned will have a label pasted on the neck of every bottle bearing the signatures of "Johann Hoff" and "Moritz Eisner," Sole Agent for the United States.

New Remedies, Chemicals, and Alkaloids,

RECEIVED FROM

H. TROMMSDORF, in Erfurt.

BUTYLCHLORALHYDRAT, HYOSCYAMINE, CURARIN,
 BROMALHYDRAT, RESORCIN, PROTOIN,
 SODÆ ETHYLATE, CONINE BROMIDE,
 CAFFEINE VALERIANATE, JALAPIN, ELAYLCHLORÜR,
 DUBOISINE SULPH., THYMOL CRYST., BROMOFORM,
 ESERINE SULPH., CODEINE, HYDRIODIC ACID,
 HOMATROPIN HYDROBROM., SULPH. AND MURIATE OF BERBERIN.
 PILOCARPIN mur. nitr. salicylate and sulphate.
 KOUSSIN, UREA NITR., PELLETERINE PURE.

Prices quoted at the lowest rates, upon application to

MORITZ EISNER, No. 320 Race St.

None genuine without the signature of
 M. EISNER, 320 RACE ST., Sole Agent
 for the United States, on every bottle.

BEWARE OF IMITATIONS.

A GOLD MEDAL
TO
W. H. SCHIEFFELIN & CO.
OF NEW YORK.

“At the Holland International Exhibition at Amsterdam a GOLD MEDAL has just been awarded to Messrs. W. H. Schieffelin & Co. for their SOLUBLE PILLS AND GRANULES.

“This is a special distinction for their reliable preparations, as the award was made after a careful analysis of specimens of Messrs. Schieffelin’s manufactures by prominent chemists.”—*Medical Record*, New York, Sept. 22, 1883.

lem increase: hence this age of steam, by permitting greater aggregation of men, greatly enhances the difficulties of the problem.

The lecturer then considered the atmosphere and its impurities, more especially those products of organic decomposition, the so-called disease-germs and lower forms of life. Many of these are visible in the air, such as are revealed by a beam of light, as first shown to us by Tyndall.

The impurities in water, especially the lower forms of life, were next discussed, and particular attention was called to soil-pollution, and to the fact that after a while the soil does not purify. The importance of the study of the sources of septic poisoning was inferred from the fact that a greater number died in the army during the late war from zymotic diseases than from wounds. It will not do for physicians to be blind to these things, but the rather disseminate among the masses proper instruction of the cardinal virtues of right living, and use every means in our power for the enactment and enforcement of wise sanitary laws, so that rich and poor alike will be abundantly supplied with pure air and water and have their habitation upon an uncontaminated soil.

At the last meeting a resolution was adopted authorizing a subscription collation to be partaken at the close of the annual address, which was carried out at this time, greatly aiding in giving good fellowship and pleasant acquaintance among the Fellows.

On Wednesday morning the council recommended the following gentlemen for Fellowship: Dr. P. A. Morrow, New York; Dr. Herman Knapp, New York; Dr. W. S. Todd, Ridgefield, Conn. They also nominated to honorary Fellowship Dr. J. Marion Sims, of New York. These gentlemen were all elected.

The nominating committee presented the following report:

For President.—Dr. Benjamin Lee, Philadelphia.

For Vice-Presidents.—Dr. A. L. Gihon, U.S.N., Washington; Dr. Nathan Allen, Lowell, Massachusetts; Dr. G. F. Shrady, New York; Dr. E. J. Birmingham, New York.

For Secretary and Treasurer.—Dr. R. J. Dunglison, Philadelphia.

For Assistant Secretary.—Dr. Charles McIntire, Jr., Easton, Pennsylvania.

Place of next meeting.—Baltimore, Maryland.

The report of the committee was received, and the several nominations were unanimously confirmed by ballot. The first paper of the morning was by Dr. L. S. Pilcher, of Brooklyn, on "*The Relations of Medical Journalism to Higher Medical Education in America.*" Dr. Pilcher discussed some of the papers of the previous day as a preface to his paper, since his ideas of the character of the "higher medical education" were not in harmony with those of the essayists of the day

previous. Continuing with his paper, the doctor called attention to the unrest, the fermentation that had been going on in the world of science for the last twenty-five years, in which medicine sympathized and with which she kept pace. The outcome of this was an elevation of the education of the average physician. Medical journals collected, assorted, utilized the material gathered by this investigation. The character of medical teaching has thus been revolutionized, and medical journals supplement the studies of the schools and constantly incite to a higher standard of medical education. The conclusions of Dr. Pilcher were reviewed and criticised by Drs. Steiner, Gihon, and Sibbet.

The next paper was by Dr. J. Cheston Morris, of Philadelphia, on the "*Milk-Supply in Large Cities,*" in which he spoke first of the importance of milk as an article of diet, the impossibility of improving upon its flavor or value by any artificial methods, and the constant necessity of having it absolutely pure and sweet. The present accepted plans of supplying cities with milk, and the difficulties encountered in delivering the milk in a good condition and of full strength, were discussed. The remedy proposed was to put the milk in bottles or jars at the farm, after carefully cooling the milk and stirring, so that the cream may be evenly mixed. These jars are sealed and sent in this way to the consumers. This method is no longer a mere fancy, but is practically and profitably worked by several farms near different cities. The importance of the subject may be determined when Philadelphia alone is estimated to expend about \$100 000 a day for milk.

"*The Exact Value of the Electrolytic Method*" was the title of a paper read by Dr. A. D. Rockwell, in which the author, by a careful examination of the effects produced by electrolysis upon the various organs and pathological conditions, was able to formulate to what use electrolysis might be put.

Dr. Dunglison then read the Annual Report of the Committee on Laws of Medical Practice in the United States and Canada. This committee has been at work for some time upon this subject, reporting yearly the changes that have taken place. The general tone of the report was one of encouragement. Our legislators are awakening to the fact that a physician should have certain qualifications for the calling he professes.

"*The Importance of Cleanliness in Surgical Operations*" was the title given to papers submitted by Dr. R. S. Sutton to the Academy and the American Gynecological Society, the papers being alike in name only. The doctor is inclined to the opinion that the evil influence of bacteria is exaggerated; many of them are harmless; but some are capable of causing septic poisoning, and, as in practice we cannot differentiate between them, all germs must be fought. This he prefers to do

by great care to secure absolute cleanliness. Indeed, the great good obtained by Listerism is brought about by the great cleanliness produced by the method. In the absence of Dr. Sutton, this paper was read for him by the Assistant Secretary.

For the same reason, Dr. Keyser read the paper submitted by Dr. Lewis P. Bush, entitled "*Some Thoughts on Vaccination.*" The objections to vaccination were thought to be frequently due to an imperfect or spurious vaccination being depended upon as protective, and because it failed to grant protection the whole plan was denounced. On this account, possibly, it would be best to have public vaccinators, who would be careful about the results. The disease smallpox is so loathsome in itself, entails such suffering and neglect upon those who are afflicted, and, should they recover, is so apt to disfigure them for life, that every means should be taken to put properly before the people the value and utility of vaccination thoroughly and properly done.

At the conclusion of the papers, Dr. Marcy pronounced his valedictory in a few but eloquent words, and appointed Dr. Keyser to conduct the President-elect to the chair.

Dr. Lee, in taking the chair, took refuge in the proverb "Still waters run deep," and, if his words were few, he felt deeply grateful for the honor conferred. He then appointed as additional members of council Dr. C. C. Bombaugh, of Baltimore; William Elmer, Jr., of Trenton; and J. Cheston Morris, of Philadelphia.

The Academy then brought its eighth session to a close, the attendance being larger than ever before, with an interest maintained until the hour of adjournment.

NEW YORK PATHOLOGICAL SOCIETY.

A STATED meeting was held October 10, 1883, George F. Shrady, M.D., President, in the chair.

The minutes of the previous meeting were read by the Secretary, and approved.

AMPUTATION OF THE KNEE.

Dr. Wackenheimer presented the parts entering into the formation of the knee-joint, removed by amputation recently from a patient suffering from arthritis. The patient, aged 52 years, two months before the operation observed slight swelling of the knee, which increased rapidly during the last three weeks. But very little pain was present. The examination of the specimen after amputation at the thigh showed that there seemed to have been recent hæmatoma; the head of the tibia and fibula had undergone rarefaction; pus was absent. The patient had been able to stand on the leg up to the time of the operation. He was now in good health; the temperature and pulse had fallen to normal.

The President referred to two cases which recently came under his observation, which fell under the head of the spinal arthropathies, and in which pain was scarcely a noticeable symptom. One of the patients was able to walk with perfect ease, except for twisting about of the affected knee.

OPERATION FOR STRANGULATED INGUINAL HERNIA.

Dr. Elliot presented the specimen, which was obtained from a young man, aged 19 years, who began to suffer from symptoms of hernial strangulation two days previous to his entrance into the hospital. Attempts at taxis had proved unsuccessful. During the past twenty-four hours stercoraceous vomiting had been present; the patient was unconscious; there were symptoms of partial collapse. The parts were found partially adherent to the walls of the sac, but not apparently gangrenous. But it was considered best not to return them to the abdominal cavity. The patient did not regain consciousness, but died within a day after the operation. There was found some clear serum in the peritoneal cavity, but no positive signs of active inflammation. The points of interest in the case were the descent of a congenital inguinal hernia and strangulation for the first time at the age of nineteen years; the fatal result without signs of active peritonitis; the possibility of recovery had the tumor been reduced.

Dr. Carpenter once operated for a strangulated direct inguinal hernia of five days' standing, or longer. The patient, however, did not recover from the shock. The tumor had been returned, although the propriety of doing so had been questioned. It was of interest to note that the physician who first saw the patient, taking the case to be one of indirect inguinal hernia, used taxis, with the result simply of increasing the size of the tumor by pushing the gut up the inguinal canal.

INOCULATION OF SCARLATINA POISON IN HORSES AND CHILDREN.

Dr. Peters reported progress from the committee appointed to investigate the question of scarlatina in horses. The report gave the results of attempts at inoculation made by Dr. Sickler. Two colts and one calf were experimented upon. The symptoms, developed with more or less uniformity, were the following: redness of the pharyngeal mucous membrane, swelling of the glands of the neck, rise of temperature and increased pulse-rate, discharge from the nose, eruption, restlessness. Seven children, all in families in which scarlatina existed, were inoculated either by introduction of blood or scarlatinal scales from a patient sick with scarlet fever, or by inhalation of the scarlatinal exudations. The result was rapid development of scarlet fever in all but one case, in which a few days first elapsed. The symptoms were mild, and

in but two cases did albuminuria appear. All recovered. Scarlet fever in horses was not generally recognized by veterinary surgeons in New York, but the disease was described in veterinary books, and was traced back as long ago as it was known to exist in man. It was not improbable that man first took it from the lower animals. A certain form of pink-eye, in which pinkness of the eye, however, was by no means uniform, was considered by Dr. Peters to be scarlet fever. In cases of doubtful origin in children, the possibility of the disease having been brought home in the clothing of the men from the livery-stables was not to be overlooked.

CEREBRAL SOFTENING.

Dr. Ferguson presented the brain, the seat of extensive softening in the right hemisphere, removed from a woman, 65 years of age, who had suddenly developed paralysis of the left side of the body, with difficulty in speech, after an extensive burn upon the chest, arms, and legs, from boiling water. The temperature, pulse, and respiration rose, and she died some hours after the injury. She was said never to have been sick before. The left ventricle was found hypertrophied and moderately dilated; the kidneys, the seat of extensive diffuse nephritis. The right side of the brain was extensively softened, especially in the parietal region; the ventricles dilated. The left hemisphere was normal. The tongue had also deviated to the left. Notwithstanding the extent of the kidney-lesion and the presence of numerous hyaline, granular, and fatty casts in the tubules, examination of the urine had proved entirely negative. There was no sign of embolism, thrombosis, or of hemorrhage, except very slight in the ganglia. The case had occurred too recently to admit of careful microscopic examination.

THE AMERICAN CLIMATOLOGICAL ASSOCIATION.

At a meeting of the profession called for the purpose, September 25, 1883, at the hall of the Academy of Medicine, New York, the American Climatological Association was organized, and forty names were enrolled as members.

The objects of the Association were stated to be the study of diseases of the respiratory organs, together with the influence of climate thereon.

A committee consisting of Dr. Tyndale, of New York, Dr. Bruen, of Philadelphia, and Dr. Garland, of Boston, was authorized to act temporarily as a Board of Censors, and to draft a constitution and by-laws, and submit the same at the next meeting.

The following officers were elected:

President, Dr. A. L. Loomis, New York.

First Vice-President, Dr. F. J. Knight, Boston.

Second Vice-President, Dr. W. H. Geddings, Arkansas.

Secretary and Treasurer, Dr. J. B. Walker, Philadelphia.

It was decided to hold the first annual meeting in 1884 at Washington either immediately before or after the meeting of the American Medical Association, for which the following were appointed a Committee of Arrangements: Drs. Alex. Y. P. Garnett, Washington, D.C.; F. Donaldson, Baltimore; F. Bosworth, New York; L. Shurley, Detroit; J. C. Wilson, Philadelphia.

REVIEWS AND BOOK NOTICES.

THE PHYSIOLOGICAL FACTOR IN DIAGNOSIS. A WORK FOR YOUNG PRACTITIONERS. By J. MILNER FOTHERGILL, M.D., Physician to the City of London Hospital for Diseases of the Chest (Victoria Park), etc., etc. New York, William Wood & Co., 1883. pp. 251.

To those who expect to find this volume anything more than an excellent manual of symptomatology, abounding in facts of value well set forth in the familiar style of the author, the somewhat striking title will prove misleading. Nevertheless it is a book to buy and read. A more formal arrangement and a more methodical treatment of some of the subjects would have enhanced its value as a work of reference. It is fresh, crisp, and suggestive on every page, in every line. In thirteen fluent chapters the author discusses the sick man and his sickness, and how the young practitioner is to obtain a useful knowledge of both. The (1) history of the family and the individual, (2) the external appearance, (3) the tongue, (4) the respiration, (5) the pulse, (6) the alimentary canal, (7) the urine, (8) the reproductive organs, (9) the temperature, (10) motor and sensory disorders, (11) the patient's sensations, (12) the patient in his bedroom, are treated of in the first twelve chapters in an instructive and often amusing way. The concluding chapter is wholly personal, and in it Dr. Fothergill disarms criticism of the rapidity with which his books appear, by promising for the future to devote his time to the revision and enlargement of his works and to getting out new editions. The present volume gives us the impression of having been "made" in haste. There are occasional inelegant expressions and some inaccuracy. In reading proof, *Torcula Hierophili* (p. 213) has been overlooked.

We cannot too heartily commend Dr. Fothergill's oft-repeated direction to diagnose the patient as well as the disease, which is in truth the watchword of the book, just as elsewhere he has manfully insisted that to treat the patient rather than the disease is the object of therapeutics.

J. C. W.

THE ROLLER BANDAGE. By WILLIAM BARTON HOPKINS, M.D., Assistant Demonstrator of Surgery in the University of Pennsylvania, etc. Small 8vo, 95 pages. J. B. Lippincott & Co., Philadelphia.

In the preface of this little work the author states that "each bandage was applied to a living model, and whenever the roller pursued a course which the author has found in his association with students was the cause of uncertainty, it was at once photographed." "From these photographs accurate drawings were made." This plan has relieved the book of the stereotyped plates which have done duty for so many years in works on bandaging, and gives an appearance of newness which is refreshing. With a few exceptions, the turns of the different bandages are distinctly portrayed by the method of illustration employed. In the drawing representing the application of Velpeau's bandage the hand is placed on the summit of the sound shoulder, instead of upon the acromion, as directed by Velpeau in his description of the bandage. The directions given for application of the bandages are clear and specific, and will be easily comprehended, we think, by students,—to whom the book will be a guide in the surgical room. J. E. M.

MISCELLANY.

DR. HENRY LEFFMANN, Professor of Chemistry in the Philadelphia Polyclinic, has been elected to the chair of chemistry and metallurgy in the Pennsylvania Dental College, which had been rendered vacant by the death of Prof. T. L. Buckingham.

DEATH OF ONE OF THE FRENCH CHOLERA COMMISSIONERS.—Dr. Thuillier, a member of the Pasteur Scientific Mission, died at Alexandria on Tuesday, the 18th ult., of cholera.

NOTES AND QUERIES.

THE LAST OF THE BARBED-WIRE BEEF-SKEWER.

MR. EDITOR,—At a recent meeting of the Philadelphia County Medical Society, Dr. W. R. D. Blackwood read a paper entitled "Remarks on the Chicago Beef Wire Skewer." This was also published in the *Medical Times*, October 6, 1883. Briefly speaking, the article may be divided into three paragraphs: the first and third treat of the mode of preparation, the shipment, and the superior excellence of the meat of a certain dealer. About this I have nothing to say, as it has no bearing on the matter of which I shall treat; but the second paragraph contains remarks which need to be referred to.

Some months ago, my attention was first attracted to the beef-skewers in question by several cases which came under my care, which was soon followed by a publication warning meat-consumers of this danger. The allegation that this was a sensational attack made on this variety of beef in the interest of a "clique of butchers" is not recognized, as I have not had the pleasure of being acquainted with such a body. This matter was at once thoroughly investigated by Messrs. Abner A. Jewitt & Co., wholesale dealers in Chicago dressed

beef, of this city. These gentlemen were so thoroughly convinced that it was not the work of a *clique*, also of the importance of preventing further danger from these skewers, that they at once ordered them to be removed and their use discontinued. This action certainly demonstrated that the danger was not a supposed one, but an actual one. As was the custom with exporters of Western beef, one barbed skewer was used on each quarter of beef to fasten the tag; this, of course, reduced the danger to a minimum; but when it is considered that a number of retail meat-dealers were also in the habit of using this variety of meat-skewer to fasten their business cards on every rib-roast, etc., that left their establishments, it can be understood that the danger was manifestly increased. It is needless here to speak of the great variety of foreign bodies which may find or have already accidentally found their way into the upper air and alimentary passages; the latest was the Chicago beef wire skewer, which we need no longer fear. Since the publication of my paper calling attention to the subject, its use has been discontinued, and it is now a thing of the past.

Very respectfully,

JOHN S. MILLER, M.D.,
Assistant in the Laryngological Department,
Jefferson Medical College Hospital.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM OCTOBER 6 TO OCTOBER 13, 1883.

HAMMOND, JOHN F., COLONEL AND SURGEON.—Leave of absence on surgeon's certificate of disability granted April 2, 1883, extended six months on surgeon's certificate of disability. Paragraph 7, S. O. 231, A. G. O., October 8, 1883.

SWIFT, EEBENZER, LIEUTENANT-COLONEL AND ASSISTANT MEDICAL PURVEYOR.—Under the provisions of Section 1 of the act of Congress approved June 30, 1882, is, by operation of law, this day retired from active service, and will proceed to his home. Paragraph 4, S. O. 231, A. G. O., October 8, 1883.

HARTSUFF, ALBERT, MAJOR AND SURGEON.—Granted leave of absence for fifteen days. Paragraph 2, S. O. 205, Department of the Missouri, October 6, 1883.

MEACHAM, FRANK, MAJOR AND SURGEON.—Assigned to duty at Fort Douglas, Utah. Paragraph 3, S. O. 109, Department of the Platte, October 6, 1883.

CRONKHITE, H. M., CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty at Fort D. A. Russell, Wyoming. Paragraph 3, S. O. 109, Department of the Platte, October 6, 1883.

WEISEL, DANIEL, CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty at Fort Fred Steele, Wyoming. Paragraph 3, S. O. 109, Department of the Platte, October 6, 1883.

ARTHUR, W. H., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to duty at Fort Douglas, Utah. Paragraph 3, S. O. 109, Department of the Platte, October 6, 1883.

STRONG, NORTON, FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to duty at Fort Washakie, Wyoming. Paragraph 3, S. O. 109, Department of the Platte, October 6, 1883.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY FROM OCTOBER 6 TO OCTOBER 13, 1883.

Surgeon F. L. DU BOIS detached from Naval Rendezvous, Philadelphia, and ordered as member of the Medical Examining Board, Philadelphia.

P. A. Surgeon CHARLES W. RUSH detached from the Naval Hospital, New York, and ordered to the receiving-ship "Colorado," New York.

P. A. Surgeon M. D. JONES detached from the Naval Hospital, Washington, D.C., and ordered to the Naval Hospital, New York.

P. A. Surgeon RICHARD ASHBIDGE detached from the Naval Academy, and ordered to the U.S. steam-ship "Swatara."

Surgeon THOMAS HILAND granted leave of absence for one year, with permission to leave the United States.

Surgeon WILLIAM J. SIMON and **P. A. Surgeon M. H. CRAWFORD** ordered to report on November 1 for duty on board the U.S. steam-ship "Trenton."

PHILADELPHIA MEDICAL TIMES.

PHILADELPHIA, NOVEMBER 3, 1883.

ORIGINAL LECTURES.

THE HIGHER PLANE IN MEDICINE.

BY ALBERT L. GIHON, A.M., M.D.,

Medical Director U.S. Navy, Fellow of the American Academy of Medicine, etc.

Read before the American Academy of Medicine, at its Annual Meeting, held in New York, October 9, 1883.

IF ever there was a time when the letters M.D. appended to a man's name rightly signified that he was *doctoratus in arte medica*, there can be no doubt, in this day, that want of skill in the *art* is too often supplemented by a profound ignorance of the substantial groundwork on which is reared the superstructure of the *science* of medicine.

Of the more than ninety thousand regularly graduated orthodox medical practitioners in the United States how many there are whose horizon is upon this level! That the proportion of those who never enter the temple at all, but hang upon its purlieus, is alarmingly great; no Fellow of this Academy will contest; the prominent object of its organization being the encouragement of young men to "pursue regular courses of study in classical and scientific institutions before entering upon the study of medicine." The furtherance of this object—by calling attention to that higher plane on which so few stand, but where all should stand—is all I propose in the few minutes I will occupy of your time.

Remedies for defective medical education have not been lacking. The urgency of the need has been set forth by the journals of the profession, and in the State and National Associations. Before, however, attempting to scourge the money-changers out from the temple of the true faith, it may be profitable for us to ask ourselves, "Why are they there?" Possibly we may find that the rank and file are less to blame than the leaders who have not led, the standard-bearers who have trailed their ensigns in the dust, the sentries who have slept on picket-duty. It may be, too, that you and I have left undone the things we ought to have done.

In the popular view, doctors are men (and women) who cure sick people, heal their sores, mend their broken bones. They are graded chiefly by the kind of houses and localities in which they dwell, the style

of their equipages, and the size of the fees they are recognized as having a right to demand; but corn doctor and horse doctor, eye doctor and woman doctor, are all made members of the same guild. "Pills" is the sobriquet both of the assistant surgeon and the surgeon of the fleet, as well as of the loblolly-boy and the apothecary on the berth-deck. "Knights of the scalpel," "Galen's Guards," or, with broader alliterative witticism, "Physickers and fee-seekers in council," are terms judged appropriate to designate in the public prints the annual assemblies of the representative body of the profession. The barber and the leech do not, it is true, any longer share titles and functions, but the old woman who mixes a poultice and the gold-spectacled savant who writes a prescription are recognized as having one and the same vocation.

Is the public only to blame for this low estimate of the profession of medicine? Are the tyros who swell its numbers themselves culpable, that they stand in the crowd so far below the plane of the elevated physician? If not these, who then?

I do not think there can be any question that medicine is regarded both by the people and the many physicians themselves as a money-making occupation, rather than as a scientific study engrossing the highest faculties of the mind,—this, in the case of physicians, because the young men who embrace it as a profession have been accustomed from the beginning to look only at its trade aspect. Physicians, like other mortals, must be fed, clothed, and domiciled to exist at all, and they apply their knowledge to the needs of humanity with the hope of gain, that they may be able to buy the all-important food, clothes, and habitations; but they are apt to lose sight of the fact that this is only the practical application of information acquired in the study of a grand science,—that the relief of individual suffering is an incident in the broader problem of the protection, development, and advancement of the human race. They keep their eye fixed on the smaller object of the sufferer of the moment, instead of ranging their view over the whole field of human existence. So far as the ailing Jones and his wife are concerned, their pains and aches are of far more moment than the origin of species, the nature of the *vis vita*, or the mysteries of cytogenesis; and they may be pardoned for preferring the quack, who

mystifies them with a lie and soothes them with a panacea, to a Flint or a Paget; but do not let us forget that the ability to relieve pain and banish tears is the outcome of the study of complex organisms through long stages of evolution and of mysterious vital phenomena, involving diligent application, profound research, and the highest efforts of the reasoning powers. Especially do not let those of us who assume the office of instructing the young err in giving them the impression that the only aim of medicine is to straighten a broken limb or check a diarrhoea. There is no higher plane of thought or action for one who has been fed at this font. He matures in the stage of arrested development, content to wallow in the slough of professional ignorance, and a lucky combination which multiplies fees will interest him more than the discovery of a microbe which suggests infinite possibilities.

Properly enough, the bones are the medical student's professional alphabet, though I am not quite sure that a developed human bone is the correct alpha. Quite as often, however, volumes of practice in the preceptor's library are read *pari passu* with the anatomy, and prescriptions are learned by heart *before an idea has been formed of the organs and functions their constituents are designed to affect*. Possibly the preceptor, with intended kindness, exhibits cases, takes the youth on a round of visits, or intrusts him with some minor responsibilities which have the effect of diverting him still more from that slow systematic grounding in the principles of medicine which should precede the knowledge of the name of a single disease or of a single remedy.

From the preceptor's office, where the tutelage is often as nominal as the duration is short, the embryo office-student becomes the college-larva, and the same food is fed to him. On the benches of the amphitheatre first-course students watch an operation or get a veneering of slap-dash diagnosis, though as ignorant as their mothers of the meaning of the curious terms they are hearing for the first time.

Finally, the youth goes through the farce of being graduated, with a stock in trade consisting of a list of imaginary entities labelled as diseases, and of a corresponding list of antidotes in the shape of remedies and prescriptions, and with this begins his career,—fortunate if before his neatly-gilded sign loses its glare he recognizes a

fever which he knocks in the head with the appropriate bludgeon, or encounters a broken bone which he successfully straightens, or a pleurisy which he manages to blister, purge, and sweat into a longer or shorter convalescence. But what can he really know of that marvellous mechanism called man? What of that great scheme of organization beginning with the individual monads and culminating in that aggregation of them called Cuvier? What of cell-growth, development, transformation, migration, and the struggle for existence against hordes of warring bacteria? What of evolution and correlated forces, of man's place in the Kosmos, of the laws of life, and the realities and possibilities of the material organism, and those immaterial psychic influences by which it is governed and controlled?

How should he? Was he ever taught by his preceptor that medicine is a science, demanding the exercise of the intellect, based upon an intimate acquaintance with the inanimate as well as the animate world, finding its source in every other branch of human knowledge, concerning itself about man's place in the universe, his origin and his destiny, his present well-being, his happiness, his prosperity, and his permanence?

At college what prominently attracted his attention?—professorship after professorship of practical branches,—Surgery, Practice, Obstetrics, Ophthalmology, Otology, Laryngology, Dermatology, Gynæcology, Diseases of the Throat and of the Nose, of the Respiratory Organs, Mental Diseases, Venereal Diseases, Diseases of the Brain and Nervous System, Diseases of Children, and Diseases of Women. Even at Harvard, Clinical Medicine and Clinical Surgery crop in upon the second year. One course is enough; and the student,—whether it be a young man from an academy or from his father's farm, or a middle-aged man who has found piano-tuning unprofitable or wearied of confinement at a clerk's desk,—with a general idea of his anatomical interior, a vaguer conception of the functions of its enclosed organs, detesting the chemistry which he has skipped or has heard without understanding, and dangerously wise in drugs, plunges into Special Pathology and Special Therapeutics in his second year,—like a child into a mud-puddle,—and soon talks glibly of symptoms, when he knows nothing

of their pathological significance, and of treatment, though profoundly ignorant of the physiological effects of his doses.

Naturally, one result of this early mini-fying process of concentrating the mind exclusively upon the immediately practical aspects of medicine,—this looking at its study through the small end of the telescope until the eye becomes unable to recognize the wider view unfolded by the other,—this conception of it solely as a money-getting occupation,—is the fruitful cause of the development of petty rivalries of business and contentions over the loaves and fishes. The cordial, graceful amenities of a fraternity of scientific investigators are supplanted by the narrow spirit of exclusiveness which characterizes trade organizations.

At the recent meeting of the American Medical Association I had occasion to read a paper before the Section in State Medicine, in which I undertook to establish that a higher medical education was the fundamental fact in medical ethics. I quoted from the records of the Naval Medical Board of Examiners, of which I had been a member, numerous instances of scandalously defective education on the part of regular graduates of the most reputable orthodox schools, who had presented themselves for admission into the medical corps of the navy. As these will be published in the Journal of the Association, I need only cursorily mention them here. These were M.D.'s whom it were folly to expect to rise to that higher plane which it is my present object to insist is the proper level of the profession. Most of them were only fit to claim fellowship with the old women and the male cot-betties who are its camp-followers. What, for instance, is the place in the medical commune of that M.D., who was of unassailable regularity and unquestionable orthodoxy, who deliberately demonstrated the spermatic cord in a female subject? or his, who, having attempted a disarticulation through the tarsus, declared that he would allow the protruding cuneiform bones to remain until they skinned over? or of that one, who treated orchitis by removing one or both testes if the inflammation should not subside after rest, cold applications, and occasional anæsthetics? or of that other, who defined "pneumonia" to be a peculiar disease affecting one lung and "pleurisy" the

name given to it on the other side? or of the worthy, who advised cauterization of the soles of the feet in congestion of the brain, using the actual cautery for poor people, and the potential cautery, by which he meant nitrate of silver, for rich patients, that they might not be incommoded by the smell of the burning flesh? or his, who said he would trephine for fracture at the base of the skull? or his, who not being able to sweat his puerperal woman with Dover's Powder gave her hot tea and a Russian bath? or his, who accelerated the expulsion of the placenta by walking his labor case about the room, five minutes being allowed to elapse after delivery before he required this exercise? I have no reason to believe that these instances are exceptional. I can parallel them with equally flagrant cases among men who would have spurned the suggestion of becoming a "navy doctor," two which just occur to me: one, a surgeon of local reputation, who was about to operate for an ovarian tumor in a case I was asked to see by the mother, and whose labor was saved him by the introduction of a catheter in the lost meatus; the other, who had encased a young girl in an irksome and cumbersome apparatus for fracture of the clavicle, when an examination on my part (unethical, I admit), in her grandfather's study, revealed no solution of continuity whatsoever. These men were all found wanting in simple practical matters. What if the examiners had ventured to question them about biological phenomena, about solidistic and humoral pathologies, or general considerations as to the nature of lesions of nutrition, or that well-gnawed bone of contention, fundamental methods of cure? Could the M.D. who defined "coxalgia" to be inflammation of the coccyx, "potable water" to be water that can be carried, "pneumothorax" to be a collection of pus, "acupressure" to be pressure by the finger or any other instrument, and "cholera communis" to mean *communicable cholera*, have ever understood the meaning of ordinary English terms sufficiently to have read intelligently a treatise or comprehended a lecture on pathological principles?

The subject of higher medical education is not a recent agitation. I have heard it argued ever since I was out of my own professional swaddling-clothes; but, beyond admissions of its need, confined to cer-

tain carefully-generalized statements as to insufficiently-prepared physicians, and the efforts of a few independent medical schools to extend their curricula, there has been nothing definitely asserted or instituted. No reform, however, has ever been accomplished, especially in this country, when it has been supported by mere abstract statements. Facts and figures that cannot be disputed are the granite foundations on which the new edifice must be erected. Yellow fever is only dreaded when your neighbor dies of it. Syphilis is deplored, like murder and highway-robbery, as a thing foreign to our own virtuous stronghold, until we see some gentle maiden guiltlessly contaminated, and we begin to calculate the millions of dollars the plague has cost, and see how communities have been decimated by the venereal scourge. Hence neither the public nor the profession will be satisfied that there are so many arrant fools who go about legally authorized to append M.D. to their names until the fact is thrown before a calcium light upon a screen, where all who run may read. I have quoted from the records at my command, with no desire to exalt those who have successfully passed the ordeal, but to show conclusively what manner of men are able to become legitimately possessors of degrees from schools of the first rank.

Of eleven hundred and forty-one candidates examined for admission into the medical corps of the navy during the past twenty years, only thirty-two per centum were accepted. I do not mean to claim any superexcellence for the fortunate (or unfortunate, if you prefer) three hundred and seventy. Doubtless many of these might also have properly been refused. Possibly there were among the unsuccessful seven hundred some who would have been found acceptable by other examiners, or who were victims of circumstances which obscured their merits or occasioned them to be unjustly treated. But were there only five hundred not fit to wear the professional toga, the inexorable logic of figures would be enough. Were there only one hundred shown to be invested with a dignity to which they were not entitled, the case would have been proven. Within the limits of a twenty-minute paper, I introduced twenty-five such, all of them graduates in medicine from schools of acknowledged orthodoxy, who out of their own mouths and by their own hands de-

monstrated not only their unfitness to practise the art of medicine, but their original incompetence to enter upon its study; and this I think as worthy your attention as the former, for, this established, the other is its necessary corollary. Can it be conceived that the graduated physician who "respectively" addressed his application to the "Navel Medicle Bord" was ever able to comprehend the description of the anatomy of the simplest bone? Whatever his natural ability, could such terms as *foramen* or *sulcus* or *condyle* or *apophysis* convey to him any better idea of their significance than so many French or German words? Pertinent here, let me say I had written this sentence when a certificate of the death of a friend and colleague was sent me by the family from his attending physician, written in a school-boy scrawl, interspersed with periods and other punctuation-marks where they had no place, with orthographical blunders of which "exhertion" and "attendent" and "enfeeble condition" are samples, beginning "To whom it may concerned," but wound up with a bold, rotund, unmistakable M.D.,—a production so illiterate that I was ashamed to file it as the work of a professional *confrère*.

President Johnson is said to have remarked to Judge Black, when the latter quoted the intolerance of the populace who cried, "crucify" the Christ, as an argument that the *vox populi* is not the *vox Dei*, "Remember that we have had the advantage of eighteen centuries of enlightenment." Mr. President and Fellows, remember your own twenty-five or thirty years of experience, or rather try to forget them, and place yourselves in the position of that uneducated youth or man who, when a full-fledged doctor, wrote "blud," and "orful," and "scassity," and "inturlec," or that one who came from Vermont, "wher" he "*studed Latin grammer*," or that other who did not come from Massachusetts, but who declared that "Plymouth was settled by Columbus, who gave the town its name,"—see with their eyes and listen with their ears, for an hour, to a description of the sutures and foramina and processes of the temporal bone, the origin and insertion of muscles and fasciæ, the coursing of nerves and vessels through it and by it; then pass with them for another hour to the chemical lecture-room, where equivalences and reactions are discoursed

about in almost another language, as foreign to them as the anatomist's; thence go with them to be instructed in the etiology, symptomatology, and pathology of enteric fever, where every other word is veritable Greek, and the clinical thermometer exhibited is the first thermometer of any kind they have ever seen. Yet here for the first time the novice thinks he stands on solid ground. He has sunk deep in the mire of anatomical terms; he has skirted clear of the quicksands of chemistry; he has made a hop, skip, and jump over the "bot-tony" of the materia medica; he has been wearied by the physiologist, and bewildered by the generalizations of general pathology; but in the clinical lecture or the amphitheatre he gains what he thinks is medical knowledge: he learns that quinine is a sheet-anchor and does not inconveniently kill; he sees a sore throat swabbed out by caustic, though he notes the one as "soar" and the other as "luner," and he hardens his heart to the necessary sticking-point after he witnesses a few jets of arterial blood.

Fellows of the American Academy of Medicine, it is not enough for you to organize "to encourage young men to pursue regular courses of study in classical and scientific institutions before entering upon the study of medicine." It is not enough to declare that it is *desirable* that matriculants shall possess a knowledge of the structure and uses of language and of the fundamental principles of natural science. You have got to say emphatically and publicly that these are essential, absolutely essential; that medicine cannot be intelligently studied without them; that Latin and Greek derivatives must be understood, else not only the nomenclature but the vernacular of the anatomist alone cannot be comprehended.

Os uteri and *os innominatum*, *quadriceps extensor femoris* and *sterno-cleido-mastoideus*, *tunica vaginalis* and *latissimus dorsi*, are no greater stumbling-blocks than common adjectives, like cancelled, reticulated, laminated, cutaneous, peripheral, or ganglionic. Is it or is it not a fact that a course of lectures on medical chemistry, which is simply chemistry in its relations to medicine, necessarily presupposes the preliminary knowledge of chemical principles? If it is, then say that neither the country bumpkin nor the city clerk can listen for the first time to disquisitions about atoms and molecules, oxides and suboxides and peroxides, phosphates and phosphites and

hypophosphites, and gain a single salutary idea. Can physiology be understood at all without a prior understanding of the facts of physics? Is it possible for the youth, whatever his natural parts, to master the phenomena of calorification, respiration, circulation, of absorption, nutrition, or secretion, and know nothing of the forces of nature that influence animate as well as inanimate matter? Can he hear of annual and perennial, of indigenous and exotic plants, of stamens and pistils, corollæ and petals, corms and rhizomes, and not be lost in what can only be to him a jargon of strange sounds? At this day, Hygeia can no longer be denied her place among the deities in our temple, but who can master the elementary laws of sanitary science if ignorant of the composition of the atmosphere, of heat and moisture, evaporation and condensation, of electricity and magnetism? What was the understanding of natural phenomena as a pupil of that "doctor in medicine" who said that "the boiling-point of Fahrenheit is about 300°, that of the centigrade scale not so high, and that of Réaumur higher," that he "could not tell what the zero of Fahrenheit was without having the other scales before him," and that "the natural temperature of the human body is from 112° to 140°"? or his, who defined the difference between electricity and galvanism to be that "one is the substance itself and the other its use"?

It is a common plea that bad spelling is not inconsistent with profound acquirements, and, while I admit that phonetic faults in English orthography are sometimes even commendable, I do not believe that those doctors, however regularly graduated, who wrote about *drams of lodnum* and *aurora epileptica*, who described the symptoms of *superation* and the treatment of *fishers of the anise*, who in one breath denounced *homeopaths* and in the next boasted of being a "reg'lar alleepath," were ever fit to be matriculated, or that any school that matriculated them deserved recognition. I have offered only evidence for which I can personally vouch, but I know from members of the Army Medical Board, of the Board of Examiners for the Marine Hospital Service, of the Illinois State Board of Medical Examiners, and the Secretary of the State Board of Health of West Virginia, that they can match anything I have adduced.

Nevertheless, when, aiming at an effective and immediate advance in medical education, I offered a series of resolutions at the May meeting of the American Medical Association, to which I sought the endorsement of that body, I failed to get even the Section in State Medicine to report them,—objection being made, not to the soundness of my position, but to the *expediency* of taking action. While the result was discouraging, I cannot say it was unexpected, former experience in reform movements having shown me that the antagonism of those interested in maintaining an abuse, and who hide themselves and stifle opposition by the gagging-process of a motion to lay upon the table, is scarcely more effective than the timidity or downright cowardice of those who applaud your motives but tie your hands with manacles of inexpediency. Two of the resolutions had the special object of excluding illiterate, ignorant, and incompetent graduates from the profession and from membership in its national representative body. A third, and the most important, urged upon the several legislatures the establishment of State Boards of Medical Examiners, whose certificate should be necessary to the issue of a license to practise, and upon “the authorities of every regularly-organized medical college in the State [which does not already require them],—first, the requirement of a proper preliminary education of matriculants, and, second, greater care in ascertaining the fitness of candidates for a degree.” In this Academy, at least, no argument is necessary to establish the need of a matriculant being able to read, write, and cipher, and to comprehend enough of the etymology of Greek and Latin derivatives to gather the meaning of the technical language of the profession; while the flagrant mistakes of so many graduates, which would be ludicrous were they not appalling in their possible consequences, are proof enough that some action is necessary in the way of establishing disinterested boards of examiners for degrees, in view of the lamentable fact that men, themselves able and educated, thoughtlessly affix their names to diplomas that are lies from beginning to end.

One other proposition in connection with graduation I offered merely as a personal suggestion,—to wit, “Medical colleges should confer upon graduates the degree of *Bachelor in Medicine*, such grad-

uates to be eligible to the degree of *Doctor in Medicine* at the end of three years, after having given satisfactory evidence of their qualifications to the Board of Censors of the State Medical Society.”

Time works its own reforms. There is no *retrosum* in this world. A new and better order of things is certain to be evolved. But shall we wait for the slow process of natural development? The sunrise comes, but ere “the dew-drop slips into the shining sea” shall we not see something of the light? Let us water the tender plant, feed its roots, and hope to gather its first fruits.

In a recent number of the *New York Medical Journal* there were published the annual announcements of sixty-seven non-sectarian medical colleges in the United States and Canada, recognized by the Illinois State Board of Health.* These aggregate seven hundred and eighty-seven professors or members of faculties, including forty-eight emeritus, retired, or honorary professorships; five hundred and thirty-nine assistant and adjunct professors, lecturers, instructors, demonstrators, prosectors, and examiners, a total of thirteen hundred and twenty-six; an average of twelve in each faculty, and a total of twenty teachers in each school, ranging from the modest staff of five of the University of Virginia, to the corps of sixty-four at the College of Physicians and Surgeons of New York, fifty-four at the Medical Department of the University of New York, fifty at the Medical Department of Harvard University, and forty-three at the Medical Department of the University of Pennsylvania, and at Bellevue. The chairs in many of the schools are so interlinked that it is almost impossible to group them in tabular form, *Materia Medica* being handicapped with Ophthalmology and Diseases of Children, Chemistry with Diseases of the Nose and Throat, Obstetrics with Psychological Medicine, Physiology with Venereal Diseases, and Ophthalmology with Histology and Pathological Anatomy. It is worthy of remark that in but one instance

* Since the date of this paper, the Illinois State Board of Health has published its admirable and valuable report on “Medical Education and the Regulation of the Practice of Medicine in the United States and Canada,” giving full details of the medical laws and institutions in the several States, Territories, and Provinces of the two countries. From this it appears that of 218 colleges accounted for 130 are still in existence (119 American, 11 Canadian), of which 85 are recognized by the Illinois State Board. Of these 6 are in Canada, all regular, and 79 in the United States, 63 regular, 11 homœopathic, and 5 eclectic. Nine other irregular American colleges have a conditional recognition.

is Comparative Anatomy mentioned as a subject of study, and then only as a lectureship, shared with General Anatomy, in the Miami Medical College, of Cincinnati. Another friend of our early days, the "Institutes of Medicine," finds special place in two Canadian and three American schools,—viz., the Jefferson Medical College of Philadelphia, the Albany Medical College as an emeritus chair, and the Medical Department of the Arkansas Industrial University, at Little Rock. Hygiene, after struggling for existence as an adopted child of Physiology, is now dignified as a professorial chair in twelve schools, as an adjunct professorship in one other, and in three as a lectureship; while in other nine it is still tied to the maternal apron-string of Physiology.

Of the sixty-one colleges in the United States, twenty-one require a preliminary examination, or the evidences of preliminary education; * seven of these, however, only vaguely exacting "satisfactory evidences" of it. The other fourteen explicitly prescribe a matriculation examination, or the possession of a degree or certificate of some academic institution; and perhaps I may be pardoned, as one of your Junior Fellows, for suggesting that the letter of our Constitution excludes from Fellowship men entitled to it by their literary, classical, and scientific acquirements, who have failed, sometimes from trivial causes, to become possessors of a formal degree. If this alone is exacted, how can we consistently deny the same weight to the degree of M.D.?

Four Canadian and twelve American colleges announce their adherence to the requirements of the Illinois State Board of Health, and seven require the final examinations to be in writing.

Likewise the point of the wedge of reformation has been driven into the curricula. The College of Physicians and Surgeons of New York recommends a third annual course; the Michigan College of Medicine, of Detroit, has a freshman, a junior, and a senior year, and restricts all clinical instruction to the last year; the University of Pennsylvania has an obligatory course of three years, and adds a voluntary fourth; and Harvard requires three years and recommends four.† Undoubtedly, if

what is thus recommended is commendable, it should be required, and Harvard insist upon its fourth year, the University of Pennsylvania make it obligatory, and Michigan substitute a sophomore for the present junior and extend the latter over a new junior and a senior year. Meanwhile, it has become the paramount duty of this Academy and of every other national medical association to lend these pioneers no lukewarm countenance, but to give them hearty, energetic, and efficient support.

A standard of preliminary education that will go far enough to embrace a knowledge of the natural sciences; a graded curriculum of four years; a rigorous examination for graduation by *disinterested boards*; a three years' baccalaureate probationary to the doctor's degree; all these are not enough, if preceptors, professors, and physicians, in general, fail to impress upon their pupils that medicine is something more than an art, seeking only to relieve individual suffering at so much a head; that its wider aim is to banish disease from the earth, prolong life, develop and improve the race, and thus increase the total of human happiness; that there is no grander or sublimer employment of the intellect than the study of man and his surroundings, catenated as it is with every other branch of knowledge; that he who is really learned in medicine is learned in many things, and moves in that higher plane which should be the aspiration of every man who presumes to add M.D. to his name. For those who are content to look no higher than the requirements of a daily routine, it would be better to make no pretence of education, but to recognize a class of general practitioners who can pull a tooth, apply a poultice, or chance a dose of calomel or castor-oil. Consign them to the *limbus fatuorum*, but do not claim for them equality and fraternity with EDUCATED physicians. The line must be sharply drawn. There can be no border-land. If the degree of M.D. is to be presumptive evidence of professional ability, see that it is the exponent of something definite. Repudiate sham colleges and sciolist teachers, and relieve the profession from the burden of the gross ignorance, illiteracy, and incompetency which are now its opprobria.

* Fifty-five regular colleges in the United States and ten in Canada are reported as "now exacting a preliminary education as a condition of matriculation."

† Fifteen regular American and ten Canadian colleges are

reported as "now requiring attendance on three or more courses of lectures before graduation," and fifty-six regular, seven homeopathic, and three eclectic as "recommending and providing for, but not requiring, three or more courses of lectures before graduation."

ORIGINAL COMMUNICATIONS.

REPORT ON THE PROGRESS OF
OPHTHALMOLOGY.

BY ALBERT G. HEYL, M.D.,

Ophthalmic Surgeon to the Episcopal Hospital.

THE NATURE OF THE JEQUIRITY OPHTHALMIA.

THE results of the investigations of Prof. Sattler with reference to the existence of a vegetable ferment in the jequirity infusion are of great interest by reason of their bearing on the germ theory of disease, as well as the attention which the remedy is exciting among ophthalmologists. A few points can only be alluded to. The jequirity bean itself possesses no principle capable of exciting the peculiar inflammation of the conjunctiva which occurs after the application of the macerated infusion. The effects depend upon a bacillus derived from the atmosphere, which finds in the albuminoid substance contained in the infusion the condition favorable for its propagation. An infusion which has been macerating for a day is filled with these bacilli. Higher temperature than 36° C. stops their development. The power of the infusion to induce an ophthalmia deteriorates by age, and finally ceases. The bacilli as they exist in the atmosphere are harmless; but in the jequirity infusion they acquire the physiological property of exciting the peculiar ophthalmia when brought in contact with the conjunctiva. [It is almost superfluous to say that these results have been attained with all the necessary precautions. H.]—*Klinische Monatsblätter*, August, 1883.

HEMI-ACHROMATOPSIA.

Swanzy reports a case of this form of defective color-perception. V in each eye = $\frac{6}{12}$; refraction of each eye slightly hypermetropic; optic nerve disks and retinae apparently normal; visual fields defective in the right upper quadrant. Holmgren's tests performed with accuracy. Testing the fields with colored wools resulted in finding the left half on each side totally color-blind. In the right half they could be detected, although the areas were concentrically contracted. Patient five months before had been seized with an attack of apoplexy; was unconscious twelve hours; in several days had completely recovered, excepting defective vision and confusion of ideas. Swanzy thinks

that this and similar cases (Landolt's, Samelsohn's, Bjerrum's) show that the nervous element in which the color-perception resides is in the brain, not in the peripheral visual apparatus; further, that the color-centre is distinct from that for form, sense, and ordinary light-perception.—*Lancet*, October, 1883.

[Granting that this patient's statements are to be relied upon, Swanzy's deductions seem hardly warranted. The most that this case shows is that consequent upon some intracranial disturbance the visual abnormality described occurred; it does not prove the location of the brain-lesion to have been a color-centre. The form of the color-defect is suggestive of the optic chiasm as the seat of the lesion, and perhaps the future history of the case will show it to have been one of progressive atrophy. H.]

INTRAOCULAR TENSION.

Schulten has examined the question of the elasticity of the sclera, and finds that at a pressure of 30–40 mm. Hg. it is very slight; for low pressures it is considerable. Post-mortem tension, as also in that of an enucleated eyeball, does not sink lower than 10 mm. The effect of the intraocular tension upon the flow of blood into the retinal and choroidal vessels seems to stand in a certain relation with the lateral pressure of the ophthalmic artery: when the intraocular pressure approaches the minimum of pressure of the artery, the flow of blood becomes intermittent; if the intraocular tension exceed the maximum pressure of the artery, the flow of blood stops.

The pressure of the ophthalmic artery is about that of larger vessels. The quantity of blood and the intraocular tension depend upon the lateral pressure in the blood-vessels of the eye, their tonus, elasticity, the quantity of liquid in the eye, and the external pressure.—*Arch. f. Ophthalmol.*, June, 1883. [It is not apparent in this abstract how the intraocular tension was measured:—probably by an instrument connected with the anterior chamber, as this is the method generally pursued. It is a fact, however, too little noted, that a distinction exists between the tension over the sclera and that over the cornea, and it is probable that the tension of the anterior chamber cannot be accepted as the real measure of the intraocular tension. H.]

TRAUMATIC GLAUCOMA.

Knapp reports the following case. Patient, æt. 29, was struck on R. E.; anterior chamber was absent, tension reduced, and myopia 5.5.D. A few days after the anterior chamber was restored, an attack of acute glaucoma was developed, which yielded to eserine. Sight was restored, and the myopia removed.—*Archiv f. Ophthalm.*, June, 1883.

A NEW INSTRUMENT FOR IRIDOTOMY AND DISCISSION.

Scherk, of Berlin, describes a needle for operating on opaque capsules or pupillary occlusions, such as occur after cataract-extraction. The instrument consists of a delicate shaft with one end fashioned into a small knife, similar to that of Knapp's discission-knife. The shaft fits closely in the handle of the instrument, like a trocar in a canula, and can be moved forward easily by the pressure of the finger on a button which projects from the handle of the instrument. The instrument is introduced into the anterior chamber and engaged in the capsule or iris as an ordinary needle; the button is pressed, the knife is pushed forward and cuts a hole in the tissue. [The principle upon which this instrument is based—of getting a maximum of cutting motion with a minimum of lever motion—is sound. The objection to the instrument is the canula device which is employed in its construction. H.]—*Klinische Monatsblätter*, August, 1883.

OPHTHALMOSCOPIC OBSERVATIONS AFTER HÆMATEMESIS.

Ulrich relates the following. Patient, a young woman, æt. 25, was very anæmic by reason of gastric hemorrhage. Seven days after the last bleeding, ophthalmoscopic examination simply showed pale disks. Two days later, fresh hemorrhage occurred, followed by a swoon. Ten minutes later, the eyes were examined: the disks were extremely pale, margins distinct, arteries small, with difficulty followed towards the periphery; veins normal as far as the sclerotic ring, where they suddenly lost their dark-red color and appeared of a bright red. This color-change depends on the relatively small amount of blood in this part of the veins. Close around the papillæ were numerous retinal hemorrhages, also some shining white plaques. The condition continued until the general condition of the patient improved, when she

was dismissed with $V = 1$, and visual field normal.

Hoffmann reports another case. Patient, a man æt. 47, was seized with several attacks of severe hæmatemesis. Two days after one of these attacks, complete blindness suddenly ensued, which, however, of itself slightly disappeared. Some weeks after, this patient came under observation. He was apparently in good physical condition; no albuminuria. The papillæ were paler than normal, but the retinal vessels presented no striking abnormality. R. V. = $\frac{6}{18}$; L. V. = movement of hand; refraction = E. The diagnosis was atrophy of both optic nerves.—*Klinische Monatsblätter*, May, 1883.

HEMORRHAGE AFTER ENUCLEATION.

Dr. Spaulding, of Portland, reports a case in which, after using, in vain, pressure and hot water, he succeeded in checking the hemorrhage by ligation of two arteries in the orbit. In the discussion in this case Prout said that in one instance he had controlled the flow by digital compression. Knapp referred to the necessity in enucleation of keeping close to the sclerotic. When the optic nerve is to be cut, it is a good plan to press the speculum into the socket: the eyeball is thus forced forward, and the nerve may more easily be divided.—*Amer. Ophth. Society*, 1883.

HYDROCEPHALUS WITH OPTIC NERVE ATROPHY, WITH CONTINUOUS FLOW OF WATERY FLUID FROM THE NOSE.

Professor Leber reports the following case. Patient was a girl, æt. 15½, hydrocephalic from birth. Six months ago, marked disturbance of sight developed, followed by frequent attacks of giddiness, later by two pronounced epileptic attacks. Atrophy of the optic disks, result of papillitis, was observed. Epileptic attacks recurred every six or eight weeks. Five days later, a continuous dropping of a watery fluid was observed from the nose. It varied in amount, reaching on one occasion in six hours 76 cub. cm. The epileptic attacks became very infrequent; headache and vertigo ceased apparently by reason of this flow. The sight did not improve. This fluid seems to have been cerebral. A few cases of the kind are on record.—*Arch. f. Ophthalm.*, 1883.

BRAIN-ABSCESS, WITH CHOKED DISK ON EACH SIDE.

Five weeks after the patient began to complain of cerebral symptoms, the result

of ophthalmoscopic examination was simply suggestive of a possibly commencing neuritis. Two weeks later, the cerebral symptoms having become more pronounced, a typical choked disk on each side was discovered. Post-mortem revealed two small abscesses involving left corpus striatum and a part of the thalamus opticus, also suppurative basilar meningitis. The case seems to have been one of brain-abscess, followed by basilar meningitis, perineuritis, and neuritis optici.—*Arch. für Ophthalmol.*, 1883.

IODOFORM IN CORNEAL AND CONJUNCTIVAL DISEASES.

Vossius gives the following results of considerable experience with iodoform. In a case of gonorrhœal ophthalmia it increased the discharge and swelling; one cornea, which previously was involved, was made worse, and the other, which had been intact, likewise became affected. Only one application was made, when a change of treatment was necessary. In blennorrhœa neonatorum it has no special value. In trachoma it sometimes seemed to do good, but oftener not: upon the granulations it did not act well, but sometimes when acute increase of the pannus would occur the iodoform seemed to relieve. Nor did it prove of value in phlyctenular conjunctivitis, pannus scrofulosis, parenchymatous keratitis. On the other hand, remarkably good results were attained in the treatment of corneal ulcer. Ninety corneal ulcers form the material upon which this statement is based. Especially in the *ulcus corneæ serpens* was the value of the remedy manifest. Thirty-six cases of this kind were treated: in seventeen of these severe dacrycystitis existed; in one old granulation with profuse purulent secretion. In three cases, Saemisch's operation was performed: in two of these, in spite of this and the iodoform treatment, the whole cornea became involved. In thirty-two of the cases surprisingly favorable results were attained by the iodoform alone. The iodoform was used in powder or in the form of salve. It seemed to produce an anodyne effect, relieving the violent ciliary pain and irritable condition of the eye. [An important practical matter seems to find illustration in this experience,—viz., that the treatment of local infection with septic material must vary with the nature of the infecting germ. Thus, certain septic forms of conjunctivitis and keratitis are very much helped by the

application of heat. The form of corneal ulcer above referred to, where the infection very often comes from the lachrymal sac, is certainly not very susceptible to the action of heat, but seems to require a substance which has a different therapeutic action. H.]—*Arch. f. Ophthalm.*, 1883.

CORNEAL GANGRENE PRODUCED BY INANITION.

Thalberg records some observations in corneal gangrene. Most of the cases were sucklings. The cause seemed to be malnutrition of the infant, or an impoverished condition of system in the mother, the result of prolonged fasting. The symptoms observed were sudden diffuse clouding of the cornea, generally preceded by xerosis of the conjunctiva, breaking down of the cornea, and sloughing. Sometimes, instead of diffuse clouding of the whole cornea, the opacity would be in the form of a white band which crossed the cornea. Sometimes two of these bands were present. Sometimes a catarrhal condition would occur, and then the case would closely resemble an ordinary blennorrhœa neonatorum with corneal necrosis. In the treatment very good results from the use of eserine in form of salve made with vaseline were obtained. By this is apparently meant that it was found useful after the necrosed tissue had been thrown off and a deep ulcer remained. It seems that the cases upon which these observations were made came under treatment generally at this stage of the disease.—*Archives of Ophthalmology*, June, 1883. [This morbid corneal process seems to be identical with that described by Graefe as corneal ulceration after infantile encephalitis, with the ophthalmia *Braziliana* of Gama de Lobo, and the corneal malacia described by Arlt. It is possible that malnutrition may be a secondary cause of the disease, but it is not likely that of itself it could produce corneal necrosis. A much more probable supposition is that these cases are caused by infection with micro-organisms. A case of this kind, which came under the reviewer's care some years since, was characterized by infiltration of the subconjunctival scleral conjunctiva, such as seen in diphtheritis. There was no false membrane. The patient died with profound typhoid symptoms. Post-mortem showed a healthy state of the intestines. The observation of Thalberg of the occurrence of a condition resembling blennorrhœa supports this view

somewhat, as this condition is probably due to a micro-organism. The value of the eserine in the treatment of this disease probably depended on its effect on the tension of the anterior chamber, as it seems generally to have been employed after the sloughing had taken place. The reviewer's experience teaches him that in certain forms of corneal infection, analogous to those referred to, eserine in the early stage will hasten the corneal disorder, and that an efficient method of treatment is the application of moist heat by cloths dipped in water as hot as can be well borne, for fifteen or twenty minutes at a time, the cloths being changed as fast as they cool. H.]

ARTIFICIAL RIPENING OF CATARACT.

Theobald reports two cases in which he made use of the method of Förster for hastening the cataractous process in partially opaque lenses. In one, the operation was imperfectly performed, and only slight change was produced. In the second, very rapid development of the cataract ensued. In each case, the operation was followed by iritis, with the formation of slight but persistent adhesions. In the discussion which followed, Drs. Gruening and Mittendorf had favorable experience to relate, Dr. Kipp had seen the lens become opaque, but not permanently so, Dr. Knapp had failed to produce any effect on the lens, Dr. Wadsworth's experience was similar to Knapp's. Dr. Noyes had performed the operation eight times. In one very marked iritis followed.—*Amer. Ophth. Society*, 1883. [The method of Förster consists in a sort of massage of the lens. An iridectomy is made, and then, while the anterior chamber is empty, the cornea is rubbed with the angle of a strabismus-hook. The instrument should be employed only in the area of the pupil and of the coloboma. The idea is so to disturb the clear portions of lens-structure in slowly-developing cataracts that the process may be hastened. The value of this procedure, if it accomplish all that is claimed, is apparent. Many patients to whom the loss of many months consumed in waiting for the completion of the morbid process means loss of position and support would be enabled in a comparatively brief period to undergo the operation. The production of the complete clouding of the lens seems to be undoubted. A pertinent question, however, suggests

itself: Is the clouding of the lens-tissue thus produced practically the same as that produced independently by the morbid process? Would this cataractous substance, artificially produced, readily be expelled in the extraction, or would there be considerable danger of cortical substance remaining behind? Then there is the risk of iritis, which seems to be considerable. The method doubtless will be further employed, and practical experience decide its status as a remedial measure. H.]

VASELINE SALVES.

Dr. Seely, of Cincinnati, was perhaps the first one to call attention to vaseline as an excipient in the preparation of the yellow ointment, so valuable in phlyctenular disease. Dr. Theobald, of Baltimore, uses as a basis for ointments for the eye a cerate composed of one part of yellow wax and four of vaseline.—*Amer. Ophth. Society*, 1883.

ELECTRICAL TREATMENT OF INSOMNIA.

BY WILLIAM R. D. BLACKWOOD, M.D.,

Electrician and Neurologist, Presbyterian Hospital; Physician to St. Mary's Hospital.

INSOMNIA presents itself as a factor in many diseases, but more particularly in those of the nervous system. In the earlier stages of insanity insomnia is very frequently met with, and the difficulty in overcoming the condition is very annoying to the physician; in fact, he is usually more troubled about it than the patient is, for, once mental aberration sets in, nothing is more likely to precipitate actual insanity than persistent wakefulness. In many fevers, also, loss of sleep is a prominent symptom and a distressing one, for in certain cases neither opiates, bromides, nor chloral are well tolerated, or, in fact, admissible. I know from personal experience, both in hospital and private practice, that not only injury during the acute stage, but also unnecessarily-delayed convalescence has resulted from incautious administration of drugs to procure sleep, in several types of fever. It is true that we have at our command other methods of tranquillizing a restless patient than drug-soporifics, but none have ever met the designed end with myself so well as electricity.

In relieving *pain* of many kinds, galvanic currents are invaluable, as is well known to any practitioner, and although

the evening restlessness of persons ill with depressing fevers may not be due to actual pain, its results are the same in the end, and the tossing to and fro is just as wearying as though it were accompanied by acute suffering. Electricity applied by the "general" method, as described, will, in the majority of such instances, act like a charm.

My usual plan is to apply *mild* faradic currents with one rheophore over the solar plexus, the other being held by its uninsulated portion in the same hand (the left) of the operator. The whole person of the patient, beginning with the head, is then gently stroked by the right hand of the manipulator, who thus can readily estimate the current strength; and it is better not to wet the hand used. The *sponges*, of course, must be well moistened. Care is taken to avoid painful points, as the brow, lower jaw, and sterno-cleido-mastoid, in the head and neck, but elsewhere the caution is less necessary. The most grateful effects are produced when brushing over the back and the limbs, the sufferer very frequently falling asleep whilst these parts are being attended to. Besides being able to judge the strength and regulate the quantity by increasing or decreasing the pressure of the hand, many of the good effects of massage in soothing the patient are thus obtained: in fact, I have more than once been asked, is not the whole good effect referrible to the simple and grateful friction? That it is not, may be easily determined by experiment, for although sleep may be induced by massage in some persons, it cannot be in others under precisely similar conditions, yet, if electricity be combined with the manipulation, failure will very seldom occur. In some instances where faradic currents would not act I have succeeded by substituting *galvanism*. The application is here made with some modification. First of all the penetrating and diffusing power of the constant current must be considered, and hence all applications to or near the brain are to be made guardedly. Anæmia or congestion at will of the brain is readily produced by galvanism, and although we in a measure desire to obtain the former condition, it is essential not to overdo it. From five to eight cells, therefore, of any battery of the Leclanche, the Law, or the gravity type, will suffice, and the frontal region is better avoided. With one rheo-

phore on the solar plexus (the negative) the anode is applied through the operator, as in faradization, to the vertex and down the neck, on either side (or both at once), thus influencing by the so-termed *central* galvanization the whole sympathetic nervous system, and without necessarily going over the whole body the desired effect is produced. There is no objection, however, to manipulating the other regions, and where much muscular soreness exists decided benefit is thus obtainable.

Except in hospital practice, it will be found inconvenient to employ galvanism, from the difficulty in transporting a good battery, the small zinc-carbon portable concerns being so unreliable. The physician, therefore, should try faithfully induction currents, prolonging the applications to a half-hour or more before giving up or resorting to galvanism. Do not make the very common mistake of substituting powerful for prolonged currents. It is *quantity* and not *intensity* which is required, and so far from attaining the object by an erroneous plan we only render our case less comfortable and defeat the object sought. So soon as muscular contraction is produced, the current is too strong: weaken it. If the patient complains of cramp, tingling, or numbness (pins and needles), he is getting too much: press more gently with the hand, or weaken the coil by its switch- or draw-tube. A current which will produce the crackling of dry cuticle is enough, and if the patient has a moist skin then give only so much as is barely perceptible to yourself: that will be enough. It may seem a waste of time and paper to write of this matter, but as all practical physicians grow older they learn to notice trifles, to depend less upon drugs, and to study every comfort of the sick. In protracted illness the nightly morphia, Dover's powder, or hypodermic becomes intolerable, and any method which may possibly supplant these is of value. Time and again I have had convalescents to thank me gratefully for the change, made, too, at times when from semi-delirium or other condition it was supposed that the patients would not notice such points, but which they remembered when able through returning strength to speak of them.

The skill requisite in electrical treatment of insomnia is very little; the time spent is not a drawback, but, if it is, the nurse,

mother, or other member of the family can take the doctor's place after a little instruction, and every general practitioner should possess a faradic instrument at least, for it comes into play so often nowadays as to be indispensable. Not long ago a professional friend who had been induced to try the method under consideration in a fever case, but who thought the battery a bad investment because so seldom needed, changed his opinion when in a case of an accidental overdose of morphia the person's life was saved by electricity. He owned up that a machine which would either make a wakeful patient sleep or wake a patient comatose from opium *was* worth possessing. Electricity is working its way rapidly into the ordinary needs of the day, and it is a good servant of the physician under intelligent control.

246 NORTH TWENTIETH STREET.

AN ACID SOLUTION OF THE HYPOPHOSPHITES.

BY GEORGE S. GERHARD, M.D.

MR. HAYES, of the St. George Pharmacy, has very successfully prepared, at my suggestion, a solution of the hypophosphites, without syrup, by dissolving the salts in water acidulated with hyposulphurous acid. The addition of a definite amount of this acid prevents the precipitation of at least two of the salts (iron and manganese), which in the syrups is accomplished by the protective power of the sugar.

The objection to the syrups is their excessive sweetness, and their liability to cause indigestion. The present solution, the formula of which I give below, is clear, slightly fluorescent, and pleasantly acid. It is a valuable tonic and stimulant, and is borne by the most sensitive stomach.

Calcii hypophosphit.,

A NOTE ON THE TREATMENT OF MALIGNANT CARBUNCLE AND BUBO.

BY M. L. NARDYZ, M.D.,
Philadelphia.

THE carbuncle, malignant bubo, and phagedæna are all local inflammatory processes, more or less dependent upon constitutional cachexia. Various causes operating upon the system so as to lower its vitality may be generally discovered by careful examination: in the former, senile enfeeblement, infirmity, and chronic debility from disease, or a condition of habitual repletion and irregularity of circulation, and connected with every species of excess; in the latter, there is the action of specific animal or mineral poison. In such conditions of the system these formidable local manifestations are sometimes developed upon the slightest local irritation. Thus, a furuncle of a young and healthy individual would be a carbuncle in one of an unhealthy character. The bubo of plague and that produced by the flesh of diseased animals is symptomatic of the poison which pervades the system, and the frightful cases of phagedæna which we sometimes witness in hospital practice are in most cases not to be explained by reference to the character or amount of the injury, mechanically considered, and result, therefore, from the operation of some powerfully-depressing cause upon the *vis vite* of the individual.

Of the same description, doubtless, in this respect is the horrible disease termed hospital gangrene and malignant ulcer, of which, however, we know little or nothing from personal observation.

I do not mean by these remarks to underrate the value of local treatment in such cases; it is most essential to facilitate nature's operations; but I mean to convey the idea that the local malady is symptomatic, whether commencing spontaneously or in consequence of lesion, and that calming and supporting the constitutional action is the efficient method of treating such diseases, whether that be done by local or general treatment, or by both. And there can be no occasion to illustrate the fact that surgical local treatment, as the division of structure, the renewal of the surface, is in many cases most influential in accomplishing this great purpose.

The practical objects to be effected, if possible, in carbuncle and phagedæna, are

the arrest of the gangrenous inflammation and the establishment of a free suppuration from the line of separation between life and death. Whenever this can be obtained there is reason to anticipate a favorable issue; and when it fails, and dryness is the condition of the sore, the contrary is to be looked for. A dry carbuncle is invariably fatal, in my experience.

NOTES OF HOSPITAL PRACTICE.

UNIVERSITY HOSPITAL.

CLINIC OF JOHN ASHHURST, JR., M.D., PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF PENNSYLVANIA.

Reported by LOUIS J. LAUTENBACH, M.D.

CLUB-FOOT TREATED WITHOUT TENOTOMY, BY KNEADING OF MUSCLES AND SUPPORT.

THIS boy has a deformity of the foot: it is one of a group of cases known as club-foot. The inner side of the foot is somewhat flattened, and the foot tends to turn out; if the deformity increases it will probably become a case of calcaneo-valgus. The left leg is the one affected most noticeably, but in neither does there appear to be much loss of power. Besides this defect in the ankle there is a tendency to knock-knee, this being, as it were, a continuation of the same process of eversion; it is, however, not sufficiently far advanced to be of much importance.

Coming now to the treatment, there is here no question of tenotomy, since there is no contraction, at least not such as cannot be overcome by simple mechanical measures; there is no spasm, there is simply a weakness of the muscles and ligaments; and as a result of their want of tone we have the present condition. We must here apply some mechanical support to prevent increase of the deformity, while we endeavor to improve the tone of the muscles by appropriate means.

We cannot, in many of these cases which depend upon infantile paralysis, cure our patients in the sense of restoring motion which is lost, but we can often do considerable good by preventing the deformity getting worse.

In the first place, we will use systematic frictions and kneading to the limbs, to keep the muscles and skin in good condition, and we will supplement this by the use of galvanism.

Our mechanical treatment will consist

in the application of a small pad on each side of the ankle in connection with light iron rods going up from the sole of the shoe, and provided also with a pad on each side of the knee. This is all the treatment that can be usefully applied. It may be possible that a similar apparatus will at some future time have to be applied to the right leg to prevent the development of a similar condition there.

We have here another orthopædic case, one of club-foot, which you will recognize at once as a case of calcaneo-valgus. The foot is everted and the heel is drawn down. Here there is not, as yet, any decided fixation; the case is still susceptible of treatment by the use of apparatus and friction, without tenotomy. If, however, the case goes much longer without treatment, the tendons will become contracted and the foot fixed, and it will then be necessary to divide the tendons of the long and short peroneal muscles, and perhaps those of the extensors of the toes, and even that of the anterior tibial. It would not be necessary to divide the tendo Achillis here, as the heel is not retracted. We find here a curious condition of what is called luxation of a tendon: one of the peroneal tendons is in front of the external malleolus instead of behind it, but slips quite easily into its proper position when pressed upon.

POLYPUS OF THE NASAL SEPTUM—REMOVAL.

Our next case is one of tumor of the nose. It does not look like the ordinary simple nasal polypus, which is the most common form of nasal tumor. The tumor here is attached to the septum, and has a very vascular appearance. Nasal polypi are usually attached to the turbinated bones; they may be attached at any point, but they occur only very rarely on the septum. Polypi are usually of a more or less yellow appearance, and have not the deep vascular tint which this has.

I will try to remove the tumor with the ordinary polypus forceps, and, if I do not succeed with this, will use a small gouge, which is a very convenient instrument for operations within the nose.

Before attempting to remove a nasal polypus you should always satisfy yourself of the exact point of attachment. This tumor is attached to the septum by means of a neck which is rather broad. Here the tumor is clasped comparatively easily

by the forceps, and on twisting the instrument the mass of the tumor comes out, its deeper parts looking more like the ordinary nasal polypus than the part which was seen in the nostril. Examining the nasal cavity further, as usually there are several polypi present, we find that we have no more tumors to take out.

Besides the ordinary nasal polypus, which is usually a myxoma, though sometimes an adenoma, there is occasionally a firmer growth met with in the nose, which is called a fibrous polypus. This is a comparatively rare tumor, and in some cases which I have seen has been of a sarcomatous nature. The tumor in this case is firmer than the ordinary polypus, and probably contains glandular tissue, so that it might be called a polypoid adenoma.

WHITE SWELLING OF THE KNEE.

This boy represents a class of joint-diseases of which we see a great many. He has been under treatment a long while. It is a case of disease of the knee-joint known as gelatinous arthritis, or white swelling. It is a case which may some day require more active measures than we have as yet adopted. Many of these cases, if not carefully treated, eventually require either excision of the knee-joint or amputation above the knee. Excision does not do well in very young children. The operation should not be done, if it can possibly be avoided, in children under nine or ten years of age, as the results usually are not very satisfactory: sometimes you fail to get bony union altogether, and if you do get bony union there is apt to be considerable deformity, owing to the restlessness of the patient.

Another risk which follows the operation of excision in young children is that of recurring deformity. Of this I have seen two cases in my own practice. One case of recurring deformity after excision of the knee was in a little girl six or seven years old, who went out from the hospital with a straight knee which appeared quite firm, but she came back some months afterwards with considerable deformity. In that case I used a posterior splint and an elastic bandage, which restored the limb to its proper position. The second case was in a girl eight or nine years old, who also went out from the hospital with a limb straight and apparently firm. I lost sight of her for about ten years, when

she came back with the limb very much contracted, the leg making an angle of about ninety degrees with the thigh. Bony union had occurred in this abnormal position, and it was found necessary to perform a re-excision. These reasons make me hesitate about recommending an operation in young children if it can be avoided.

If, in a case of this kind, in a child, you find much deformity, you may divide the hamstring-tendons subcutaneously, then straighten the limb as much as possible, and use the plaster-of-Paris bandage to keep it straight. This will put the part at rest, and at least prevent the disease from getting worse.

In using the plaster bandage, you should first pad the knee well with cotton, and then carry a flannel bandage from just above the ankle to more than half-way up the thigh, in order to fix the bones above and below the joint and thus to prevent motion of the articulation. Now on top of this you apply a bandage of crinoline or mosquito-netting having plaster of Paris within its meshes. Before applying this it is soaked in water, and then the superabundant water pressed out. The fixing-power of the plaster may be supplemented by adding strips of pasteboard or wood, or, better still, of metal,—especially of perforated zinc or tin,—so as to prevent their slipping. Over these strips put a second plaster bandage, and then keep the limb straight until the plaster has set.

RACHITIC CHILD.

This child has just been brought to us for the determination of the question whether any mechanical apparatus can be of use, and, if so, of what kind. The child cannot hold its back straight. There is a deformity of the chest; the breathing at times is attended with great oppression. The child is suffering with rachitis. The contour of the breast is very characteristic: there is a drawing in of the lower part of the breast, and a curvature of the back which is distinct from other forms of curvature. This is not as marked when the child is standing up as it is when he is sitting down, as while standing he puts the muscles in action. He has an antero-posterior curvature which is very different from the antero-posterior curvature of Pott's disease, or caries of the spine. Here we have a general curvature,—an exaggeration of the natural curve. In young children the ordinary S shape of the spine

is not observable, this coming on later in life from muscular action. In children the whole back is normally convex, but not as much so as here. There is also here a tendency to lateral curvature; this is simply from weakness. The child braces itself, when sitting, by supporting itself on its palms. The spine is convex to the right in the lumbar region, and convex to the left in the thoracic region. The lateral curvature is due to the rotation of the vertebræ on themselves, from the weakness of their ligaments. The other symptoms of rachitis are not as well marked here as we sometimes see them. The epiphyses of the long bones are often enlarged, giving a double-jointed appearance which is not well marked here. We have here, however, a tendency to "beading" of the ribs, which is especially well marked at the junction of the ribs with the cartilage. Sometimes there is a complete row of beads on both sides. This, when present, has been termed the rachitic rosary. The teeth in these cases are nearly always deformed.

The most important remedy in these cases is cod-liver oil, which may be given freely. This is of more value than all the braces and splints that could possibly be used. English surgeons use a great deal in these cases the *hydrargyrum cum cretâ*, or gray powder, and claim for it great value. Some preparation of mercury may be at times necessary, and if it becomes so you may use small doses either of gray powder or of blue mass; but the continued use of remedies of this kind is not to be recommended. In addition to the cod-liver oil the child should have good food and exercise in the open air, but especially passive exercise. In addition, a light spinal support should be applied, with a view simply of preventing the occurrence of deformity while the general condition is being improved. The important measures here consist in general constitutional and hygienic treatment; the use of apparatus is a secondary matter. In some cases, however, where there is a tendency to bow-legs, it is very important to use apparatus at an early period.

FOREIGN BODY IN TRACHEA—REMOVAL BY TRACHEOTOMY—DIFFICULTY OF BREATHING WITHOUT THE TUBE.

This young child, a boy, was admitted in a condition of extreme danger from the presence of a foreign body in the trachea. It was a case which required prompt and

immediate treatment, which consisted in opening the trachea, when two foreign bodies—portions of a grain of corn—were ejected. Since then the child has had a slight attack of bronchitis, but has done perfectly well, except that he has not been able to dispense with the tube.

This might be owing to the presence of a foreign body in the larynx; but I think that it is due to the fact that when the tube is removed the tissues of the neck are sucked in, closing the trachea as by a valve. If by laryngoscopic examination we should be able to determine the presence of a foreign body in the larynx, it should be, of course, removed; but if a laryngoscopic examination cannot be satisfactorily made, we will etherize the child and remove the tube, watching closely in order to discover whether there is any real mechanical obstruction or whether the difficulty is due to spasmodic action. Perhaps when the child comes from under the influence of ether he will not notice that the tube is gone, and we may then be able to dispense with it. This tube here is the ordinary fenestrated tube. Immediately after the operation we used a silver tube, not fenestrated; but after this had been worn a little while the fenestrated tube was substituted for it, so as to allow the passage of air through the larynx.

TRANSLATIONS.

THE MODERN RADICAL OPERATION FOR HERNIA.—Dr. H. Leisrink has recently attempted the collection and analysis of all the published radical operations for hernia, his statistics covering 390 cases, many of which were personally communicated to him and are otherwise unpublished. His cases are divided into two groups, those in which strangulation had not occurred, and those in which the operation was undertaken for its relief.

In the first group he reports 169 cases of inguinal hernia (153 in males and 8 in females), 25 femoral herniæ (2 in males and 23 in females), 8 navel and abdominal herniæ (4 males and 4 females), in all 202 (79 per cent. males, 17 per cent. females). In the second group, where strangulation had occurred, there are 103 cases of inguinal hernia (74 males and 26 females), 77 femoral herniæ (11 males and 66 females), 7

navel and abdominal herniæ (3 males and 4 females), and 1 case of obturator hernia; in all 188 (46 $\frac{2}{3}$ per cent. males, 51 $\frac{8}{9}$ per cent. females). Operations for fæcal fistula and resection of the intestine are not included in these statistics.

In the first group the operation was successful in 184 cases (91 per cent.), 15 died, and of these sepsis was the cause of death in 9 (4 $\frac{1}{3}$ per cent.).

Inasmuch as the author reckons that at least twenty-one days are necessary in herniotomy for healing by first intention, it follows from his tables that in 44 cases (21 $\frac{3}{4}$ per cent.) complete asepsis of the wound was not obtained. In the great majority of his cases the time for which the patients were under observation after the operation was far too short to exclude a return of the disease, while in 20 per cent. of the cases a return was reported; but in many of these the condition of the patients after the operation was much better than before. The mortality, however, in this operation is so large that the author believes that in cases in which reduction can be maintained by trusses, as well as in children and old persons, the operation is not advisable.

In the second group, where the operation was performed for strangulation, cure resulted in 155 cases (82 $\frac{1}{2}$ per cent.), while death occurred in 33 cases (17 $\frac{2}{3}$ per cent.), and of these in 6 instances (3 $\frac{1}{6}$ per cent.) from septicæmia.

The duration of the strangulation, as might be expected, was of great influence on the result: thus, in 23 cases in which the operation was performed within fifty hours after the onset of strangulation, only 2 died (8 $\frac{2}{3}$ per cent.), while in cases of longer duration 7 (33 $\frac{1}{3}$ per cent.) died.

The hernia returned in only 8 $\frac{1}{6}$ per cent. of the cases. The indications, therefore, are, when there are no special reasons against opening the peritoneal cavity, to perform the radical operation immediately after the relief of the strangulation.

As regards method, the author advises the slitting of the canal, extirpation of the hernial sac, and occlusion of the ring by stitching, while he is opposed to Czerny's method of ligature.—*Centralblatt für Chirurgie*, July 28, 1883.

A FÆTUS REMAINING FIFTY-SIX YEARS WITHOUT CHANGE IN A CASE OF EXTRA-UTERINE PREGNANCY.—M. Sappey, in a

very interesting communication to the Academy of Sciences (*Courrier Médical*), reported a case that is probably without parallel in medical annals. A woman at 28 years of age became pregnant, but was not delivered. She carried an abdominal enlargement until she died at eighty-four years. At the autopsy a large tumor was found outside of the uterus, connected with the right Fallopian tube. The wall of the cyst was tough, and its surface calcareous and nodular. After removal the cyst was divided with a saw, and, very much to the surprise of the spectators, a fœtus of about seven months' development was found in its interior. During its long captivity it had been perfectly preserved, not having undergone any alteration. "It was in the ordinary attitude, the limbs flexed upon the trunk, the head inclined on the thorax. The pupillary membranes were completely developed, and fixed the age at from six to seven months. The cutaneous envelope, the superficial organs, as well as the viscera in the large cavities of the body, all the muscles and soft parts, retained their consistence, their suppleness, and their normal color. The fœtus, in short, presented all the features of an infant which had just gone to sleep." This case alone upsets the ordinary views with regard to the calcification and desiccation of the fœtus being necessary for the preservation of a fœtus retained in the abdominal cavity. According to Sappey, "infants which after their death are retained indefinitely in the abdomen of the mother owe their preservation to the physical conditions of their imprisonment, which give them a refuge from atmospheric germs."—*Gazette Médicale de Nantes*.

NEW THEORY OF THE ORIGIN OF BACILLI.—Bouchardat, at the last meeting of the Paris Academy of Medicine, denied the specificity and contagion of the so-called tubercle-bacillus. He attributes these organisms to a fault of nutrition, as the result of which leucocytes acquire the power of transforming themselves into pathogenic bacilli.—*Berliner Klin. Wochenschrift*.

THE NEW ANTIPYRETICS.—From some experiments made by Silvestrini, in Parma, he concludes that he is warranted in expressing some doubts as to the asserted indisputable antipyretic powers of kairin and resorcin.—*La France Médicale*, No. 43.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, NOVEMBER 3, 1883.

EDITORIAL.

THE NEED OF GOOD NURSES.

AS the art of medicine becomes more highly cultivated, the importance of the care of the sick, and of the hygiene of the sick-room, is gradually assuming a higher relative position in the minds of the profession. It is seen that the most successful practitioner is not necessarily the most scientific pharmacologist, but he who knows best how to order all things for the good of his patient; the most successful surgeon, not necessarily the most expert operator, but he who looks carefully after his patient both before and after the operation. In order that a physician may be well seconded in his efforts to keep up the hygiene of the sick-room to the proper standpoint, he must have an able and intelligent *locum tenens* in the nurse, who will not only see his instructions faithfully carried out, but will have sufficient knowledge and skill to anticipate and prevent transgressions which the physician may not have anticipated or could not foresee, yet which might otherwise be followed by serious if not fatal consequences. How many illustrations might be given where indiscretion or disobedience on the part of the patient or his care-taker has been followed by irreparable injury! The medical attendant in a dangerous case feels his responsibility, or at least his anxiety, immensely reduced when he knows that he has an expert and trustworthy assistant remaining near the patient, who can be relied upon to do his bidding in his absence. Prof. Gross, in a recent communication, sums up the character of the ideal nurse as follows:*

"The chief qualities of a nurse are perfect health, refinement, neatness of person, correct habits, kindness of heart,

patience, power of endurance, a good temper, a discreet tongue, good judgment, and alertness of mind. Such a combination of qualities is rare, but where it is present, and has been improved by a rigid course of training, it fulfils the very highest requirements of the sick-room. Endowed with such an array of gifts, a nurse is capable of doing an amount of good in combating disease in a degree hardly inferior to that of the medical attendant himself. She diffuses light and courage and sympathy in all her acts and movements, and thus robs disease of half its fears and pangs."

It needs but little reflection to show the value to the practising physician of a supply of such trained and trustworthy nurses drawn from the better class of society. It is therefore desirable that this vocation should be elevated to a higher position in public and professional esteem, in order that persons of refinement and good breeding may be encouraged to adopt it as a means not only of earning a respectable living, but also of rendering the most valuable service in their power to humanity. Among persons naturally devoid of these necessary qualities of tact and refinement, a little training, unfortunately, seems only to render them self-sufficient, obtrusive, and generally offensive, glossing over their native inefficiency with the merest presumption of knowledge. The sick can be spared from the officiousness of such care-takers only by the determined attitude of the physician.

Prof. Gross recommended, in a well-considered report upon the subject, made to the American Medical Association in 1869, that district schools of nursing should be established under the auspices of the County Medical Societies, the members of which might deliver lectures upon the science and art of nursing, including the elements of hygiene and other necessary information. At the last meetings both of the American Medical Association and of the Pennsylvania State Medical Society, he again called attention to this important subject, and offered resolutions, which were unanimously adopted, recommending the establishment in every county town in our States and Territories of schools or societies for the efficient training of nurses; male and female, the members of the

* Medical News.

County Societies giving instruction either gratuitously or at such reasonable rates as should not debar the poor from availing themselves of their benefit.

In the words of the author of the resolutions, "trained nursing is rapidly assuming the form of a dignified profession. It is no longer a menial occupation, but an art and a science." So much importance does he attach to the plan he has proposed, that he declares he shall feel, if it succeeds, as if he had accomplished the greatest work of his life.

There has been, within a few years, a great revival of public interest on this subject in Europe, chiefly owing to the influence and efforts of Prof. Esmarch in Germany, the Princess Christian in England, the Society of the Red Cross, and the St. John's Ambulance Association: numerous Samaritan Schools have been organized, and courses of lectures have been delivered. It is true that these have had in view principally the rendering of first aid to the injured, and the treatment of emergencies; but the result has been to direct public attention pointedly to the care of the sick and injured. A society of this kind in New York has been engaged for more than a year in establishing branch societies throughout that State. Public lectures upon Emergencies, under the auspices of the Philadelphia Society for Organizing Charity, have been delivered, with great benefit to the public, in this city, of which the nurse-training schools have already a well-earned reputation. The present time seems a favorable one for extending these advantages to other places throughout our State and country. There cannot be too many good nurses; indeed, it is doubtful if the supply will be able to keep up with the demand when the community once learns to appreciate fully the value of the services of skilled attendants, whose judicious aid is always welcomed by the physician.

THE CELEBRATION OF THE HARVARD CENTENNIAL AT BOSTON.

THROUGH the well-directed liberality of some of Boston's principal citizens, a fund of three hundred thousand dollars was contributed for the purpose of providing a new building for the medical department of Harvard University. The gift was doubly welcome, being in recognition of the valuable services which this school had rendered to the community by its labors in the direction of higher medical education, and because the institution had outgrown the inefficient accommodations formerly provided for its purposes. The school having finished a century of usefulness, it was thought by its friends that the occasion could not be celebrated in a more fitting manner than by erecting a new Medical Hall, with lecture-rooms and laboratories fully equipped and adapted for the best methods of modern instruction.

The formal opening and dedication of this handsome building constituted part of the exercises of the celebration of the one-hundredth anniversary of the foundation of the medical school of Harvard University, held October 17, 1883. Cards of invitation were sent to distinguished members of the profession in other cities, a large number of whom were present, including Sir Lyon Playfair and Sir William MacCormac, of London, Dr. Osler, of Montreal, Dr. Mullin, of Hamilton, and Dr. Aiken, of Toronto, also many prominent American physicians.

The opening exercises were held at Huntington Hall, in the Massachusetts Institute of Technology, beginning at eleven o'clock A.M. by a brief address from President Eliot, who introduced Dr. Oliver Wendell Holmes, Emeritus Professor of Anatomy, the orator of the occasion. Dr. Holmes gave a short account of the early history of the medical school, followed by some personal reminiscences of his own college days, and of the distinguished men who had formed its Faculty at different

periods. He spoke of the progress made in the art of medicine within the last third of a century, and of the gradual growth of a knowledge of the true principles of medical science and of a healthier sentiment with regard to the relative value of drug-giving and hygiene. The address abounded in witty allusions, which were well relished by his audience, and his remarks were frequently interrupted by applause.

After the oration was ended, there was a presentation of a life-size painting of Dr. Holmes, in his professional gown, to the medical school, by Dr. Francis Minot in behalf of the donors, and of a marble bust of Henry J. Bigelow, by Hon. Samuel A. Green in behalf of the donors. They were accepted by President Eliot, who in the name of the University thanked the unnamed friends for these valuable mementos.

At this point in the proceedings Dr. J. Collins Warren, chairman of the Committee on Arrangements, invited the guests to repair to the new medical hall, on Boylston Street, near Exeter, where the remainder of the programme was carried out.

On entering the front door of the large and ornate building which hereafter is to be known as the Hall of the Medical Department of Harvard University, the visitors found themselves in a spacious vestibule surrounding the grand stair-way: upon these steps, about half-way up, the Faculty, with a few friends, formed a group, among which was the Rev. Andrew P. Peabody, D.D., who offered a brief prayer. President Charles W. Eliot, on behalf of the corporation, then, in a few words, formally dedicated the building to the purposes of medical instruction. Addresses were also made by Henry Lee, Esq., in behalf of the contributors, and Prof. Henry W. Williams, in behalf of the medical Faculty. A general reception was then held by the medical Faculty, and the subscribers to the building-fund, with the invited guests, partook of a fine collation. The Warren

collection and other valuable specimens in the museum, and the various laboratories, were thrown open for inspection.

The building is of fine brick, well lighted, well ventilated, and fire-proof in construction: it was described by our Boston correspondent in our last issue. It seems in every way well adapted for the purpose to which it has been dedicated. No extravagance of architecture mars its usefulness for teaching, nor, on the other hand, is there any evidence that ugliness has been mistaken for utility.

In the evening a reception to the invited guests was given by the Faculty at Young's Hotel.

The weather, the occasion, and the address of Dr. Holmes were alike inimitable. Of Harvard, for the sake of the practical solution she is rendering of the problem of higher medical education,—and of all enterprises of similar character, wherever in this broad land they may be located,—we can heartily say, *Esto perpetua!*

CLINICAL TEACHING AT THE UNIVERSITY OF PENNSYLVANIA.

IN the notice of medical teaching in Philadelphia, contained in our last issue, the list of the Faculty of the University of Pennsylvania is incomplete: it should have contained the names of William F. Norris, M.D., Clinical Professor of Diseases of the Eye; George Strawbridge, M.D., Clinical Professor of Diseases of the Ear; and Louis A. Duhring, M.D., Clinical Professor of Diseases of the Skin, all of whom have been teaching at the University for many years.

Prof. Horatio C. Wood, M.D., is Clinical Professor of Nervous Diseases, as well as Professor of Materia Medica, Pharmacy, and General Therapeutics. This clinical course, with practical bedside instruction, likewise, in Medicine, Surgery, and Gynecology, is made a special feature of the third term of lectures.

NOTES FROM SPECIAL CORRESPONDENTS.

CINCINNATI.

AS the schools have settled down to their winter's work, it is proper to devote this communication to a consideration of their methods. There are three regular medical colleges in this city. The Medical College of Ohio is the oldest, and is the only one at present a member of the American Medical College Association. The number of students in attendance this year is not quite three hundred, but the students in this, as is also the case with the other colleges, are not all in yet. There has been an advance in the requirements for graduation, so that now, in addition to the Association requirements, all students are required to attend hospital clinics each year of their attendance at college, and each student is required to dissect each of the three divisions of the cadaver.

This college pays special attention to its out-door clinical department. There are six clinics in daily operation, in which an average of over two hundred patients daily are treated. The students are here permitted to handle the patients, to make physical examinations, and to diagnose the cases. Two or three students find work as assistants in each of the clinics, thus bringing them into more intimate relations with the work. The practical courses in chemistry, histology, and pathology are well attended, each year increasing the number of students taking these extra branches. Then there are private quizzes, classes in physical diagnosis, in ophthalmology, in laryngoscopy, in operative surgery, and obstetrics. During the year several cases of obstetrics are brought before the class in the large amphitheatre for practical demonstration of the process of parturition. This college has complete control of the Good Samaritan Hospital.

The Ohio Medical College was founded in 1819, making it one of the oldest colleges in the West.

The Miami Medical College ranks second in point of numbers,—it having not quite one hundred students in attendance. The inducements offered here are very similar to those at the Ohio. The Faculty, not having any hospital of their own, pay especial attention to the large City Hospital. Their out-door clinics have been recently extensively enlarged and a set of intelligent young men placed in charge. Their practical departments consist of anatomy, chemistry, and histology: at the head of each is placed an active, qualified young man who carries much enthusiasm with him into his special department.

The Cincinnati College of Medicine and Surgery has had rather a variable career. It is the second oldest college in the city, and until recently has been conducted as a first-

class institution, but its chief value now seems to be as an advertising medium for the Faculty. It has not a half-hundred students in attendance, and, as the tuition is only thirty-five dollars (the tuition in the other schools is seventy-five dollars), it cannot in any sense adequately pay money to its Faculty. Some of the most prominent members of the Faculty reside outside of the city in neighboring towns and villages, and for them it is quite a big thing to come into the city twice a week to lecture,—and it doubtless adds not a little to their local fame.

In addition to these three regular colleges, there are four irregular: two of these conduct lectures from five to eight months in the year, a third has lectures occasionally, and the fourth is simply a diploma-mill.

From all of these institutions, about two hundred graduates are poured out each year, about half of whom come from the Ohio Medical College.

If the hospital and clinical material were well utilized, two good colleges could be well supported; but I fear the multiplication of colleges comes from the selfish desire to be a "professor," instead of honest "doctor."

The Cincinnati Hospital ranks first in size. It contains five hundred and four beds, arranged in eighteen wards. The hospital is an imposing structure, architecturally speaking, and is built around a hollow square in a way to afford in each ward ventilation from the four points of the compass.

There is an amphitheatre at one end of the hospital, capable of seating three hundred students, where clinical lectures are delivered by the staff six mornings in the week for five months, while the colleges are in session. Students from any medical college in the city can attend these lectures by paying five dollars, which amount goes into the hospital library fund.

No bedside instruction is allowed in this institution, and, as a consequence, while our citizens pay eighty thousand dollars a year for a hospital, but little good, clinically speaking, accrues to the medical students of the city. Six resident physicians are chosen each year by competitive examination to serve for one year without salary. They are furnished lodging, washing, and board by the hospital, and are under the direction of the medical staff. They rotate in service, so that in the year they get four months in the medical wards, four months in the surgical, two months each in the obstetrical and ophthalmological. These six internes really get all of the clinical instruction which this great hospital affords. Two or three members of the staff have overstepped the rules and take small classes through the wards once or twice a week, but they do this only at the risk of having their official heads cut off. There is probably less clinical material utilized in this hospital, in proportion to the amount present, than in any

other large hospital in the civilized world. As a consequence, numbers of our students are driven abroad yearly to get what is denied them at home.

The Good Samaritan Hospital is under the charge of the Faculty of the Medical College of Ohio. It contains nearly two hundred beds, including the Marine's. The best and largest clinical amphitheatre of the city is in connection with this hospital, and only students of the Ohio Medical College are admitted. Bed-side instruction is also here a secondary matter, although it is better utilized than in the City Hospital. Many of the Faculty of the Ohio Medical College send their private operating cases here, so that the number of major operations here is about equal to the larger City Hospital. Three internes are selected from the graduating class of the Ohio Medical College each year to serve for one year in this hospital on nearly the same terms as the City Hospital internes.

The St. Mary's Hospital contains two hundred and fifty beds, and is not connected with any medical college. The staff is composed of eight distinguished medical gentlemen of the city, headed by Charles S. Muscroft, Sr. All of the nursing and inside attendance is done by the Sisters in charge, and Dr. Muscroft assures me that it is well done. The clinical material of this large hospital is not utilized at all in the way of the instruction of students.

There is also a Jewish Hospital in the city, containing about seventy-five beds, but it is not thrown open to the public in any way.

Thus it can be readily seen that while there must be an abundance of clinical material in the hospitals of Cincinnati, yet it is utilized in about the poorest possible manner. Tens of thousands of dollars are thus driven to Europe each year which could much more profitably be expended here, were things not as they are, but as they should be.

A. B. T.

CINCINNATI, October 15, 1883.

CORRESPONDENCE.

LONDON LETTER.

THE work of another session has commenced at the medical schools, which in London, at least, start with a reasonable number of subjects for dissection, in which there has been an unfortunate scarcity of recent years. But the parochial undertaker has been checkmated at last, and mock relatives are at a discount; and the corpses of our social failures are more useful after death than their owners were in life. Anatomy is going to have a full swing this year. The introductory addresses have been delivered at the different schools, and are scarcely of a very high order of interest. Still, such ad-

resses have a value, and an abstract of some of them may be of interest. At St. George's Hospital the address was given by W. H. Bennett (Assistant Surgeon), in which he considered "The Social Position of the Medical Profession." He compared it with that of the church, the army, and the law. With regard to the first two, he held they possessed attractions which medicine could never attain. He held the law to have more allurements. He quoted from a writer of high social standing, "This choice of a profession is not an easy matter, when, as a rule, the church, the army, the bar, and the diplomatic service are almost the only four professions open to a young fellow." Medicine is conspicuous by its absence. (How different it is on your side of the water, where the ranks of medicine contain scions from some of your best families!) He went on to say the law was patronized far more freely by society of a certain rank than was medicine. For this he thought there were two main reasons. The first was that a certain portion of our work was of a "menial" kind, and repulsive. Especially was this last connected with the early part of the educational career. The other was that a medical man was never free from the fetters of his business, and was constantly at the call of the public; while the recognition of medicine by the State was very small. Then, of course, the "political powerlessness of the profession" came in for recognition. He then discussed the position of consultants, and said, "For there could surely be nothing more lowering to the social standing of the profession than commercial competition between those who should be its leaders and those who formed its general working body." At King's College, Dr. Acland, F.R.S., insisted upon something more than "a wholly secular and materialistic education." For reasons which he need not then relate, the Medical Council had abstained from entering upon this stormy topic in its recommendations on general education; but, in his opinion, the importing religion into scientific teaching was fraught with danger both to religion and to precise knowledge." Certainly the introduction of a religious sisterhood into the working of King's College Hospital has been fraught with disaster, if that has anything to do with the question. At St. Mary's Hospital the address was delivered by that respected veteran of the profession, Dr. Handfield Jones, which was mainly of strictly local interest, relating to the school and its history and prospects. At the Middlesex Hospital, Mr. Pearce Gould referred to the recent Royal Commission as to the profession and the late Bill. He sat upon the corporations "which have degraded the profession and have deceived the public." (Those naughty corporations, which, amidst scorn and condemnation, live on, pretty much after the theory embodied in a North-country proverb,—viz., "The devil

gives long leases to those he is sure of"). He then pointed out how much had been done of late years as to the localization of disease and the local effects of disease, but warned his hearers not to be tempted to devote an undue amount of time and attention to these matters, to the exclusion of general pathology. At the London School of Medicine for Women Dr. Horatio Donkin selected as his topic "Popular and National Therapeutics,"—just about the last subject one would imagine to choose for the ladies. "To the treatment of symptoms as if they were diseases might, indeed, be referred almost all forms of quackery in medicine," he told the gentle sex. But how to treat softening tubercle, for instance, without "treating symptoms," as it is called, for the life of me I cannot tell. If one cannot wrestle with some of its constitutional effects, what can one do for the hapless patient? But, however, it is not my duty to be judicial. At Queen's College, Birmingham, the address was delivered by Bennett May, F.R.C.S., and at Owen's College, Manchester, by Professor Arthur Gamgee, F.R.S., who pointed out how Owen's College had been united to the Manchester School of Medicine. He then described the position in which they stood to the new Victoria University, an examining and degree-conferring institution. Prof. John Tweedy, at University College, pointed out with pride the roll of illustrious names from (my kinsman) John Elliotson downwards. He insisted they must be medical men first and University College men afterwards. He gave his hearers some sound practical advice about how to pursue their studies in the most profitable manner. At this point he insisted upon the importance of maintaining the health during the years of study. As to the practitioner, he quoted Guy of Chauliac: "A surgeon should be learned, expert, ingenious, and well-mannered; he should be bold when sure, cautious in danger, kind to patients, gracious to colleagues, modest in giving an opinion, chaste, sober, pitiful, and merciful, and not greedy of gain,"—which shows that old Guy knew very well what was desirable in a surgeon; and I trust a goodly proportion of Mr. Tweedy's audience will strive to live up to this high standard. By far the most original and interesting address was that delivered at the Leeds School of Medicine by T. Clifford Allbutt, M.A., M.D., F.R.S., the well-known physician of that town, on "Medical Study and Practice." He began by referring to the freedom attained on leaving school for a calling, which, he said, tempted to extravagance, which their professor of physiology would tell them was that waste of power which may be but a condition of new growth. "O young men, why will you buy your experience so dear, when we are crying wisdom in the streets for naught? Let us who have passed your day never have to look with sympathetic

sadness upon opportunities unseen, upon chances slipped away, upon time wasted and wasting you again, upon squandered wits and powers dissipated." Then as to the want of organization in the profession. "If organization is to mean the dictation of creed-mongers and the suppression of all intellectual variety, then I for one am content to be disorganized. If political power means the setting up of some medical semaphore in one or other House, who may consent to utter only our shibboleths and take from us his sole political color, then I for one am content to be politically powerless." He then spoke of the position of the "general practitioner." "Did the members of any other profession ever seek odium, and even rancorous enmity, by persistent efforts to cut down their own incomes in the interests of their clients? To speak plainly: enteric fever, for instance, was worth perhaps a steady hundred a year to many a town or country practice,—not counting the luck of epidemics. Now, hundreds of doctors—you know many of them yourselves—in human pity have striven to suppress this and other maladies, spoiling their own incomes, and earning, not the thanks, but even the curses of the public; offending not the poor, but the rich,—the landlords, the thriving farmers, the Poor-Law Guardians,—the class upon whom the rest of their shrunken practice must depend. Again, in the quiet heroism of daily life these same men and their brethren labor day and night for sick and suffering persons who can never repay them with money. Some walk in the squalid and hideous places of large towns, others among the poor widely scattered over moor and fell. I said to one of these, as I pointed to a vast mountain-side deep in snow, 'How do the poor fellows up there get aid in winter?' 'Oh, we have to go somehow,' he cheerily replied. 'And how are you ever paid for such labor?' 'Never,' he said. 'But there is no doctor for seven miles on that side, for five miles on that side, nor even for ten miles on the other; and if an old chap gets a strangulated hernia in the middle of the night up there, one is bound to go.' I silently took my first-class seat in an express-train homeward, with a check in my pocket, thinking, 'And these are the men who are called the "lower grade" of the profession, and who are not fit even to vote for their own Colleges of Physicians or Surgeons!'" Then he went on, "Such, then, is the body of men in which you are to be enrolled,—men who would not be human had they not faults also. Let me warn those of you now entering practice against some of these. Our worst fault is, I fear, that we are a somewhat touchy and jealous class. Our cousins at the bar set us a contrary example, to our shame. We work under conditions which tend to breed distrust. Unlike the bar, we do not play with our cards above the table. In our more intimate work

it is terribly easy for one doctor, by little intangible tricks, to elbow out or depreciate another. Then, for the same reason, the public often fail in loyalty and candor with us, and work mischief in their own little ways. Difficulties would often be avoided if we were not too often disposed to assume some property in our patients, and to think because they come to us at times they have no business at other times to consult some other man. It is not fair to put business of any kind into the hands of two men at once without a due understanding between them. But we must not go beyond this and say that a man has no right to consult whom he pleases and deny his right to be the judge of his own interests." As to calling of consultations, he said wisely, "I find it is the best men who seek consultations, and the less capable and those more ignorant of the world who shirk them. How clearly men who have been in practice realize this! but the young beginner does not see it." Then he urged them if they have any grievances among themselves never to write letters to professional brethren: "Charges are thus made without reserve; words easily used on paper which would have lingered on the lips, but which cannot be recalled; the favorable influence of man on man is lost, and a lifetime may hardly hold mischief, which in a personal interview would have gone piping down the wind. Medical etiquette is good behavior, and our rule the golden rule of doing as we would be done by,—of acting candidly and considerately towards ourselves and towards the public. Looking only to the happiness of our lives, what more fatal poison can you have in your cup than a chronic ill humor? What more irksome way than to meet your medical brother daily in the street with sulky look or neglect? An ill-bred fellow once told me it was the doctors' wives who kept their husbands so often at loggerheads,—a fellow whom I need not say that I have no hope of, and whom I only name to reprobate. As to your patient, put yourself in his place. What you calmly regard as an incident of your daily work is to him, perhaps, the life of a parent or a child. If he lose his heart in his fear, small blame to him; if his alarm or agitation lead even to some hasty and irregular action, I say again, put yourself in his place. He does not know, as you do, either your cleverness or the vanity of his fears. A cripple more or less, a gravestone more or less, is nothing to the solar system, but it is all the world to him. A doctor is no less liable than another man to be called upon to explain himself, and the ruthless test of cross-examination has taught us to distrust big words and feel that if we cannot make a thing clear to an intelligent layman, then we do not know it ourselves. A shake of the head and a dark allusion to the liver will not now satisfy an intelligent patient, nor ought it

to do so. Avoid infallibility. There is no better test of a man's knowledge than his neat delineation of the shore-line of his ignorance. As a rule, a patient calls on you for information as well as skill; and, while you are incapable of brutal frankness, your sympathy will be wise enough to teach you to give your opinions candidly and clearly." Then, turning to the matter of medical study, he said, "The best doctor is the best artist, and the best medical artist is the master and not the servant of his sciences. Those practitioners who complain that we turn out men nowadays who possess wide scientific knowledge but are no medical artists, have right with them. They feel that a less learned assistant gains with them a facility in dealing with exigencies which puts the much-pondering prizeman to shame in the sick-room. Able and well-meaning young men get lost in the faddy therapeutics so much in fashion to-day; and while balancing the hourly drop of digitalis against the half-hourly half-drop of aconite, they vacillate and lose time, if they do not miss altogether some broad features of their cases which would have been plain enough to their father's surgery-boy. I will be bold enough to question whether a doctor may not think too much about his cases."

"A nice old lady once told me her doctor was so precious to her, he lost, indeed, his sleep of nights in thinking over her symptoms. I strongly suspected that doctor to be a lying humbug. So important are the intuitive appreciation of the main factors in a case, the relations between them, and their tendencies, that, without these, reliance on those facts which are at once more precise and more limited may be positively misleading. Students and young practitioners rely, as a rule, far too much on their preciser data, and so far the discovery of instruments of precision has some temporary disadvantages. Because they find albumen in some urine which measures up to a substantial quantity, they cry out, Bright's disease! or sugar, and they cry out, diabetes! or a patient who has had a stationary mitral murmur for years, and may have it for many more, comes to the doctor, who applies first a simple stethoscope, then tries to get to the inner meaning of it with a double-barrelled one, and forgets the while that it is not the instrument but the man at the rear end of it which counts. All his mind, however, he sends down the tube, and leaves none for the patient's own story, none for an estimate of the tone of the circulation in the several organs, none for the contours of the chest and its districts, none for the many little common-sense probable inferences which the case should offer him. He rushes to the alarm of heart-disease in all its terror, which, if not literally, is practically true." (How accurate Dr. Allbutt's statement here is the writer is in a position to know.) He continues: "Now,

gentlemen, not in heart-disease alone, but in the whole field of medicine there is no exact datum of any instrument of precision—nay, not even of the thermometer—comparable in value to the inexact suggestions of the radial pulse, taken not by the sphygmograph, but by the erudite finger. In enteric fever, for instance, the qualities and fluctuations of the pulse are far more trustworthy signs than the variations of the temperature. Take away from me my instruments of precision, and you cripple me; deprive me of my touch of the pulse, and you blind me.” Then he puts in a kindly word for the dunces of the school. They have to be looked after by class-rolls and weekly tests. They cut a poor figure at the College of Surgeons, but, although some may be dullards, the majority are not so; they mature later, and attain a solid success, while retaining a cheerful, hopeful, manly disposition which attaches and invigorates their patients. “A country practitioner once drove me ten miles to see a patient, and on our way he discoursed me as ably on the geology of the district as upon the difference between a reef-knot and a granny, and upon the true construction of a claret-cup. I knew he must be an admirable doctor, and I strongly suspect that in years gone by he was a dunce.”

Oliver Wendell Holmes evidently does not stand alone in his opinion about “late pears.” Nor is it the quick-witted rather precocious youngster who runs off with the prizes at school and college that makes the successful man of later years, whose judgment is trusted by all who know him. Dr. Allbutt’s address is one which is at once original and to the point.

J. MILNER FOTHERGILL.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A CONVERSATIONAL meeting was held, September 19, 1883, Dr. William M. Welch, President of the Society, in the chair.

STRANGULATED FEMORAL HERNIA IN A MAN.

Dr. William R. D. Blackwood read the report of an interesting case of strangulated femoral hernia in an aged patient, successfully operated upon.

Mr. B., aged 73, tall, thin, but bearing his years well, and with a previous history of good health, was taken ill with supposed cholera morbus on Saturday, August 11, 1883; but from the suppression of alvine dejections shortly after the seizure, and the rapid change of the vomited matter to a manifest stercoraceous fluid by the time his family physician, Dr. John Ivison, saw him, the diagnosis of the family was set aside for one of more grave nature. The gastric dis-

tress was very great, the desire to vomit urgent, and the act occurred at short intervals. Previously to his illness the gentleman had been extremely constipated, and the amount of liquid and semi-solid faecal matter ejected per orem was simply inconceivable, except to those who saw it. At each instance of vomiting a fair-sized wash-basin was half filled, and the total quantity thrown up before relief ensued was, to speak within bounds, fully three gallons, showing the enormous distention of the intestine which may occur in chronic constipation.

The case was believed to be one of obstruction, with possible invagination of the bowel, and efforts were made towards overcoming the difficulty and obtaining an operation in a normal direction, but without success. The question of strangulation by hernia was not at first accepted, because, although there existed an evident swelling at Poupart’s ligament, the size of it was so small as to be taken for an enlarged gland, the patient having had glandular enlargement previously. There was no local pain, no tenderness, no tension, no dragging sensation at the site of the swelling, no tympanites: in short, the usual local signs of strangulated hernia were absent. The little tumor, also, was movable to such an extent as to easily deceive one, even when closely examined. The doctor having asked my opinion as to the condition of the patient, we saw him together, and I coincided with him as to the difficulty in stating positively to the family the evidence of hernial strangulation; but, as the patient was rapidly sinking from exhaustion, we decided to make an exploratory incision and determine the nature of the enlargement, the justice of this being explained.

The patient was etherized, and, after cutting down to the sac, the mass was found to be an entero-epiplocele. The sac contained very little serum, and, considering the fact that strangulation had doubtless existed for at least thirty-six hours, the bowel, though highly congested, was in good condition. The gut was tightly nipped at the crural ring, and was nearly empty, which accounted for the small size of the tumor. The hernia was internal to the femoral vessels, but closely adherent to them. It was reduced with some difficulty, and pushed far up to clear the deep thrust of the needle in closing the wound. The stitches, four in number, were deeply taken, and the ring obliterated as nearly as possible. A compress of lint, wet with a mixture of Canada turpentine, oil of sweet almonds, carbolic acid, and glycerin (an excellent dressing), was applied under a spica bandage of the groin, and the patient made comfortable in bed. He reacted well from the operation, vomited freely once thereafter, and in an hour and a half passed an alvine dejection without pain or difficulty. The appetite returned moder-

ately at once, food was well retained, and his strength returned nicely. For forty-eight hours the wound did well, healing for one-half its length by first intention, but then inflammatory action set in and free suppuration ensued. In a week, however, the wound had closed, and the old gentleman was able to walk his room with comfort.

The diagnosis of femoral hernia is at times not easy, being, as here, liable to be confounded with enlarged glands or localized varix of the saphena. There was no impulse on coughing, no effort at reduction affected it, and, excepting only the very small tumor, all the local signs of strangulated gut were absent. The advanced age of the patient was against him, and his depressed vital power was a bad factor. The result shows the value of exploratory operation under the circumstances, and I believe that the attendant is unfaithful to his patient if he does not insist upon it in every suspicious case. The wound is of little account: it does not enhance the danger, which is already imminent, and it may, as here, save a valuable life.

Dr. Blackwood also exhibited a recent specimen of atrophying scirrhus of the mammary gland.

Dr. Charles M. Seltzer presented a specimen of aneurism of the posterior part of the ascending thoracic aorta, taken from a convict, 35 years of age, which had escaped detection on careful examination during life.

Dr. Benjamin Lee exhibited some curious mucous casts, resembling tape-worm, which had been discharged by a young lady who had been subject to hemorrhoids and hemorrhages from the bowels.

A CONVERSATIONAL meeting of the Society was held at the hall of the College of Physicians, Philadelphia, September 26, 1883, the President, Dr. Wm. M. Welch, in the chair. Dr. Henry Leffmann read a paper entitled "The Duty of the Hour."

DISCUSSION ON THE RELATION OF THE MEDICAL PROFESSION TO THE GENERAL USE OF ALCOHOLIC LIQUORS.

The President stated that the points presented for discussion were:

1. That the use of alcohol in any form and in any amount by persons in ordinary health is deleterious.
2. That the medical profession, by its lax attitude on this question, is responsible for much of the prevailing abuse of alcoholic liquors.
3. That if alcohol is to be used at all, it should be given as such, and the prescription should be made non-renewable, as with other powerful medicines.

Dr. J. T. Eskridge, in opening the discussion, said that Dr. Percy's experiments showed

that the free use of alcohol tends to prevent the solidifiability of fibrin, and thus renders wounds difficult to heal; and those of Vierordt and Prout, that less carbonic acid is given off in the exhalations by the breath under similar conditions. Bouchardat first pointed out that alcohol darkens arterial blood. These results were obtained by experimenting upon subjects whose stomachs had been overcharged with alcohol, or into whose veins the spirit had been directly injected. They show the poisonous effects of alcohol, and, reasoning from these, it by no means follows that the administration of small quantities well diluted is injurious to health. But observations are not wanting to prove the evil effects of alcohol on healthy persons when taken in small quantities for a considerable length of time. Prof. W. B. Carpenter, a strong advocate of temperance, in his admirable prize essay on the "Use of Alcoholic Liquors in Health and Disease," after describing the baneful effects of alcohol on mind and body, frankly admits that its temporary administration to persons in health, on certain extraordinary occasions, is attended with decided benefit. Prof. Miller, of Glasgow ("Alcohol: Its Place and Power"), arrives at conclusions almost identical with those reached by Prof. Carpenter.

I am satisfied that persons in health, under ordinary circumstances, do not need an alcoholic stimulus, and that, if its administration is attended by no good results, evil only follows the use of alcohol at such times; but, on the other hand, I am convinced that circumstances do arise when, if alcohol is properly administered to persons in health, its good effects far outweigh its evil, and that there are conditions, short of what we are accustomed to call disease, which are improved by the temporary and judicious employment of alcohol.

Bodily and mental labor that cannot be endured without resorting to artificial stimulants had better be left off; but times come in the history of many persons when they are not their own taskmasters. A great deal may depend upon a few hours' work. Tea and coffee may not be sufficient stimuli; and a little alcohol taken at these times will allow an extra strain being made upon the system. The use of alcohol must not be often repeated for the purpose of increasing the power of endurance. It must be remembered that a stimulus in these cases acts the part of the spur to the tired horse. It probably does not directly add force to the individual, but it enables him to call more upon his latent powers, and, of course, the exhaustion which follows is all the more profound by reason of the extra strain upon the vital forces, made possible by the use of alcohol.

Again, the appetites of some persons have been rendered capricious and those of others lessened, and the power of digestion weakened, by worry and over-mental exertion, so that

the simplest articles of food cannot be digested properly. To such the administration of a little wine, with a bitter tonic, before meals, for a week or two, and subsequently a bitter tonic given before meals, and wine during or immediately after the ingestion of food, is followed by admirable results. In all these cases the use of alcohol must be cautious and temporary, and not allowed to be continued longer than is absolutely necessary. I agree with the statement made by the reader of the paper to-night, that below sixty years of age a person is generally not benefited by the use of alcohol in health. I know, indeed, of a case in which it did not become necessary to resort to it before the ninetieth year.

In regard to the use of alcohol in phthisis, to which a casual reference has been made, I have very strong convictions of its value when properly employed. In this disease, when pulse is rapid and temperature considerably elevated, alcohol is contra-indicated; but in the more chronic cases, when respiration is difficult, and pulse and temperature nearly normal, its beneficial effects in prolonging life are evident to every one who has given it a fair trial. Prof. Flint speaks in the highest terms of alcohol in phthisis.

As a preventive of phthisis, alcoholic stimuli have their place and power. It is well known that, in the same family, several children, whose parents have suffered from phthisis, may die from this disease at about the same age. For these persons, if alcohol is occasionally employed judiciously whenever vital force falls below its normal in them, I have no doubt that in many instances the fatal disease might be prevented.

To the second proposition I may say that I do not know of any case in which the use of alcohol in disease, under direction of a physician, gave rise to drunkenness. Some time ago, Dr. Hamilton, in a discussion before this Society, mentioned a case in which a patient became a drunkard in consequence of the use of alcohol in typhoid fever, but it appeared on further inquiry that the man was an habitual drinker before the disease occurred. Lax prescribing, however, may easily become a serious error. It is important that, if alcohol is ordered, the quantity, form, and time of taking should be indicated. It should be taken only at meals. This periodic and formal use of it will make the patient willing to stop when required. I admit that if we consider that alcohol is injurious in health we must regard its use in social gatherings, and especially in those composed of medical men, as wrong.

In reference to the last point I cannot speak from experience. If the adulteration is as extensive as pointed out in the paper, then the author's view, that alcohol should be used as mentioned, is correct, I, however, doubt that we can make, extemporaneously, mixtures which will take the place of natural liquors.

Dr. Mills said: I would not wish to be regarded as an advocate of anything else but temperance in the best use of the word, but the question of the influence of the moderate use of alcohol upon intellectuality and the longevity of intellectual workers is one of considerable interest, from what might be termed a biographical point of view. During the International Medical Congress of 1876, one of the English delegates expressed the opinion, in words which I do not exactly recall, that the intellectual productions of men who did not use alcohol at all were not of a character to indicate the value of abstinence. Many distinguished men who have lived to a comparatively advanced age—the English Lord-Chancellors, German thinkers, and well-known American statesmen, for instance—used alcohol in moderation throughout their lives. I simply introduce this point for discussion. About the evils of the abuse of alcohol no doubt can exist.

Dr. Wood: I consider the first proposition advanced by the author of the paper to be untrue: it is entirely too sweeping. To say alcohol is deleterious in *any* form and in *any* quantity in health is to say that one would be injured by simply smelling a bottle of whiskey. I am fully convinced that we do not need alcohol in health, but indulgence in it moderately, on occasions, is probably no more hurtful than over-eating. I have seen, at social gatherings, total abstainers who, while standing apart from the general company and congratulating themselves upon their superior virtue in not indulging in stimulants, gorged themselves beyond repletion with the food set before them, much to their stomachs' distress.

The moral question involved is the old one of use and abuse: Whether we must forego the use of a thing because some one else abuses it, and are we to abstain from a certain amount of pleasurable indulgence because of the example which that indulgence offers to others? I do not believe in attempting to force total abstinence, because I do not believe that the movement will accomplish the desired result. Not long ago I was travelling in Kansas, and I met a prominent prohibitionist, a member of the Central Committee of the State, whom I questioned about the success of the prohibition movement, asking, *inter alia*, if they had destroyed the grape industry, as the law directed, in the wine-making districts. He replied that they did not expect to do this in those places. Here was an admission of the weakness of the cause; for where the manufacture and use of wine are now most active was the least hope of abolishing it. In the same car was a travelling salesman on the verge of delirium tremens, and I asked him as to the effect of the liquor-laws in Kansas. He replied, "I can get a drink of whiskey anywhere in Kansas for fifteen cents." The Scandinavian method of

dealing with the temperance question seems to me more practicable. In Sweden and Norway the country is divided into districts, in each one of which only one tavern is allowed. The licenses are sold at public auction. The temperance people have combined and bought up the licenses. They are obliged to open the tavern, but they can adopt such regulations as will prevent the excessive use of alcohol by those who frequent the place, and also employ all moral means to persuade men not to drink at all. I do not think that the adulterations of liquor are as harmful as has been stated by the lecturer. Liquors and wines are artificial products always.

I think that good liquors can be easily obtained. I do not agree with the proposition that medical men are responsible for the habit of drinking to excess: on the contrary, the example and teaching of the medical profession have done much to diminish the evils of intemperance.

Dr. O'Hara: In reference to the remarks of the last speaker, let me read the following from Richardson's "Induced Diseases of Modern Life," page 232: "Speaking honestly, I cannot, by any arguments yet presented to me, admit the alcohols by any sign that should distinguish them from other chemical substances of the paralyzing narcotic class."

If this view be correct, we can have no doubt that alcohol is injurious in health, and that it does not serve as food. We are too much under the ideas of Liebig in this matter. For my part, I cannot see that the total-abstinence movement is a failure, or that the views advanced in the paper are erroneous. They are the views which have been advocated by high authority, in the International Medical Congress in 1876, and other scientific bodies, for instance. The medical profession may be responsible indirectly for much of the excessive drinking, through the erroneous idea, now passing away, that it was food.

I have myself learned by experience the evils of too much confidence in alcohol, when I thought it was food, and now watch it closely as a medicine. As to the cases narrated by Dr. Eskridge, they cannot be regarded as cases of healthy persons, and the use of alcohol in the treatment of them is a question of therapeutics, not of hygiene.

Medical men may certainly accomplish a good deal by the teaching influence of example.

I recall an instance in which brandy was used for dyspepsia: the patient, it is true, got rid of the dyspepsia, but he complained frequently until the day of his death, which was superinduced by liquor, that he made a bad swap and would rather have held on to his dyspepsia.

The conclusions of Dr. Hunt's paper were adopted by the International Medical Congress, 1876, and ordered to be transmitted to the National Temperance Society, the

Women's National Christian Temperance Union, and the Friends' Temperance Union of New York. They were:

1. Alcohol is not shown to have a definite food-value by any of the methods of chemical analysis or physiological investigation.

2. Its use as a medicine is chiefly that of a cardiac stimulant, and often admits of substitution.

3. As a medicine, it is not well fitted for self-prescription by the laity, and the medical profession is not accountable for such administration or for the enormous evils arising therefrom.

4. The purity of alcoholic liquors is, in general, not as well assured as that of articles used for medicines should be. The various mixtures when used as medicines should have a definite and known composition, and should not be interchanged promiscuously.

Dr. Tyson: This question is one very difficult to discuss; both parties are apt to go to extremes. Dr. O'Hara's remarks are a case in point, for the injurious effects to which he alludes are the effects of the use of alcohol in excess and not in moderation. It must have been the experience of all practising physicians to see many cases which are benefited by the moderate use of alcohol, especially at meals, while in many aged persons its use is very appropriate, and even necessary. I am not prepared to deny altogether the correctness of the second proposition offered in the paper. I think there may be some ground for it, yet I do not know a single case in which the recommendation of the use of alcohol in disease has resulted in establishing a habit of drinking. I recall a case in which a gentleman was advised by a non-medical friend to use whiskey for dyspepsia. It was tried, and, finding good results from it, he continued using it in small amounts daily: the use was kept up until one day the patient found the bottle empty. He missed his usual dose so greatly that he was forced to realize that he had been drinking, and never used the liquor again. It may be laid down as a rule that it is not safe for physicians to advise the regular use of alcohol for dyspepsia: it may lead to a habitual use of stimulants. As to the third point, I think that, in view of the fact that it is still possible to get pure wines, especially if we are satisfied with domestic wines, the flavor and other properties which made them more acceptable to the patient justify their continued use; but I for one am willing to try the effect of pure alcohol, properly diluted, in cases where alcohol only is indicated.

Dr. Hamilton: Moderate drinking, it must be remembered, is very often the road to immoderate drinking, and therefore the physician, whose influence in this connection is paramount, should sedulously avoid the too frequent and too liberal use of liquor, especially in young subjects. In the low forms of fever, or in chronic wasting disease, such,

for instance, as pulmonary consumption, to which allusion has been made, it is often of great advantage, and in the latter disease, where expectoration is profuse, but unaccompanied with much fever or difficulty in breathing, it may prolong life for an indefinite period. The custom of drinking in the wealthy and fashionable circles may still be said to prevail with tyrannic power, and in ordinary social reunions the same practice is common. The influence of wealth and fashion is dominant, and, until some amelioration in this connection is manifest, no general temperance reformation need be looked for in the people at large.

The allusion to the adulteration of wines and stronger liquors was deservedly made, but it occurs, doubtless, much more frequently in regard to the finer and more costly than to the cheaper liquors, and the perfection to which this adulteration has attained is simply notorious.

Dr. James C. Wilson: I am much pleased to see this subject before the Society. It is a subject which ought to be agitated, because the agitation will bring out the truth. I think that the propositions rather overstate the case, and somewhat weaken the points advanced. Independently of law, church influence, and local politics, a wide-spread popular sentiment is developing in favor of temperance, but not of total abstinence. A feeling against excessive indulgence is growing steadily in the community. It is now considered "bad form" to drink to excess at social gatherings, and young men especially are much more restricted than formerly. The three-bottle men of earlier days are now unknown. It is, however, going to an extreme to put the proposition that the use of alcohol in any form, and to any extent, is deleterious. Many persons can use alcohol in moderation, and derive comfort from it, without injury. I do not agree with the second proposition. Respectable medical men are not lax in their attitude on this question, but are accustomed to caution their patients in regard to the dangers of the use of alcohol. Most of them direct the amount to be taken, and fix a time for discontinuing the use, just as they do with other powerful drugs. As regards the suggestion to use alcohol alone, it appears to be open to some objections. It is not possible to imitate the different wines. No formula of the Pharmacopœia or prescription could reproduce the perfect mixture in natural wines, which are often so specifically beneficial.

Dr. Frank Woodbury said: I have been much interested while listening to the paper, and, in the main, sympathize with its teachings. I think that the propositions submitted for consideration were purposely exaggerated so as to excite discussion, since they are not logical deductions from the paper, and, indeed, have not been presented as such. The alcohol question is a complex one: it is a

great social and moral problem, as well as a scientific and medical one. The subject as presented this evening has at least three aspects: the use of alcohol in any quantity in health—this is a physiological question; its employment by physicians—which is a medical question; and the right of physicians to prescribe it—a moral question. This moral question is really the principal one of the paper, as is shown by its title, "The Duty of the Hour." With regard to the question as to its injurious effect when used in health in any quantity, I would ask, first, what is meant by a state of health? If a physiological definition is accepted, then no person living under the artificial conditions of civilization can be in a state of perfect health. Ordinary health is merely an approximation towards physiological health; and if the utility of alcohol is acknowledged in the condition of disease (which is merely any departure from the healthy standard), then the first proposition is answered by the lecturer himself, in the negative. Then again, concerning the use of alcohol "in any quantity," I think it worth while to recall the fact that not only is it without injurious effect in very small doses, but that in reality the organism cannot escape from imbibing alcohol; it is omnipresent—it is in fresh bread and in ripe fruits, and even traces have been found in the air we breathe, provided there exist a certain amount of organic matter and the conditions of temperature and moisture necessary to fermentation. Even in the muscular tissue and urine of total abstainers a substance is present chemically indistinguishable from alcohol.

In large doses every one admits that it is capable of destroying life by its own properties when taken into the system, and it is therefore a poison. Its use in much smaller doses, it must be admitted, may not prove incompatible with the enjoyment of long life and ordinary health; but in many cases its constant use directly induces disease and tends to shorten life. The fact that a substance is a poison, however, is not sufficient in itself to forbid its use in disease, provided that it be given in accordance with the teachings of science and experience. The physician with the longest experience of any present has just expressed his deliberate opinion that it is useful in low conditions of vitality and in slow convalescence.

With regard to the right of the physician to prescribe alcoholic liquors, the moral aspect of the subject, I hesitate to express an opinion, for fear of being misunderstood. I would suggest, at the outset, that in reality the treatment is not so entirely under the control of the physician as is implied by the question. Is it not the fact that it is the patient who employs the medical attendant, and if he is not treated in accordance with his ideas of propriety he becomes dissatisfied, loses confidence in his physician, and engages another?

A rough illustration may be given : When a Chinaman falls sick, he, as a rule, will, if possible, secure the services of the kind of physician that his parents and friends approve of. A sick Indian in the same way prefers the treatment of his medicine-man to that of the most scientific post physician. Is it not also true that in more cultivated communities the physician who is called upon in the hour of sickness is the one whose thoughts and prejudices best agree with those of his clients? Patients certainly should not be allowed to dictate in the details of treatment, but their unrelinquished right to approve or reject the general plan of treatment cannot be disputed. It may seem like a humiliating admission, but it is true that in a community where the taverns far exceed the bakeries, total-abstinence physicians will have more opponents than clients.

I hope that nothing that I have said will convey the impression that I approve of the use of alcoholic liquors in disease, given merely with a view to gratify the patient: if ordered at all, they should be given to obtain the therapeutical action of ethylic alcohol, which, on account of variation and strength and adulteration in ordinary liquors, may be best given in the form of dilute alcohol in order to secure both purity and exact dosage. This, I have learned, has been largely employed in Bellevue Hospital, where it was introduced by Dr. Gillette; by its use the medical effects of the drug are obtained, and the danger of encouraging the use of ordinary liquors is to a large extent obviated. In conclusion, I wish to express the opinion that the second proposition should be reversed, and it should read, "Physicians, deserve great credit for inculcating more correct and scientific ideas with regard to the use of alcoholic liquors by the community." The great advance in the cause of temperance, in my opinion, is very largely due to the teachings of certain prominent physicians and the precepts and example of the great body of the profession.

Dr. Leffmann, in closing the discussion, said: I am dissatisfied with the direction the debate has taken, for too much time has been given to the discussion of the value of alcohol as a remedy, a point which I expressly excluded. While the propositions which I laid down are my convictions, and I believe they will all be ultimately recognized as true, yet I purposely worded them in an extreme form to make the debate more definite. No one, however, is justified in giving to the first proposition the strained meaning that Dr. Wood put upon it, namely, that smelling a bottle of whiskey would be held as injurious. The language should be judged according to its intention. The remark quoted by Dr. Mills, in regard to the literary abilities of total abstainers, is also unworthy of the dignity of the question, and is not argument.

Dr. Woodbury's suggestion that alcohol must be used because patients expect its use is surely not the true principle of medical practice. Patients are not to be the judge of anything in treatment. The success of homœopathy and kindred delusions is largely due to the erroneous and absurd view that patients may elect the system of medicine on which they are to be treated. Neither can one regard the fact of the occasional existence of alcohol or alcohol-like bodies in organic matter, in urine or in muscular tissue, or in fresh bread (which latter I doubt very much), as any argument for its use in health as a beverage. Several of the speakers have apparently regarded the paper as declaring the adulteration of liquors to be harmful; but this was not the ground taken. On the contrary, in two papers on alcohol previously read before this Society, and in papers read elsewhere, I have pointed out that the adulterations are cheats rather than poisons. It is the uncertainty and deception to which I call attention.

Although objection has been made to the third proposition on the ground that alcohol alone or simply diluted will not answer, yet we have these objections well refuted by the fact just stated by Dr. Woodbury, that in one of the New York hospitals such a preparation is regularly and successfully used.

The second proposition has been misunderstood. It has been taken to mean that the use of alcohol in disease under medical advice has resulted in drunkenness; but this is not the meaning. It is the habit of moderate drinking in health that makes drunkards, and it is to the indifference of the medical profession to this habit that the second proposition relates.

The whole question, it seems to me, is a most important one. The terrible effects of alcohol are seen in all directions, and if the restriction of it is needed—and I do not see how any one can doubt that fact—such restriction must only come by active assistance of those who know the facts best. It will never do to temporize with vice. No method will answer with any form of crime or vice except continuous, unrelenting opposition. It is a mistake to suppose that wide-spread and deep-rooted habits are unconquerable. Did time permit, it could be shown that traits of human character, as vicious and deep-rooted as the tendency to drinking, have been eradicated by persistent effort; and what has thus been done can be done again. I am fully of the opinion that the tavern finds its best support in the idea so general in the community that physicians consider the regular use of a little alcohol not injurious. When the medical profession is true to itself, and teaches that alcohol should never be used except for a specific purpose and under continued medical advice, the tavern will lose its best hold on the community.

The statement of Dr. Wood that he is fully convinced that we do not need alcohol in health, and that indulgence in it moderately on occasion is no more hurtful than over-eating, certainly leans in favor of my first proposition.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

STATED MEETING, THURSDAY, October 4, 1883.

The PRESIDENT, R. A. CLEEMANN, M.D., in the chair.

PORRO-MÜLLER OPERATION.

DR. W. H. PARISH reported a Porro-Müller operation performed by him upon a dwarf at the Philadelphia Hospital, June 30, 1883, the patient surviving only forty-eight hours. He presented these specimens from the case, including the uterus, the abdominal incision (which had united) and surrounding wall, the stump of the cervix in position at the lower angle of the wound, the entire external genitals and mons, including the vagina and bladder. The ureters were found entirely free. The child had arrived at about two weeks more than the eighth month of utero-gestation. It was small, and lived for three weeks. He gave the clinical history of the patient, from which the following report of the operation is taken:

After etherization the bladder was emptied with the catheter. An incision was then made in the median line of the abdomen, seven inches in length, extending from two inches above the symphysis pubis to about one inch above the umbilicus, passing to the left of the umbilicus. The slight bleeding from the lips of the abdominal incision was controlled by artery-compressors before opening the peritoneal cavity. The absence of intestine from in front of the uterus was ascertained by percussion before making the incision. The uterus was easily raised from the abdominal cavity.

Owing to the anterior lumbar curvature, and to the length of the incision, it was impossible completely to prevent the escape of intestines. After the uterus had been turned out, a protector made of two layers of flannel, with an intervening layer of protective silk, was placed over the abdomen,—the object being to avoid chilling, and to prevent the escape of blood and other fluids into the peritoneal cavity. This protector, when used, was wrung from a warm carbolized solution. The next step was to place around the cervix the wire of an *écraseur*, and to constrict the tissues in its grasp to such an extent as to stop all circulation of blood through the uterus without cutting through the peritoneum. This step required speed, care, and judgment. The liability of a loop of intes-

tine or of omentum to be caught by the constricting wire had to be carefully guarded against. Immediately that sufficient constriction had been secured, a short incision was made with a pointed bistoury through the antero-uterine wall down to the placenta, for the placenta proved to be attached anteriorly. The incision was then rapidly extended, from near the neck to the fundus, with a probe-pointed bistoury, guided by two fingers of the left hand introduced into the incision. The blood pent up in the uterus by the constricting wire escaped freely, but did not enter the abdominal cavity. The incision passed to the external surface of, but not through, the placenta. The hand was immediately introduced into the uterus through the exposed membranes at the fundus, and the child quickly turned out, the placenta being in this manœuvre detached in main from the uterus. The cord was promptly tied and cut, and the child handed to Dr. Keating. It was asphyxiated when delivered, and presented a very unpromising appearance.

It, however, quickly breathed and cried under the efforts of Dr. Keating at resuscitation. The rapid resuscitation was effected by alternately dipping the child in basins of hot and of cold water. After removing the infant, the uterus, with both ovaries and both tubes, was amputated a half-inch above the constricting wire: this point was about at the internal os. It was then seen that the wire had completely controlled the circulation, and not a drop of blood escaped from the stump of the uterus.

The next step consisted in passing obliquely through the stump two steel pins five inches in length, one above, the other below, the wire. After this a strong carbolized silken cord was passed around the stump, in the line of the wire, and partly tightened. The wire was then cut and removed, and the silk cord then very firmly tightened and securely tied. Special care was given to the tightening of this cord and to the tying of a secure knot. The ends of the pins rested laterally on the abdominal walls, and under the ends, on each side, was placed a piece of sheet-lead. The stump was thus secured outside of the abdominal cavity, and rested at the lower angle of the wound. New carbolized sponges on handles were introduced into the peritoneal cavity, down into Douglas's pouch, but the entire cavity was free from blood or other fluid.

The abdominal wound was then closed by deep and superficial silver sutures. The deep ones were introduced so as to include the peritoneum. During the introduction of the deep sutures, flat carbolized sponges were introduced beneath the incision, so as to catch what oozing might occur from the needle-punctures. The external portion of the uterine stump was brushed over with carbolic acid, and then invested with lint saturated

with carbolyzed oil. A strip, two inches wide, of dry carbolyzed lint was placed on the incision; over this a few strips of rubber adhesive plaster were applied transversely, over these a thick layer of carbolyzed cotton, and over all a flannel binder. The patient was put to bed, and surrounded with pans of hot water. Dr. Montgomery took charge of the patient's general condition during the operation, and administered during its performance four hypodermic syringefuls of whiskey. He reports that the time taken up in the operation, from the beginning of the abdominal incision until its complete closure, occupied forty minutes. During the operation the pulse ranged from 100 to 128, the greater frequency being during the making of the incision in the abdominal wall, and was probably due to impeded respiration. The constriction of the cervix had no appreciable effect upon the pulse. Soon after being put to bed, the pulse was 132, but in two hours was 108 per minute, and of good volume. The respirations during the anæsthesia became disturbed and imperfect, producing considerable cyanosis, and probably causing increased frequency of the heart's action.

The patient rallied well, as was shown by return to consciousness, by bodily warmth, and a fair pulse. For about sixteen hours her condition seemed very favorable, excepting that the kidneys had ceased to act. At the end of twenty-three hours there was marked change for the worse; the mind wandering, pulse 140, temperature 100° F. An inspection of the dressing at that time showed some oozing from the stump,—perhaps six ounces,—but it had then stopped. An additional ligature was placed around the stump, and one of the uterine arteries was separately ligated, the other could not be found; the stump was also brushed over with Monsel's solution. There was no subsequent oozing. That there should have been any loss of blood in this manner was a surprise to me, as the original ligature was so very firmly tightened and secured, and had for a number of hours after reaction so perfectly controlled all bleeding. There was marked atheroma of the vessels of the stump, as was revealed post mortem. After the twenty-third hour the patient grew progressively worse, became uncontrollable and delirious, had convulsive manifestations, and died in coma. There was no vomiting until twenty-six hours after the operation, and it recurred only once. She experienced but slight pain, and sulphate of morphia was given in small quantity,— $\frac{1}{4}$ gr. hypodermically, soon after the operation; again $\frac{1}{4}$ gr. at the end of eleven hours,—and subsequently, about the thirty-sixth hour, because of the great jactitation and the difficulty of keeping the patient in bed. The morphine was given hypodermically in such small amount that the coma could not have been due to it. Eight hours after being put to bed

the urine was drawn with the catheter. Subsequently it was introduced at different intervals, but on each occasion the bladder was empty, and it was also found empty at the post-mortem examination. Only three ounces of urine were secreted after the operation. The patient survived forty-two hours.

Dr. R. P. HARRIS remarked that this was the only Porro operation that had been complicated by diseased kidneys. The case was an unfavorable one in consequence of this complication. The albuminous character of the urine was supposed to be due to mechanical interference by the enlarged womb, but unfortunately this was not so. The bad habits of the patient had led to a general disease of the arteries as well as of the kidneys. The former were atheromatous. The Porro-Müller operation has been performed thirty-four times; the unmodified Porro, eighty-two times,—total one hundred and sixteen cases, of which forty-eight per cent. have been successful in saving the lives of the mothers. When the pedicle or stump is dropped, it ceases to be a Porro operation. Of thirteen cases in which the stump has been dropped, eleven have been fatal. Dr. Godson is writing a full history of this operation, including the many experiments which have been made on animals to determine the best method for each step of the operation and the causes of death. Dr. Porro has saved four out of five cases in his own hospitals. In the Milan Hospital nine were saved out of twelve. In Germany the success has been poor, but in Austria better.

Dr. O'HARA asked why the Porro operation should be modified, when it had been so successful in the hands of the originator.

Dr. HARRIS: Dr. Muller was called upon to operate in a case in which the fœtus had been dead for some time and was putrid, the uterus being distended with gas. To prevent any septic matter finding its way into the abdominal cavity, he enlarged the abdominal incision, lifted the uterus out of the abdomen, and used cloths around it and over the wound before incising the uterus. This patient recovered. The mortality this year has been very slight.

Dr. E. E. MONTGOMERY had been associated with Dr. Parish in this case, as one of the hospital staff, and at first thought the case should be allowed to go on to full term before operating, and that Cæsarean section or laparo-elytotomy, as practised by Dr. T. G. Thomas, should be the selected form of operation, but Cæsarean section has been very fatal in large hospitals, doubtless because it is generally a last resort after the patient has been long hours in labor, and for that reason is dangerous. But if a large drainage-tube were passed through, entering at the abdominal incision and out of the vagina, and a constant flow of antiseptics kept up, a good condition might be secured.

During the operation a few modifications suggested themselves. One of these was to divide the cervix uteri by a V-shaped incision, the peritoneal surfaces being united over the wound, a flat Peaslee drainage-tube being introduced and the stump dropped. Dr. Harris tells me that Schroeder has tried this, and that it has been done twice by —, once successfully.

He thought the wire of the *écraseur* passed around the cervix before removing the child a source of danger to the latter, as well as being likely to embrace a loop of intestine.

Dr. HARRIS, in criticising the plan of dropping the stump, called attention to the fact that the portion of uterus embraced in the ligature is not a pedicle. It is a stump, and will continue to contract, and oozing of blood or even profuse hemorrhage is liable to occur. It has been found impossible to prevent this by any form of ligature that has been tried. If the stump is dropped, this hemorrhage or oozing will take place into the abdomen, and will be a certain cause of death. Dr. Isaac E. Taylor came near success, but his patient died from thrombosis on the twenty-sixth day, during an attack of phlegmasia alba dolens. It would be very desirable to avoid the dragging on the abdominal wound.

Dr. MONTGOMERY gave a short *résumé* of the cases treated by dropped stump, and the causes of death in them.

Dr. PARISH remarked that the disease of the kidneys was undoubtedly the cause of death, the implanting of the acute condition caused by pregnancy upon the previous chronic disease. He also spoke of the possible deleterious effect of the ether upon the system laboring under such a condition of the kidneys. It made the administration of ether in such cases a very serious matter.

Dr. PARISH also exhibited specimens from a case of

EXTRA-UTERINE PREGNANCY,

and made some remarks upon the history of the case. He had attended the patient in her first labor, seven years ago. She was a brunette, of very restless and active habits and disposition, and was quite uncontrollable. She was up and about her house a few days after her labor, and the result was subinvolution, which persisted until her death. During the interval she had passed out of his care, and had been subjected to local treatment, including the use of sponge tents. These had developed pelvic inflammation, and later she was troubled with frequent micturition and dysmenorrhœa. She afterwards came under his care again for treatment of these troubles, and on one occasion he had applied leeches to the cervix, and gave her positive orders not to leave her bed; but festivities were going on, and she went down and assisted in making ice-cream and cake, and later in eating them. This indiscretion was followed by a second

metritis. He afterwards treated for the dysmenorrhœa by numerous minute punctures of the cervix, and the application of tincture of iodine, and the introduction of a sponge tent. The next period was not so painful, and the second was missed. He told her she was probably pregnant, but two weeks later a slight show occurred, and, fearing an abortion, he advised rest in bed: she refused an examination and would not be quiet. The flow continued, but did not increase, but there was pain in the pelvis in addition. Eleven days after the flow commenced, a sudden attack of intense pain occurred; the patient was completely prostrated, and was carried up-stairs. As he was not at home, Dr. O'Hara was called in, and used morphia hypodermatically. He found, on examination, a mass in the posterior part of the pelvis; the uterus was pushed forward against the pubes. He diagnosticated rupture of a Fallopian pregnancy cyst and internal hemorrhage, and gave opiates to relieve the intense pain. The pallor and exhaustion became more pronounced, and death occurred thirty hours after the first symptom. Other physicians who saw the patient did not agree with Dr. Parish in his diagnosis. The autopsy revealed no recent peritonitis. There was blood in the pelvic and abdominal cavities: this had escaped from a ruptured cyst of the Fallopian tube. The foetus exhibited was found in the pelvic cavity. The position of the cyst was such that it would have been an easy operation to open the abdomen and ligate and remove the cyst and ovary and cleanse the pelvic cavity. The Fallopian tube involved is dilated, except at the uterine extremity. The other tube is occluded at the fimbriated extremity. Inflammatory bands derange the relations of the different pelvic organs. We have here the history of inflammatory processes changing the epithelial linings and relations of the Fallopian tubes to the uterus and ovaries as predisposing causes of extra-uterine pregnancy.

Dr. HARRIS remarked that the hemorrhage after conception, the peculiar location of the pain, and the pallor make the diagnosis an easy one. He had one patient that recovered spontaneously. The operation suggested by Dr. Parish has been performed once successfully. Dr. T. G. Thomas made the diagnosis and wished to operate, but the husband, a physician, differed in opinion, and would not consent. That patient lived sixty hours. Dr. Playfair advises the operation.

Dr. O'HARA saw the case early, and could not make such a diagnosis. He saw no sign of internal hemorrhage then. He thought of peritonitis or cellulitis. There had been no history of a cast of the uterus. He did not see how a positive diagnosis of extra-uterine pregnancy could have been made at that time. The patient was certainly going to die, and he would approve of an exploratory operation.

Dr. PARISH remarked that Dr. O'Hara was perhaps right: he (Dr. P.) was the only physician present who looked at the case in that light; all the others disagreed and had their reasons. If this diagnosis of a probable extra-uterine foetation had been made early, before the accident, then when the acute symptoms supervened a quick diagnosis could have been made as to the cause of the pain. He described a fold of peritoneum found behind the uterus, and, as the clot had the appearance of different ages, portions being yellow, he suggested that an extra-peritoneal hemorrhage had first occurred under this fold, perhaps ten days before the intra-peritoneal hemorrhage which was the cause of death.

Dr. BEATES exhibited for Dr. Boardman Reed, of Atlantic City, New Jersey, a tumor of the uterus, which the latter supposed to be an early stage of carcinoma; but no microscopic examination of the specimen has been made.

Dr. BEATES reported the case of an infant which appeared well and hearty at birth but died in collapse on the third day. An autopsy revealed acute gangrene of the mucous surface of eight feet of the ileum; hemorrhage had occurred into the intestine and was the immediate cause of death.

W. H. H. GITHENS,
Secretary.

NEW YORK PATHOLOGICAL SOCIETY.

A STATED meeting was held, October 24, 1883, George F. Shrady, M.D., President, in the chair.

SARCOMA OF THE CHOROID AND VITREOUS BODY.

Dr. CHARLES HEITZMAN presented a specimen of sarcomatous degeneration of the choroid and of the vitreous body, occurring in a man about sixty years of age, upon whom enucleation had been performed, but, other organs becoming affected, the patient succumbed. Dr. Heitzman took occasion to emphasize the view which he had for some time held, that the vitreous body is alive; and he thought this specimen was an evidence of that fact, inasmuch as a distinct fibrous capsule separated this body from the choroid growth. Through this capsule cells could not have penetrated, and none were seen in that portion of the field under the microscope.

NEPHRECTOMY BY ABDOMINAL INCISION FOR FLOATING KIDNEY.

Dr. GILL WYLIE presented a kidney removed from a patient whom he saw in the country in August last. She had been treated for uterine and ovarian disease, but these organs were not found to be affected. The patient had for some time suffered extreme pain in the right side, calling for chloroform in addition to opium as an anodyne. At the age of fourteen she had had pneumonia, but

there were at present no signs of pulmonary disease, nor was there a family history of this affection. She was thirty-four years old, the mother of four children. In the dorsal position nothing abnormal was discovered, but when the patient assumed the upright posture she complained of pain, and remarked that she thought the doctor would then be able to feel a tumor in the abdominal wall. A floating kidney was then recognized, and was supposed to have caused pain by becoming strangulated. It was extirpated through an abdominal incision to the right of the umbilicus, the peritoneum being opened a distance of three inches. The vessels were ligatured with silk and the abdominal wound closed. The patient did well. The temperature rose but slightly. Twenty-four ounces of urine were secreted daily, at first, and at present about thirty-six. The stitches were removed on the eighth day. The patient suddenly sprang from the bed, in a dream, and caused partial separation along the line of union, and some hemorrhage took place; but, aside from this accident and a small abscess in the abdominal wall, she was doing fairly well. Pain disappeared from the right side. There was now slight pain in the region of the left kidney, but of rather an indefinite kind. The urine had formerly contained albumen and pus, and it at present contained some pus, pointing to possible affection of the left kidney, but possibly to some degree of suppuration in the ligatured ureter. The left kidney was in its normal position. Dr. Welch examined the organ removed, and found it the seat of tubercles and the bacilli tuberculosis.

Dr. JOSEPH HOWE thought the symptoms might have been due alone to the presence of the tubercles without strangulation.

Dr. A. JACOBI would not have the impression go forth that the presence of a floating kidney always justified nephrectomy; on the contrary, extirpation is seldom called for, whereas movable and floating kidneys were very common. He himself had seen as many as thirty, mostly in women, some in children, not so many in men, and in not a single case had an operation been demanded. The patient had better wear a bandage and put up with slight discomfort than to go with but one kidney.

Dr. WYLIE coincided with the remarks made by Dr. Jacobi, except that he did not believe that much was to be gained by a bandage. It was not improbable that a bandage higher up, in the form of a corset, had something to do with causing the condition.

Dr. HEINEMAN saw as many as half a dozen cases of floating kidney, principally in women, at Dr. Clark's clinic every season. When tuberculosis affects one kidney it is likely also to affect the other; and it was not improbable that the remaining organ was the seat of disease in this case.

STRANGULATED OBLIQUE INGUINAL HERNIA.

Dr. JOSEPH HOWE presented the specimen, the chief interest of which was the fact that the patient had suffered with the strangulation for five days before seeking for medical relief, supposing the difficulty to have been due to constipation. He was 45 years of age, and said the hernial tumor had been there for thirty years, and had never before given him any trouble. About three or four inches of gangrenous gut were removed, and the ends stitched to the sac. The patient had been vomiting, suffering extremely, and was in a state of partial collapse. It was not probable that he could recover. About two years ago Dr. Howe presented a similar specimen to the Society, the man having gone without aid for five or more days. He died soon after the operation.

Dr. WYLIE had seen a patient in the country in whom an artificial anus had formed at the seat of a strangulated hernia, his physician refusing to operate on the day he saw the patient, because, as he said, it was too cold. The patient was still confined most of the time to his bed, more than a year since the accident.

Dr. HOWE replied to a question by Dr. WYLIE, that he would not attempt to close the fistula, and if it were not large enough it should be increased in size.

CONTRACTION OF THE SEMILUNAR VALVES,
CAUSING PULMONARY STENOSIS.

Dr. R. VAN SANTVOORD presented the heart removed from a child which died on the twentieth day. It was well nourished, the pulse and respiration rapid, a loud murmur at the junction of the sternum and third and fourth costal cartilages, transmitted all over the chest. Cyanosis developed, and the child died, apparently of heart-failure. The valves at the pulmonary artery were much thickened and shortened, causing stenosis. There was marked hypertrophy of the right ventricle; there was no atelectasis.

TWO CASES OF RUPTURE OF THE HEART.

Dr. FERGUSON presented the specimens, the first one of which was removed from a man who had had an attack of dyspnoea and about two hours afterwards was found dead in the water-closet. The body was well nourished; the kidneys were atrophied, giving well-marked signs of diffuse nephritis; the lungs were congested; the pericardium contained a large amount of blood; the heart-walls were pigmented and showed signs of general myocarditis. Near the apex in the left ventricle was a rupture three-quarters of an inch in length.

The other specimen belonged to a man who had received an injury on the back of the hand, tearing away the soft structures and exposing the extensor tendons. The wound was dressed antiseptically, and the patient did

well the first three weeks, but the muscles of the face and neck and thorax then became contracted, breathing was interfered with, and the patient died in one of the tetanic convulsions. At the autopsy the brain and cord were found congested, the lungs oedematous and congested; the pericardium contained a large amount of blood; the heart was normal, except that in the right ventricle there was a small rupture, admitting a probe. In the one case, therefore, the rupture was due to disease of the cardiac muscle complicated by diffuse nephritis; in the other, to the convulsions of tetanus.

VERTEBRAL ABSCESS—DEATH WITH CYANOSIS.

Dr. H. D. CHAPIN presented a specimen removed from the body of a child nearly three years of age, which died of symptoms of cyanosis. A few weeks previously it had been brought to the Dispensary with cough and a wheezing sound over the chest, but on physical examination no symptoms were found except bronchial and tracheal râles. There was no cyanosis at that time, and no dysphagia. The child had improved under treatment, but the mother said that while playing it suddenly became blue and died. At the autopsy a large abscess was found, affecting the first and second dorsal vertebrae; there was a tumor composed of a bronchial gland which had undergone cheesy degeneration; there were also tubercles in the lungs and trachea.

CARCINOMA OF THE STOMACH, LIVER, SPLEEN,
AND INTESTINE.

The specimen was presented by Dr. Carpenter for Dr. STICKLER. The patient was a man, 52 years of age, who first began to suffer from pain in the region of the stomach; the pain soon extended into the right hypochondrium. Anodynes and counter-irritants constituted the treatment. The patient rapidly emaciated; vomiting occurred, but not of blood or dark-colored matter; the cancerous cachexia developed. There was constipation and scantiness of urine. Later an irregular tumor was felt in the region of the pyloric end of the stomach. The patient died at the end of fifteen months after the commencement of his symptoms, and at the autopsy the liver, the intestines, the spleen, and the stomach were the seat of cancerous degeneration, the latter organ and the liver being greatly diminished in size. The cæcum was much constricted, which would account for the extreme constipation which had existed.

SCARLET FEVER IN HORSES.

Dr. PETERS reported further on this subject, stating that since the last meeting he had conversed with several of the veterinary surgeons in the city, and most of them recognized the symptoms which he had before described

under the head of scarlet fever, but all were not agreed as to the nature of the disease; one surgeon had called the affection measles, having been more familiar with that disease than with scarlet fever in the human race. Dr. Peters thought it probable that certain symptoms classed as a peculiar disease, and followed by what was acknowledged to be scarlet fever, were only an early stage of this affection. Scarlet fever was more apt to be found in the sale-stables, where many horses were being constantly brought in from the country, than in the car-stables, where only from three to ten were brought in at a time.

REVIEWS AND BOOK NOTICES.

INDEX-CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, UNITED STATES ARMY. Authors and Subjects. Vol. IV., E to FIZES. Washington, Government Printing-Office, 1883.

The fourth volume of this magnificent work has lately appeared, containing 4802 authorities, representing 1926 volumes and 3885 pamphlets; it also includes 12,361 subject-titles of separate books and pamphlets, and 48,977 titles of articles in periodicals. This volume, like the others, is a royal octavo of over a thousand double-column pages, handsomely printed upon heavy tinted paper, in a manner in every way worthy the work itself, which is monumental in character. In looking over its pages, we observe that the bibliography of some special subjects is remarkably full, quite discouragingly so sometimes when one happens to want to write an article upon a topic which deserves careful preparation. We also are attracted by the titles of rare and valuable books, many of which were secured through the personal interest and attention of the librarian, Dr. Billings, who has put the entire profession under obligation for his zeal, industry, and devotion to his work.

A GUIDE TO AMERICAN MEDICAL STUDENTS IN EUROPE. By HENRY HUN, M.D. New York, William Wood & Co., 1883. 8vo, cloth, pp. vi., 151.

This little work abounds in the practical information that is needed by Americans who intend going to Europe to complete their medical studies. It contains knowledge of the kind that a new-comer is most anxious to gain, and often finds it so difficult to acquire, with regard to the various schools, their faculties, fees, hours for lectures, requirements, etc., of all the principal medical centres in Europe, especially in Germany. This book will prove very useful to the American student in a foreign city, and may save him from loss of time and unnecessary trouble.

THE MEDICO-LEGAL JOURNAL is the title of a handsome monthly published under the

auspices of the Medico-Legal Society of New York, the first number of which appeared in August. The September issue has for a frontispiece a handsome steel portrait of the late Dr. James R. Wood, of New York. From the appearance of the table of contents, and general indications, it is evident that the new arrival has come to stay, and we cordially welcome it to our exchange-list.*

GLEANINGS FROM EXCHANGES.

SURGICAL DISEASES OF THE KIDNEY.—At the annual meeting of the British Medical Association, Mr. Clement Lucas said that the credit of having awakened a new interest in renal diseases, and of having, by experiment on the lower animals, made sure of his ground, was due to the late Professor Simon, of Heidelberg, who in 1869 successfully performed nephrectomy for the cure of a fistula of the ureter following ovariectomy. Since then, extirpation of the kidney has been performed upwards of a hundred times. The operation of nephrotomy has been much more frequently undertaken, and the removal of a stone from the kidney, which used only to be attempted when a sinus or tumor existed, has been several times successfully performed before the kidney has suffered any severe damage.

In casting a glance over diseases of the kidney to determine which might admit of surgical treatment, it is necessary to exclude at once all such diseases as attack equally the two organs: hence the various degenerations included under the name of Bright's disease and lardaceous disease must ever remain outside the province of renal surgery. On the other hand, conditions which disturb the functions of one organ only, for the most part, admit of relief by operation.

Painful moving or floating kidney, being only a mechanical disturbance, admits of relief only by mechanical means. Simple exploration and replacement through an incision in the loin would probably be found sufficient in the majority of cases for the cure of this condition,—the adhesion resulting serving to retain the organ in position. Stitching of the capsule to the parietes, or, as it is termed, nephrorraphy, is a somewhat serious, but still simple, undertaking. In eight cases in which it has been performed the patients all recovered and were relieved. There might still be cases where intense suffering was experienced, and where the other means had failed, which would suggest nephrectomy. Martin, of Berlin, had, in six cases, removed floating kidneys through the peritoneum, and four of these recovered.

Hydronephrosis should be first aspirated, then cut down upon and drained through the

* Terms, \$3 per annum. Published by the Medico-Legal Journal Association, New York.

loin, the cyst-wall being stitched to the parietes. Finally, should the fistula fail to close, the remains of the kidney might be removed through the loin.

In women these tumors had been often mistaken for ovarian tumors, and had been operated upon as such. Being movable, and not forming adhesions till late, some might advocate ventral nephrectomy for these cases before drainage; but such treatment would entail more risk than the method advocated. Abdominal nephrectomy for hydronephrosis will, however, show better results than nephrectomy generally.

Large isolated cysts of the kidney having no communication with the pelvis are rare. They should be aspirated and afterwards drained through the loin.

Hydatids of the kidney, also rare, have a tendency to discharge themselves through the pelvis. When forming tumors, they may generally be cured by aspiration or siphon tapping.

Pyonephrosis, when unilateral, falls under renal surgery. The double pyelitis, with suppuration and distention, which commonly resulted from stricture and enlarged prostate, the author said was inappropriately named "surgical kidney." He suggested the term *reflex pyelitis* as better expressing this condition. Reflex pyelitis, when one-sided, is due to some obstruction in the ureter, and then often gives rise to a large pyonephrosis. Other causes of unilateral pyonephrosis are calculus and strumous pyelitis. After speaking of the diagnosis, and stating that these tumors are more adherent and gave rise to more pain and constitutional disturbance than hydronephrosis, he said that nephrectomy for pyonephrosis had been performed twenty-eight times, and of these seventeen recovered and eleven died; but it was most worthy of notice that among these twenty-eight cases six had previously discharged their contents through a fistula in the loin, and all these recovered. Hence, he argued, it is better to drain a pyonephrosis before performing nephrectomy.

Neoplasms of the kidney can only be treated by nephrectomy, and if this be performed early there might be a good chance of permanent benefit. Generally they are too large to be removed except through the peritoneum, but of five cases removed through the loin, four recovered. Out of sixteen removed by ventral incision, ten died and six recovered.

Calculus of the kidney offers an excellent field for surgical interference, but the difficulty is to make sure of the diagnosis. Many cases of supposed calculus turn out to be strumous kidneys. Two cases were related in which the kidney was explored and even deeply punctured, but no ill result or rise of temperature followed, and the wounds healed primarily. Several cases of nephro-lithotomy were recorded in the Clinical Society's Trans-

actions, and two cases had been performed successfully at Guy's Hospital during the present year. When the kidney is much dilated and damaged it would be a question whether it might not be better to remove it.

After briefly alluding to *injuries to the kidney*, which, though not included under the title of the paper, might suggest nephrectomy, the author proceeded to speak of some details in operating. He recommended for the lumbar operation a combination of two incisions which he had employed as giving the most room,—viz., an oblique incision higher than the colotomy incision, within about half an inch of the last rib and parallel with it, and a vertical incision on the outer margin of the quadratus lumborum, extending from the upper edge of the last rib to the iliac crest. For the transperitoneal operation Langenbuch's incision external to the rectus muscle was to be preferred to the median incision, as it enables the operator better to reach the kidney through the outer layer of meso-colon.

In conclusion, he urged that antiseptic exploration of the kidney through the loin is a simple and not at all a dangerous operation, which may be undertaken without anxiety in any case where calculus is suspected; that it is generally wiser to tap and drain fluid tumors of the kidney before proceeding to remove the diseased organ; that when nephrectomy is decided upon, the extraperitoneal operation through the loin should always be chosen for any tumor it is possible to withdraw through the limited space at disposal; finally, if this course be adopted, the transperitoneal operation will be reserved for large solid tumors, and perhaps some floating kidneys.—*British Medical Journal*.

MISCELLANY.

THE NATIONAL RETAIL DRUGGISTS' ASSOCIATION.—A convention of the retail druggists was recently held in Washington, which resulted in the formation of a permanent organization known as the National Retail Druggists' Association, with the following officers:

President.—Henry Canning, of Boston.

Vice-Presidents.—N. W. Jennings, of Baltimore, and J. B. Bond, of Little Rock, Arkansas.

Secretary.—J. W. Colcord, of Lynn, Massachusetts.

The object of the Association, as embodied in a resolution offered by Professor Remington, of Philadelphia, is "to unite all retail druggists for the purpose of obtaining protection in their business interests from evils known to exist, and for mutual support and co-operation." The evils referred to are understood to be the patent-medicine business, and the general sale of nostrums as articles

of merchandise by grocers and others not dealing legitimately in medicines. When druggists and patent-medicine proprietors fall out, there is a probability that both the physician and the public will be benefited sooner or later.

THE MEDICAL NEWS; QUININE PILLS; AND THE HIGHER WALKS OF (SENSATIONAL) JOURNALISM.—*Gaillard's Journal* for September administers a well-deserved rebuke to the *Medical News* (published in this city) for its discourteous language towards its contemporaries, and its unwarranted aspersion of their motives, in a recent editorial contained in that periodical, and shows that the charges of weakness, cowardice, and venality have been thus far proven only against the management of the *Medical News* itself. We say, with Hamlet,—

"Let it work;
For 'tis the sport, to have the engineer
Hoist with his own petard."

THE CAMDEN COUNTY MEDICAL SOCIETY, having been invited to meet with the Philadelphia County Society, was present at a large and interesting meeting held at the hall of the College of Physicians, Philadelphia, October 10. The exercises consisted in the reading of a paper by Dr. Albert H. Smith on "Abdominal Palpation in Pregnancy," which was followed by an interesting discussion. After these exercises, a social reception was held by the Philadelphia Society, which was generally enjoyed by the large number present.

THE PATHOLOGICAL SOCIETY OF PHILADELPHIA held a semi-annual meeting, at which Dr. Carl Seiler read a paper on Phthisis and its Laryngeal Complications, which elicited a valuable discussion. This was followed by a very pleasant social reunion at the hall of the College of Physicians, on the 25th ult. The Society is now in a very flourishing condition.

NOTES AND QUERIES.

THE BALTIMORE MEDICAL COLLEGE.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—In opening the last number of your valuable journal (October 20), I am very much surprised to see that you have published from an anonymous correspondent such a partial statement of the medical colleges of this city, doing injustice to and misrepresenting the Baltimore Medical College. It seems unjust that you did not publish its plan and the names of the members of its Faculty, as you did for the other schools of the city. This school is misrepresented, because the assertion and intimations made in reference to it do not accord with the facts.

The Baltimore Medical College was organized over two years ago, with the avowed object of elevating the standard of medical education,—“not to make many doctors, but good and competent ones.” Its charter simply requires, among other things, that its teachers shall declare their belief in the Christian religion, as its projectors thought the sacredness of the medical profession required good men to promote its elevation.

A preliminary education as a prerequisite to enter the school, its extended sessions of seven and a half months each, and its special laboratory exercises during the session were

features intended to and doubtless have contributed to secure the object set forth,—namely, to afford students ample opportunity to become proficient in their studies.

No official notice has ever been given that the diplomas of this school were not recognized by the West Virginia Board of Health. On the contrary, several of its graduates are now successfully practising medicine in that State. As to the probabilities of the Illinois State Board of Health, it is only necessary to refer to its last (fifth) Annual Report, and compare the published requirements of this school with those of the other medical schools of Maryland, to satisfy any unprejudiced mind that its diplomas will be recognized by that Board.

Your correspondent most unjustly refers to a report, said to have been made at the introductory lecture of this session, that the “establishment of a pulpit is in contemplation.” No one uttered such a sentiment on that occasion, nor even thought of such a thing. The establishment of a hospital was mentioned, and since the opening of the present session hospital privileges have been obtained for the school in one of the most spacious hospitals in the city. The fact is, the Baltimore Medical College is exclusively a medical educational institution.

Your correspondent says, “During the first two sessions lectures were delivered to a class of men, women, and preachers.” During its two sessions it admitted both males and females; the latter sex have now been excluded, as a woman's medical college has been established in this city. As to preachers, only one pastor pursued the course of lectures during the two years, and graduated, he says, chiefly for the love of the science. He is still devoting his services to the pastorate in the church, and not practising medicine.

Your correspondent insinuates that the professors and lecturers in this college are unreliable, and not of sufficient reputation to command the confidence of the profession of this city. Now, Mr. Editor, will you please do the Baltimore Medical College the justice to publish, in connection with this communication, the names of the members of its Faculty (as you have already done for the other medical schools of this city), that your readers may judge of the character and fitness of these men to conduct a medical school? I hereby mail you copies of our announcement and lecture-card for that purpose.

Yours, truly,
W. R. MONROE, M.D., Dean,
249 Bolton Street, Baltimore.

[FACULTY OF THE BALTIMORE MEDICAL COLLEGE.—Harvey L. Byrd, A.M., M.D. (President), Obstetrics, and Diseases of Women and Children; W. Robert Monroe, M.D. (Dean), Materia Medica, Therapeutics, and Hygiene; Thomas Daugherty, A.M., M.D., Physiology; Glanville Rusk, M.D., Surgery; Charles G. Hill, M.D., Anatomy, and (Clinical) Insanity, and Nervous Diseases; Robert H. P. Ellis, M.D., Principles and Practice of Medicine; —, Professor of Chemistry; Lewis M. Eastman, M.D., Microscopy; F. W. Pearson, M.D., (Clinical) Diseases of the Chest and Throat; George P. Yost, M.D., (Clinical) Dermatology; J. H. Scarff, M.D., (Clinical) Gynecology; J. L. Dorksen, M.D., (Clinical) Diseases of the Eye and Ear; Thomas H. Parramore, D.D.S., (Clinical) Oral Surgery; James G. Linthicum, M.D., (Clinical) Obstetrics; Z. K. Wiley, M.D., Demonstrator of Anatomy.]

LETTER FROM DR. BYRD, OF THE BALTIMORE MEDICAL COLLEGE.

“*Magna est veritas et prævalet.*”

EDITOR OF THE MEDICAL TIMES:

Had not absolute falsehood been perpetrated in the notice of the above institution by your special correspondent in the last issue of the *Medical Times*, it would hardly have been necessary to take any notice at all of the illiberal and partisan statements it contained concerning the religious feature of the college, which he attempts to ridicule and to turn to the disadvantage of the institution. But as Christianity has proven “to the Jews a stumbling-block, and to (atheistic) Greeks foolishness,” for nearly nineteen centuries, and is clearly now “a thorn in the flesh” to many others, I will state, for the benefit of those readers of the *Times* who are unfamiliar with the facts in the case, that the charter granted to the college by the Legislature of Maryland requires that all its professors and teachers shall declare their belief in the Christian religion ere entering upon their respective duties in the same; and not that they “should likewise be professors of Christianity.” Women were admitted into the college, as he states, with the hope and expectation that most of them would prepare themselves for missionary work in the Orient or elsewhere, where Christian women physicians have done so much noble work in the evangelization of the heathen. But, as few applied for medical training with such an object in view, the project was abandoned. The statement he

makes about the West Virginia State Board of Health refusing to acknowledge the diploma of the Baltimore Medical College amounts simply to this, and nothing more,—viz.: one of the first graduates of the school, and when it was but little known, appeared before the Board, and, passing an excellent examination, paid his fee, and was licensed to pursue his profession, just as the graduates of other schools had, or ought to have, done before him.

Subsequent graduates of the Baltimore Medical College are pursuing their professions in that State without let or hindrance, so far as I know. The remarks he ventures to make regarding the Illinois Board of Health are entirely gratuitous, as no graduate of this school has ever presented a diploma before it, and I feel confident, from what I have learned of the gentlemen composing the Board, that they would not be likely to stultify themselves at the dictum of one whose animus is so obviously manifest as that of him who has assumed to speak for them in advance of a contingency which may never happen or come to pass. Clergymen of most of the Christian denominations have found from experience that they can listen to the lectures in Baltimore Medical College, and derive pleasure as well as profit in learning that the wisdom displayed in the structure and functions of the human body, and in the action of remedies upon it in disease, is in *perfect harmony* with the teaching of the lowly Nazarene; and a cordial invitation is extended to all such gentlemen as may desire to learn that scientific medicine can be taught without irreverent jests or sacrilegious innuendo or comparison, to call and listen to the teaching in the school as often as their clerical duties or their inclination may allow them to do so. It goes without the saying that a gentleman is privileged in this country to select his associates, professional and lay; and, in pursuing this course, I have found mine, here and elsewhere, among the *best and most* intelligent of the land. Such being the case, it could hardly be expected that I could be induced to mingle or continue an association with others of a different stamp, though it were to my *pecuniary interest* to do so; and this your correspondent and some of his *confrères* very well know and understand, though they should be indebted, to a very great degree, for the little notoriety they have reached, to labors of mine in the past. A few sentences more, and I will have done. The statement concerning the "pulpit" in the Baltimore Medical College is utterly and unqualifiedly false in every particular, and can be so proven by dozens of as respectable gentlemen and ladies as can be found anywhere. I send, with this paper, a copy of the circular of the Baltimore Medical College, which will show the names of fourteen professors and teachers who in every respect are regarded as the peers of any in this city by those in position to sit in judgment in such a matter. I am in position to make revelations which would not be flattering to your correspondent and some of his "professional" associates, but I forbear, as justification, and not retaliation, is the object of this paper, and especially as I feel quite confident that he is the *only* person in Baltimore who, without provocation of any sort, could have *conceived* and written *such* an article.

Very respectfully,

Your obedient servant,

HARVEY L. BYRD, M.D.,

President and Professor Baltimore Medical College,
Baltimore, Maryland.

127 NORTH ARLINGTON AVENUE,
BALTIMORE, October 23, 1883.

CELSUS ON HYDROPHOBIA,—A CORRECTION.

TO THE EDITOR OF THE MEDICAL TIMES:

DEAR SIR,—In requesting the publication of the accompanying letter, a few words may be needed. Some weeks ago an article on hydrophobia appeared in your columns containing a quotation alleged to be from Celsus. It appeared to my son, Dr. Louis W. Atlee, that Celsus had been treated with impropriety and entirely misrepresented. According to the author of that paper, Celsus recommends the forcible drowning of a hydrophobic patient, while the truth is that, while he does advise the throwing of the patient into the water in order to obtain the benefit of the sudden nervous shock, he most carefully tells us to give the patient a bath of warm oil after his ducking, lest harm may come of it.

My son wrote to the editor of the *Medical News* a letter correcting this misstatement (for so I would term it), and implies in this letter—most charitably, one would think—that the misstatement was caused by not consulting Celsus in the original. This supposition the author of the article referred to resents in rough terms in a recent number of the *Medical News*, and an editorial appendix to his communication endorses and upholds him in his views. My son is mentioned there by name in a discourteous tone and in intemperate language. To me, the denial of the correctness of the criticism only aggravates the literary offence.

The criticism was directed against the too prevalent habit of quoting an author at second-hand,—a fruitful source of error and injustice. For instance, we are told in the Holy Scriptures that "the fool saith in his heart, There is no God." Should some one who declares that we read therein, "There is no God," be excited, and roundly assert that he had read it in the original, and get others to back him, when reminded that he had not quoted the whole passage? Most certainly, the most charitable construction to put upon the error was that the writer had been led into making it by confiding in some one who had quoted Celsus, and had neglected himself to verify the citation. As we are wished by him, however, and also by the editor of the *News*, not to believe this, but to believe rather that Celsus was read by him in the original, and that such was his interpretation of the original passage, and as he is offended and the editor is aggrieved that any other belief can be held, another view must be taken, and what this view is any one of ordinary scholarship and of approved ethics can decide for himself. My son is not in this country at present, or he would need no one to act for him on this occasion. I will ask you to publish the accompanying letter, which I am sure will be read with pleasure by any one capable of judging in this matter. Although the reader will see that this communication is dated October 6, it was retained by the editor of the *Medical News* until the 23d, for reasons best known to himself.

Very respectfully yours,

WALTER F. ATLEE, M.D.

BALTIMORE, October 6, 1883.

DR. LOUIS W. ATLEE.

DEAR DOCTOR,—Although not personally acquainted, yet I hope you will excuse a professional brother in thanking you for your defence of the character of that old noble Roman, *princeps medicorum*, from the charge of cruelty in his treatment of the hydrophobic patient, as you have done in your recent paper in the *Philadelphia Medical News* of the 6th instant, under the heading "Celsus on the Treatment of Hydrophobia."

You administer a well-deserved rebuke to the common practice of quoting at second-hand without verifying,—a practice a little too frequent nowadays.

I had occasion to defend the character of Celsus from the charge made in a paper on "Anatomy Historically Considered," by Dr. H., of John's Hospital Union of this city, that "the old Roman was averse to making dissections of the human body as a means of advancing the science of medicine." By referring the gentleman to the original—Liber I., cap. i.—I convinced him of the mistake, and he acknowledged that he had quoted Celsus from a French translation, and he promised to correct the second edition of his paper.

To slander the character of a dead hero in medicine is, to me, as heinous as to mutilate his remains.

Again thanking you, I am, with much respect,

Your obedient servant,

JOHN R. QUINAN.

THE CHICAGO WIRE BEEF-SKEWER REDIVIVUS.

MR. EDITOR,—Dr. Miller is unnecessarily irritated concerning my paper on Chicago beef, and in his letter to the *Times* of October 20 he has fallen into three errors concerning it.

First, He infers that my knowledge of the barbs was obtained from a *retail* dealer, whilst his information came from a *wholesaler*. There are several wholesale dealers in this city, and the person to whom I referred is an extensive, well-known *wholesale butcher*, with three large establishments in this city, and an abattoir in Chicago with corresponding stock-yards, and he ships his supplies direct. I named him, not from any interest in himself or his business, nor did I say that *his* meat was superior to that of others dealing in Chicago beef, but simply because he courteously gave me a large number of the wire skewers for exhibition to the County Medical Society, after other parties had refused to let me have any through fear of their being employed adversely to their interest. "One good turn deserves another."

Second, The alleged extension of danger through the business cards of retailers being attached with the wire barbs to the large number of pieces into which the carcass is cut, is visionary; because the skewers are made in Chicago, *four* only are sent with each steer, and they are returned to the abattoirs, by two firms here at least, for further use. "Multiplication is vexation, division's twice as bad."

Third, The non-acquaintance of Dr. Miller with the clique of retail butchers to whom I referred as opposing the introduction of the beef into this city, does not militate against the fact, for, aside from the agitation noticed at the time in the public newspapers (and the same issue is now in

progress in other places), my information was obtained from three of these persons, who declared their intention to drive the Chicago product out of the market "by hook or by crook."

Finally, I dislike to destroy the fancied security thrown around the community by Dr. Miller and the wholesale firm he refers to as having discontinued the use of the barbs. Chicago people are enterprising, they care nothing for the brotherly love and philanthropy of quiet Philadelphia, the wire skewers admirably fulfil their intended purpose, they are not, as he says, "a thing of the past," but they are *still* used. I have seen several large shipments since Dr. Miller's letter appeared (the last one this morning), in three different wholesale houses, and I enclose two labels with barbs attached, obtained this morning at two of these places,—the third dealer hesitating about letting me have one, as he did before. My paper was written many weeks *after* the alleged swallowing of the barbed skewers, and *after* the supposed repudiation of them by the firm to which the doctor refers, and my object was simply to bring the excellent quality of the beef before the Philadelphia County Medical Society when the question of food and dietetics was being discussed. If I am wrong in my opinion that the skewers are harmless and cannot be swallowed by ordinary mortals, then the consolation remains that an unhopd-for new specialty in medicine has been found,—that of "EXPERT in the extraction of *Chicago barbed-wire beef-skewers*."

I am, sir, with distinguished consideration,
WILLIAM R. D. BLACKWOOD, M.D.,
Neurologist to Presbyterian Hospital, and
Physician to St. Mary's Hospital.

October 27, 1883.

DEATH OF SURGEON-GENERAL CRANE, U.S.A.

The death of Charles H. Crane, M.D., Brigadier-General and Surgeon-General, United States Army, occurred at Washington, October 10, after a brief illness. Until two days before his death he was not considered seriously ill. He had been suffering with an abscess under the tongue, which led to perforation of, and fatal hemorrhage from, the lingual artery. He was graduated in arts at Yale in 1844, and at Harvard Medical Department in 1847. He went at once into the service, and, rapidly rising (being promoted for meritorious service during the war of the Rebellion), he was made colonel and Assistant Surgeon-General in 1866, and brigadier-general and Surgeon-General, July 3, 1882, succeeding Surgeon-General Barnes. He died in the fifty-ninth year of his age. The last honors were paid at Shelton Island, New York, where his remains were interred. By a general order, dated October 10, the Secretary of War pays a tribute to the personal worth and distinguished services of General Crane. The officers of the Medical Department will wear the usual badge of mourning for six months.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM OCTOBER 6 TO OCTOBER 27, 1883.

HAMMOND, JOHN F., COLONEL AND SURGEON.—Leave of absence on surgeon's certificate of disability granted April 2, 1883, extended six months on surgeon's certificate of disability. Paragraph 7, S. O. 231, A. G. O., October 8, 1883.

SWIFT, EBENEZER, LIEUTENANT-COLONEL AND ASSISTANT MEDICAL PURVEYOR.—Under the provisions of Section 1 of the act of Congress approved June 30, 1882, is, by operation of law, this day retired from active service, and will proceed to his home. Paragraph 4, S. O. 231, A. G. O., October 8, 1883.

BACHE, DALLAS, MAJOR AND SURGEON.—Assigned to duty at Willet's Point, New York. Paragraph 1, S. O. 238, A. G. O., October 18, 1883.

HARTSUFF, ALBERT, MAJOR AND SURGEON.—Granted leave of absence for fifteen days. Paragraph 2, S. O. 205, Department of the Missouri, October 6, 1883.

HUNTINGTON, DAVID L., MAJOR AND SURGEON.—By direction of the President, will, until further orders, take charge of the office of the Surgeon-General of the Army, and perform the duties pertaining thereto. Paragraph 3, S. O. 234, A. G. O., October 11, 1883.

MEACHAM, FRANK, MAJOR AND SURGEON.—Assigned to duty at Fort Douglas, Utah. Paragraph 3, S. O. 109, Department of the Platte, October 6, 1883.

STERNBERG, GEORGE M., MAJOR AND SURGEON.—Granted leave of absence for one month, to date from October 6, 1883, with permission to go beyond the limits of the Department, and to apply for extension of one month. Paragraph 3, S. O. 134, Department of California, October 4, 1883.

TAYLOR, MORSE K., MAJOR AND SURGEON.—Assigned to duty at Fort Sill, I. T. Paragraph 4, S. O. 210, Department of the Missouri, October 13, 1883.

CRONKHITE, H. M., CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty at Fort D. A. Russell, Wyoming. Paragraph 3, S. O. 109, Department of the Platte, October 6, 1883.

HEIZMANN, CHARLES L., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for six months, with permission to go beyond sea. Paragraph 3, S. O. 235, A. G. O., October 15, 1883.

WEISEL, DANIEL, CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty at Fort Fred Steele, Wyoming. Paragraph 3, S. O. 109, Department of the Platte, October 6, 1883.

ARTHUR, W. H., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to duty at Fort Douglas, Utah. Paragraph 3, S. O. 109, Department of the Platte, October 6, 1883.

STRONG, NORTON, FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to duty at Fort Washakie, Wyoming. Paragraph 3, S. O. 109, Department of the Platte, October 6, 1883.

MOORE, JOHN, LIEUTENANT-COLONEL AND ASSISTANT MEDICAL PURVEYOR.—To be relieved from duty as Medical Director, Headquarters Department of the Columbia, to proceed to San Francisco, California, and assume charge of the medical purveying depot in that city. Paragraph 10, S. O. 243, A. G. O., October 24, 1883.

HORTON, S. M., MAJOR AND SURGEON.—Leave of absence for one month, with permission to apply for an extension of three months. Paragraph 6, S. O. 216, Department of the Missouri, October 20, 1883.

WOLVERTON, WILLIAM D., MAJOR AND SURGEON.—Granted leave of absence for one month. Paragraph 6, S. O. 201, Department of the East, October 24, 1883.

BARNETT, RICHARDS, CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty at Columbus Barracks, Columbus, Ohio. Paragraph 1, S. O. 240, A. G. O., October 20, 1883.

MAUS, LOUIS M., CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty at Fort A. Lincoln, D. T. Paragraph 4, S. O. 180, Department of Dakota, October 15, 1883.

MERRILL, J. C., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for one month. Paragraph 7, S. O. 201, Department of the East, October 24, 1883.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY FROM OCTOBER 20 TO OCTOBER 27, 1883.

Medical Director W. T. HORD and Medical Inspector C. J. CLEBORNE ordered to the U.S. steam-ship "Hartford," at Panama, on duty connected with a court-martial.

Medical Inspector A. C. GORGAS detached from the Naval Hospital, Chelsea, Massachusetts, November 10, and ordered to the Naval Hospital, Mare Island, California.

Medical Director J. M. BROWNE ordered as member of the National Board of Health.

P. A. Surgeon A. C. HEFFINGER ordered to temporary duty at Navy-Yard, Portsmouth, New Hampshire.

P. A. Surgeon ROBERT WHITING granted leave of absence for three months.

The orders of Surgeon W. J. SIMON and P. A. Surgeon M. H. CRAWFORD in last week's report should read U.S. steam-ship "Shenandoah," instead of U.S. steam-ship "Trenton."

Surgeon W. K. VAN REYFEN detached from the Naval Hospital, New York, and ordered to the U.S. steam-ship "Powhatan."

Surgeon H. M. WELLS detached from the Naval Laboratory, New York, and ordered to the Naval Hospital, New York.

Medical Inspector A. C. GORGAS's orders modified so that he will be detached from the Naval Hospital, Chelsea, Massachusetts, on December 10, instead of November 10.

PHILADELPHIA MEDICAL TIMES.

PHILADELPHIA, NOVEMBER 17, 1883.

ORIGINAL LECTURES.

CLINICAL LECTURE ON VARICELLA.

Delivered at the Hospital of the University of Pennsylvania

BY LOUIS STARR, M.D.,

Chief of the Clinic for Diseases of Children.

GENTLEMEN,—The child before you is a little more than six years old. She has been under observation about a year, and during this time has enjoyed perfect health. Two days ago she awoke quite as well as usual, but as the day wore on she grew pale, did not take her accustomed interest in play, and in the afternoon exhibited a desire to sit quietly by the fire, thus showing that she was both languid and chilly. She refused her supper entirely, and while she was being undressed for bed an increased heat of skin was noticed. She passed a restless, feverish night.

When I saw her in bed, at noon yesterday, her face was somewhat flushed and listless in expression, and she complained of slight headache. Her tongue was lightly frosted; there was increased thirst, and little or no appetite; there had been no action of the bowels for forty-eight hours, and the morning urine was high-colored and loaded with lithates. The axillary temperature was 100° F., and the pulse counted 110 beats per minute. The lungs were found, upon examination, to be perfectly healthy, and, beyond moderate congestion, the pharynx presented no abnormal appearance. However, when she was stripped, a papular eruption was observed, irregularly scattered over the surface of the chest, abdomen, and back. These papules were isolated, the intervening skin being sound; they were about the shape and size of a split-pea, deep red in color, quite yielding and soft to the touch, and two or three of those situated on the chest showed, upon their summits, a tendency to the formation of vesicles. Further, the eruption, while most marked upon, was not confined to the trunk, for several papules were to be seen on the face, and a few also on the arms and legs.

During the afternoon there was little or no increase in the fever, and sleep was

much more quiet and restful than it had been on the preceding night.

As you see the patient this morning, you notice that, except some pallor and a slightly worn look, there is very little deviation from the normal facial expression. The skin feels moist to the hand, the thermometer indicates an axillary temperature below 99° , and the pulse, even under the excitement of coming before you, is only about 100 per minute. The tongue, you observe, is beginning to clean; there is no thirst, the appetite is returning, the bowels have been moved, and the urine has lost its febrile characters. There has been then, on this which is only the third day of the disease, a marked subsidence of the constitutional symptoms.

Let us next study the eruption. You will notice first that, while most abundant upon the trunk, it is distributed over the whole body, the scalp, even, not being exempt. Upon the face, scalp, and limbs it is mixed in character, there being in these positions both papules, having the features already described, and vesicles; on the other hand, all the papules yesterday observed upon the trunk have undergone conversion into vesicles. These vesicles are transparent, semi-spheroidal in shape, two or three lines in diameter, and cover the whole, or almost the whole, area of the former papules, in the first instance rising sharply defined from the normal skin, in the second being surrounded by a red areola about a line in width. There are two other points of interest, namely: several of the vesicles upon the chest have lost their transparency and are becoming opalescent,—a change due to the transformation of the serum into pus,—and here, upon the right buttock, is a pustule which shows a depression in its centre, or, in other words, is umbilicated,—an appearance depending on the commencement of desiccation.

To sum up the more important features of this clinical history, we have in the midst of health certain symptoms developed, namely: languor, chilliness, headache, loss of appetite, increased thirst, and moderate fever,—prodromes common to the eruptive fevers as a class; in less than twenty-four hours after their onset an eruption of soft red papules appears upon the trunk and rapidly extends over the whole surface of the body; not more than

twelve hours later these begin to be capped with vesicles, and at the end of another twelve hours nearly all of them are converted into vesicles and a few even into pustules; and, finally, at the present period of the disease, the beginning of the third day, there is a marked improvement in the general symptoms. Now, the only fever of childhood following the course and having the peculiar eruptive characters we have studied is varicella, or chicken-pox.

Since this case will have lost its distinguishing features before our next meeting, let me briefly sketch its probable future course, so that you may carry away a complete picture of the disease. Recall for a moment that the general symptoms are rapidly disappearing, that the majority of the papules have become vesicles, that some of the latter are becoming pustules and several even beginning to desiccate. By to-morrow (the fourth day) there will be no evidence of constitutional disturbance, except the moderate weakness which follows every trifling acute illness: the pulse may be feeble, but its frequency will be normal; the tongue will be clean, and the appetite good. All of the remaining papules will have been converted into vesicles, these again into yellowish pustules, and the process of desiccation will be fully established; then the pustules which have not been torn by the child's efforts to relieve the itching—for itching is often a prominent symptom—will show a shrunken appearance at their edges, or sometimes a little yellowish crust at their centres, producing a central depression or umbilication. The drying process, commonly proceeding from the circumference to the centre, will progress rapidly, so that by the sixth day it will be completed and all the pustules converted into thin, light-brown scabs. On the eighth or ninth day these will fall off and leave merely faint red, not depressed, and rapidly disappearing spots. Perhaps, though, if several of the vesicles have been unusually large and deep, and especially if accidentally broken by scratching, a scar, resembling somewhat the pit following a variolous pustule, will be left. Such pits you will usually find on the forehead or face, and it is very rare for more than one or two to be seen in a given case. By the time the crusts have fallen off the child will have, in great part, regained her strength, and with ordinary care there will be no drawback to the return to perfect

health. Varicella has no sequelæ, unless we may so class the occasional attacks of bronchial catarrh, or, rarer still, of pneumonia, produced by careless exposure to cold or wet during the period of eruption or convalescence.

Scarlet fever and measles, the two most common eruptive fevers of childhood, present so few points of similarity to varicella, and so many of dissimilarity, that it is impossible to confuse them when the least thought is exercised. The eruption of varicella in the papular stage might possibly be mistaken for that of measles, but you must remember the course of the two diseases. In measles there is a period of incubation extending over four days, and characterized by severe catarrh of the conjunctivæ and of the nasal and bronchial mucous membranes, as well as by a peculiar rose-colored papulation of the roof of the mouth, soft palate, and uvula; in chicken-pox, on the other hand, the stage of invasion occupies a period of from twelve to eighteen hours, and is attended only by symptoms common to all febrile diseases. Again, the rash in measles appears first upon the skin in front of and behind the ears, instead of on the chest, as is the case with the varicellous rash; then, the papules of the former disease are smaller, firmer to the touch, and deeper red than those of the latter, and they have, too, a tendency to arrange themselves into irregular clusters, somewhat suggestive of cressets. When the varicellous papules begin to be converted into vesicles,—an early occurrence, as you know,—all doubt as to the existence of measles is of course at once set at rest.

There is one disease, however, which presents some superficial features of resemblance to the affection in question, and concerning which it is most important that an early and accurate diagnosis should be made. I refer to variola. The surface-lesion of variola begins as a crop of papules, which pass next into vesicles, next into pustules, and then desiccate with the formation of crusts, which after a time drop off, leaving discolored blotches. Just so far the resemblance to chicken-pox goes. What, then, are the distinctive points? First, the course of variola is peculiar, and very different from varicella, being divided into a series of well-defined stages, each about three days in duration; second, it is marked by two pyrexial periods,—a fever

of invasion and a fever of suppuration or maturation; and third, the eruption, while passing through the same changes, possesses well-marked differences.

The stage of invasion lasts three days, and is marked by bilious vomiting or convulsions, high fever, and severe pain in the head, back, and limbs. Some time on the third day the eruption appears in the form of small, dark-red maculæ, which are soon converted into papules. These are only one-third to two-thirds of a line in diameter, and feel to the fingers like small grains of shot embedded beneath the skin. They are first noticed on the forehead and about the angles of the mouth, and thence extend to the rest of the face, to the neck, trunk, limbs, feet, and hands. With their appearance the fever subsides. They grow somewhat larger until the end of the fifth or beginning of the sixth day, when they become converted into pointed vesicles, this conversion taking place in the order of appearance of the papules: they occupy at first only the summits of the papules, but gradually grow larger until they cover a greater surface than that originally occupied by the papules, become flattened, depressed in the centre or umbilicated, and surmounted by a red areola varying in width. The contents of the vesicles now slowly become transformed into pus, and by the eighth or ninth day they are all converted into pustules; during this transformation the pocks become distended and the umbilication is lost. Coincidentally, too, the secondary fever, the fever of suppuration, sets in. About the twelfth day desiccation begins, and between the fifteenth and nineteenth the brown crusts begin to fall off. The desquamation leaves the surface in different conditions, but usually the ultimate result is the formation of little pits or depressed cicatrices which remain during life.

The eruption of variola may be found on all the visible mucous membranes, as well as upon the skin; the mucous surface first becomes injected, then dotted over the red area a number of papule-like elevations appear; these, after the second day, are converted into white, circular, and umbilicated pseudo-membranous points, which remain four or five days and fall off, leaving a shallow erosion, which heals without the formation of a cicatrix.

With variola, then, varicella stands contrasted by its brief invasion period, the

short duration of its initial fever, the absence of a secondary pyrexia, the difference in the position at which the eruption first appears, the larger size and the softness of the papules, the many minor points of difference in the eruption that have been mentioned, and especially the rapid transition of its phases.

There are several features of variola which are usually mentioned as important distinctions between it and chicken-pox, but which are of little or no diagnostic value. The mistake has arisen from the supposed fact that certain symptoms—the appearance of the eruption on the scalp, the presence of the eruption on visible mucous membranes, the umbilication of the vesicles, and the pitting—are confined to the former disease. Such is by no means the rule; for you will often find in varicella the eruption upon the scalp, as is the case with this patient. So, too, although it is not present in this instance, we see in a majority of cases a varying number of pseudo-membranous points upon the mucous membrane of the cheeks and palate, which differ only from those of variola in being larger and more yellowish in color. Again, as I have pointed out to you to-day, the vesicles may, and frequently do, present an umbilicated appearance, and finally, under certain conditions, slight pitting may follow. The umbilication only occurs in those vesicles which begin to desiccate at their centres, and on close inspection you will be able to detect a minute crust in these positions. Both the cause and appearance differ, therefore, from the variolous umbilication, but the likeness is sufficiently close to be a source of confusion. The pits left by the two diseases are very like, though I have usually found those of varicella broader, shallower, and smoother than those of variola.

Let these points, then, be discarded in forming an opinion, and base the diagnosis upon the well-marked differences in the eruption and in the course of the two diseases.

Varicella is one of the least severe of the diseases of childhood, and demands very simple treatment. Ordinarily the child should be confined to bed until desiccation is completed, and to one room until the crusts have fallen off, and the strength has returned. Sometimes, when the case is very mild, it will be sufficient to keep the patient in one room until convalescence is established; this room must

always be well warmed (72° F.) and ventilated. After desquamation the patient must be taken into the open air in suitable weather, properly clad. While the fever and thirst continue, the diet must consist of milk guarded by lime-water, and plenty of water should be allowed; afterwards, the ordinary articles of food may be gradually added as the appetite returns.

In the way of medicines all the indications will be fulfilled by a simple febrifuge, such as liquor potassii citratis or "effervescent draught," an occasional dose of magnesia or other saline laxative, as demanded by the condition of the bowels, some bland ointment, as ung. aquæ rosæ or ung. zinci oxidi, to allay the itching, and, after the fever has subsided, a tonic, —elix. cinchon. ferrat., for example,—to improve the appetite and build up the general strength.

ORIGINAL COMMUNICATIONS.

REPORT ON THE PROGRESS OF GENERAL PATHOLOGY AND CLINICAL MEDICINE.

BY JAMES C. WILSON, M.D.

ICTERUS NEONATORUM.

DR. FREDERICK P. HENRY (*Archives of Medicine*, October, 1883) makes public the result of his investigations in the pathology of this affection. He seeks to determine the question of the mechanical (hepatogenic) or chemical (hæmatogenic) source of the cutaneous pigmentation. He points out that to produce experimentally the first of these two forms of icterus, it would be necessary to increase the bile-pressure *absolutely* by ligation of the hepatic or common bile-duct, or to increase it *relatively* by cutting off a portion of the portal blood-supply.

Now, this latter experiment is performed in the case of every human being by ligation of the umbilical cord. The portal blood-pressure is suddenly and markedly diminished; abnormal conditions of osmosis are established, and when jaundice ensues it is only necessary to prove that the number of the pigment-carriers, *i.e.*, the red blood-cells, has not been reduced, in order to settle the question of the mechanical origin of icterus neonatorum. This he has done by counting the blood-cells in new-born children.

Of the five cases in which this research was carried on, four only have a direct bearing upon the question in hand. These I reproduce in the brief notes of the author of the paper, partly for the sake of making clear his views, partly for their intrinsic value as a contribution to the general knowledge of the blood in new-born children, in whom the blood-cells have not hitherto been made the subject of systematic study.

Case I.—October 19, 1881. Alice K., born at 8 A.M. Count made at 10.30 A.M. The child was of average size, and not cyanosed. Labor had been natural and easy. No symptoms of suspended animation. Child crying lustily when born. Weight, eight and a quarter pounds. The blood was obtained by puncture of the great toe, and was venous-looking. (The average number of red blood-cells per cubic millimetre is, in the adult, at least 5,000,000.)

Number of red cells per cubic mm., 6,410,000.

No white cells in specimen examined.

October 20, 10.30 A.M. Second count in the same case. Child thriving.

Number of red cells per cubic mm., 5,810,000.

October 22. Third count. Child doing well; no appearance of jaundice.

Number of red cells per cubic mm., 5,680,000.

Case II.—John G., born October 20, at 12 (mid-day). Labor easy and natural. Child not asphyxiated; weight, eight pounds. Count No. 1 made at 11 A.M., October 21.

Number red cells per cubic mm., 5,925,000.

This count corresponds closely with count No. 2 in Case No. I, which was made about the same time after birth.

October 23. Count No. 2.

Number red cells per cubic mm., 5,520,000.

Faint yellowish tint of skin.

October 25. Count No. 3.

Number red cells per cubic mm., 4,870,000.

Child deeply jaundiced.

The third case, in which only a single count was made, has no special relation to the subject.

Case IV.—William S., born November 6, 5 A.M.; weight, six and a half pounds.

November 7. Count No. 1.

Number red cells per cubic mm., 4,520,000.

Proportion of white cells to red, 1 to 904.

November 8, 11 A.M. Count No. 2.

Number red cells per cubic mm., 5,335,000.

Proportion of white cells to red, 1 to 711.

Child slightly yellow.

Case V.—Sela F., female, born November 17, 8.15 A.M.; weight, seven pounds; labor rapid and natural; child healthy-looking.

November 19, 10.30 A.M. Count No. 1.
 Number red cells per cubic mm., 5,185,000.
 Proportion of white cells to red, 1 to 350.
 November 21, 4 P.M. Count No. 2.
 Number red cells per cubic mm., 5,495,000.
 Proportion of white cells to red, 1 to 628.
 Slight icteric hue of skin.

If icterus neonatorum were of hæmatogenic origin, in the sense that the coloring-matter of the blood is set free by a rapid disintegration of the corpuscular elements of this tissue, we would expect to find some constant ratio between the intensity of the discoloration and the diminution of the red blood-cells. This Dr. Henry's cases do not establish. It is true that in Case II., the only one in which there was marked jaundice, this condition coincided with a rapid and great diminution of red cells; but it is also true that in Case I. there was a very decided loss in red cells without the occurrence of jaundice, and that in Cases IV. and V. with a slight degree of icterus there was an actual increase in the number of red cells.

The author regards these facts as warranting the conclusion that icterus neonatorum is of mechanical or hepatogenic origin.

To the questions, Why does it not invariably occur, since the umbilical vein is ligatured in all new-born infants? and why is it more frequently met with in delicate children than in the robust? Dr. Henry makes this reply:

The degree of immediate interference with the portal circulation produced by ligature of the umbilical cord depends both upon the anastomoses of the umbilical vein with the veins of the abdominal wall, and upon the vigor of the cardiac contractions. Where there is free anastomosis and a vigorous heart, the intravascular blood-pressure in the hepatic lobules may be maintained to such an extent as to prevent the resorption of bile, and *vice versa*.

It is understood that the foregoing observations have reference to icterus neonatorum, properly so called, and do not apply to cases of jaundice by obstruction.

The paper is of importance as shedding upon a vexed question of pathology the light of actual experimental observation, where hitherto the facts were much obscured by surmise and conjecture. Further work in this spirit is needed to clear up the subject.

THE INFLUENCE OF IODOFORM UPON THE DEVELOPMENT OF GIANT CELLS.

Dr. Emil Marchand (*Virchow's Archiv*, September, 1883), in the course of a series of studies conducted with the purpose of determining the origin of giant cells around foreign bodies, was led to employ iodoform with the view of controlling suppuration in the wounds of the animals subjected to experiment. Strenuous antiseptic precautions with carbolic acid having failed, iodoform was dusted freely into incisions made for the introduction of the foreign substances, which were then closed by sutures. The result was not that which had been looked for. A certain amount of pus-formation occurred, and in some places it was even more abundant than by the former method of operation. At the same time, however, the interesting observation was made that the microscopic appearances at many points were different when iodoform was used from those where the wounds had been treated by carbolic acid. The development of giant cells was retarded to such an extent that in one case it was only after thirty days had elapsed, at a time when iodoform was neither macroscopically nor microscopically to be detected in the tissues, that they were found around the foreign substances (silk threads); whereas, in the wounds not treated by iodoform, giant cells were developed at an early period and in great abundance. The author concludes from these observations that iodoform, in wounds in which the conditions necessary to the development of multinuclear and giant cells are present, is capable of hindering such cell-formation. The favorable influence of iodoform upon the development and course of scrofulous and tubercular granulation-tissue, recognized by most surgeons, has found in these facts a histological explanation. The large-celled, fungous character of such surfaces, in some way altered by the action of iodoform, is brought into the condition of normal granulation-tissue.

The author, without reaching a definite conclusion as to the histogenesis of giant cells, regards it as highly probable that they are developed from fixed connective-tissue cells, and not from extravasated white blood-cells.

RENAL CIRCULATION DURING FEVER.

Dr. Walter Mendelson (*American Journal of the Medical Sciences*, October, 1883)

communicates an account of an experimental research into this subject, conducted at the Pathological Institute of the University of Leipsic. To this paper was awarded the Cartwright Prize for 1883. The research was carried on under the auspices of Professor Cohnheim. The instrument used was invented by C. S. Roy, and used by him previously in studying the functions of the spleen, and, in association with Cohnheim, the circulation in the kidneys. It is called the Oncometer, or "bulk-measurer," and can, it is said, be applied to the kidney without interfering with the functions of the organ, and affords an exact index to the condition of its circulation.

The mechanical principle of the action of this instrument depends upon the expansion and contraction of the organ under investigation (due to variations in the volume of blood circulating in it), causing corresponding variations in the amount of some surrounding confined liquid, as oil. By means of a suitable mechanical appliance called the Oncograph, these variations in bulk, transmitted to the surrounding liquid, are graphically recorded upon the revolving drum of Ludwig's Kymographion.

The dogs which were the subject of the experiments were rendered insensible to pain and immobile by destruction of the thalami optici. It was found that the puncture of one thalamus was sufficient for practical purposes, and that the temperature rose more rapidly and higher than when both thalami were destroyed. Fever was induced by the intravenous injection of pepsin, or by keeping the animals enclosed in a warm-air chamber.

In all, the experiments performed with a view of determining the facts regarding changes in the renal circulation during fever numbered ten (seven with thermic fever, three with pepsin fever), and every experiment, without a single exception, showed during fever a progressive diminution in the volume of the kidney.

Several control experiments were made to settle the question as to the influence of the irritation of the manipulation of the kidney, or the presence of the oncometer, in bringing about contraction of the renal vessels. In these observations the instrument was applied to the kidney and left on for several hours, the bodily temperature being normal. The kidney retained its

original volume as long as the animal remained afebrile, but began to contract upon the superinduction of fever.

The fact that the kidney contains no contractile elements except the blood-vessels makes it evident that changes in the volume of this organ must depend upon changes in the amount of blood contained in its blood-vessels.

Further investigations, to determine the central or peripheral nature of the irritations acting on the renal capillaries, led to the conclusion that "the decrease in the bulk of the kidney during fever is due to a contraction of its vessels, which, in all probability, is the result of a stimulus conveyed to them from the central nervous system; the stimulus being the consequence of irritation of the central vasomotor centres by the abnormally hot blood circulating through them during fever."

The results of these investigations are wholly at variance with the prevalent hypothesis concerning the condition of the renal circulation during fever. The opinion has been heretofore universally held that this condition was that of congestion. It was based upon the general condition of the circulation as observed in more accessible parts of the body, upon the changes occurring in the urine, and upon the state of the organs in post-mortem examination. Instead of being swollen from the distention of its vessels with blood, the kidney of fever is small, shrunken, and in a state of extreme anæmia. The diminution in the amount of urine excreted is due not only to increased loss of water by the lungs and skin, but also to diminished renal circulation. The albuminuria so common in high fevers is readily accounted for by the effect of the local anæmia upon the epithelium of the glomerules, which, insufficiently supplied with arterial blood, becomes so impaired in function as to be permeable to albumen. Repetition of these experiments will be looked for with interest. In the event of these results proving constant, a revision of the whole subject of the renal pathology of the acute febrile diseases will become necessary.

THE TRI-STATE MEDICAL SOCIETY changed its name at its last meeting, and is hereafter to be known as the Mississippi Valley Medical Society.

CONCERNING ARROW-WOUNDS.

BY W. THORNTON PARKER, M.D.

ALTHOUGH many of our Indian tribes are at present armed with the most perfect modern breech-loading rifles, the arrow is still the favorite weapon of many Indian warriors. Swift, silent, accurate, and deadly, it possesses for their purposes many advantages either for the chase or for warfare.

The arrow, one of the oldest of weapons, seems to have nearly outlived its usefulness, and no doubt will soon exist only in museums or in the gentle sport of archery, but at present it is an implement of Indian warfare still worthy of consideration. By our soldiers stationed on the frontier, and inured to constant Indian forays, it has ever been regarded with the greatest aversion, the most dreaded of all missiles to which they are exposed. A single scratch from one of these terrible implements is more to be feared than many a bullet-wound. In one of our frontier hospitals a soldier died in great suffering from what seemed to be a very superficial flesh-wound across the chest, made by an arrow in a skirmish with Indians. The arrow was left on the field, and so it was quite impossible to determine the nature of the poison; but that he was the victim of a poisoned arrow admits of little doubt. The supposition that the Indian shoots his arrows carelessly and wastefully is erroneous. It is possible for the expert marksman to discharge arrows rapidly, but it requires too much time and labor to make a perfect arrow; and, even if the Indian were not inclined to laziness, materials for arrow-making are usually too scarce to allow of much waste of such valuable ammunition in action. The arrow can be shot with as much precision as our best modern revolvers, and at one hundred yards is a deadly weapon. The arrow flies with great swiftness, and has great penetrating power. Several specimens in the Army Medical Museum show how deeply an arrow-head can perforate bone. A soldier rode into Fort Cummings, New Mexico, chased by Apaches. He had received one or two wounds, from the effects of which he died, and in the tree of the saddle he rode upon, an arrow-head was so firmly embedded as to defy removal.

The arrow of the American Indian is indeed skilfully prepared, light, straight, and

strong. The shaft contains carefully-made grooves, to allow the blood to escape easily. Each tribe, and even each warrior, has easily-recognized devices on the shaft, so that they are able to determine from whom the arrow came. To secure the necessary feathering requires skilful fingers; but perhaps the best work on the arrow is shown in the attachment of the head to the shaft. After carefully drying and straightening the shaft, a slot is made into which the arrow-head is carefully fitted and bound with wet sinew. The drying of the fibres contracts until the arrow-head is secure.

Many of the best arrow-heads are manufactured in the Eastern States and sold to Indians through the traders, or even issued by Indian agents; but they are mostly made from scraps of iron hooping, of flint-stone, bone, glass, wood, etc. Not long ago, many agricultural implements, presented to the Indians by admiring Eastern philanthropists, furnished admirable opportunities for the manufacture of countless quiverfuls of arrows.

The attachment of the arrow-head, although secure while dry, rapidly loosens when wet, and it is on this account that it is almost impossible to remove shaft and head from a wound. The head is almost certain to become detached and remain hidden or firmly embedded in the wound.

But if the Indian has shown considerable skill in the manufacture of the arrow, he also possesses remarkable surgical ability in removing an arrow from the wound.

The removal is effected by taking a willow stick and carefully splitting it and rubbing it as smooth as possible; then the pith is carefully cleaned out, and the ends rounded to present as little obstacle as possible in following the wound-track. One stick is introduced very carefully to reach and cover the uppermost fang of the head, and the other to cover the lower fang, and when both are properly adjusted the outer ends are bound to the shaft of the arrow, and all are carefully and slowly withdrawn. When it is possible to push the arrow through until the head is exposed and cut off, it should be done; the shaft can then be drawn backward easily. No traction should ever be made with the shaft unless the head has been removed; for the least effort in this direction is sure to loosen it and leave the head in the wound, thereby adding increased dangers to a wound already serious.

Much difference of opinion seems to exist concerning the poisoning of arrows, and many deny that the American Indian intentionally poisons his arrows; nevertheless it is generally admitted that most of our Indian tribes practise the art of arrow-poisoning and show considerable devilish ingenuity in doing so. In the first place, we must consider that all tribes hold more or less secret all that relates to the education of the warrior, and it is not surprising that the mysteries of arrow-poisoning are not so lightly valued as to enable any one to become familiar with the process. It is very naturally a secret which few warriors would care to communicate. Many substances are used, and undoubtedly some methods elaborate in disgusting details fail to make the arrow as poisonous as some of the simpler methods seem to do. Some rely upon juices pressed from poisonous plants, into which not only the heads but the shafts also are dipped, and others use animal substances and fluids, like rotten flesh and putrid blood, even reserving portions of dead enemies for this purpose, although this last method is very rare indeed. Some use a combination,—for instance, a liver and mashed serpents' heads,—but generally each warrior or family have their own secret method of poisoning, as well as of preparing the "medicine" to make the arrow deadly.

Perhaps the commonest method and least secret of all is to take a beef's liver and stick it full of arrows, like pins in a pin-cushion, and leave it in the sun until the animal mass has rotted away. M. Hoffman* has stated regarding "poisoned arrows," at a recent séance of the Société d'Anthropologie, that "the Apaches [Cayoteres, *sic*] bruise up the heads of rattlesnakes with fragments of deer's liver, allow the mass to become putrid, then dip the arrow-points, and allow them to dry slowly." He also mentions the use of poisonous plants, *i.e.*, the "Spanish bayonet," also red ants pounded together, and other methods.

Besides being more elaborately decorated, if not certainly poisoned, the war arrow differs in make from the plainer hunting arrow. The head of the war arrow is shorter and broader than that of the hunting arrow, and is attached to the shaft at right angles with the slot which fits the bow-

string, the object of this being to allow the arrow in flight more readily to pass between the human ribs, while the head of the hunting arrow, which is long and narrow, is attached perpendicularly to the slot, to allow it to pass readily between the ribs of the running buffalo.

These arrows are also used for conveying fire, either in considerable masses to set fire to hay or to inflammable buildings, or as signals at night. The writer was once with an expedition crossing the plains, and at Cimarron Crossing the whole command was surrounded by large numbers of Indians, who during the night seemed to be in communication with each other from one side of the river to the other by means of fire-arrows.

All these details which I have mentioned show how skilfully the Indian arrow is made, and also what a formidable weapon it must be in the hands of experienced and crafty marksmen.

The following remarkable case illustrates the fact that, while the simplest arrow-wounds may prove mortal, recovery can follow a wound which from its very nature seemed certainly to have no other than a fatal result in prospect:

While passing through the little town of Trinidad, New Mexico, some years ago, I was called to see a man who had received a severe and apparently desperate arrow-wound through the right chest in a skirmish with Indians a day or two before. The arrow had penetrated quite through the right lung. Either the arrow-head had passed quite through between the posterior ribs in the first instance, or had nearly done so, and had finally been pushed out (probably by some one familiar with arrow-wounds). At any rate, enough had passed through to allow of detaching the head from the shaft, and then the shaft itself had been withdrawn the entire length of the wound.

Some hemorrhage had followed this rough surgery, but how much I was unable to ascertain, and the shock, which had at first prostrated the patient, had been recovered from. I found the patient, a strong young man, in bed, apparently comfortable, and without cough. He seemed to have little if any serious pain, but his countenance exhibited suffering. I ordered cold-water compresses, and left some Dover's powders to be taken at intervals, and I also left some quinine and a couple of bottles of wine for his convalescence. Some months afterwards I met the man in robust health, driving a Rocky Mountain four-horse stage-coach, and with only the external marks of his desperate wound remaining. I understood from him

* Philadelphia Medical and Surgical Reporter, July 28, 1883.

that his recovery had been rapid and without any further hemorrhage or other drawbacks. He seemed to have the free use of his lungs also.

Surgeon Bill, U.S.A., has contributed to Ashhurst's "International Encyclopædia of Surgery" a most interesting article on arrow-wounds.* He says that "arrow-wounds penetrating the chest and wounding the lung, although serious, are by no means mortal. . . . If the patient survives the period of hemorrhage the prognosis is favorable, for the consecutive inflammation is usually trifling, and requires no treatment beyond placing the patient at rest and affording a supply of pure warm air." He also directs that "if the head of the arrow has passed from one side of the chest to the other, it should not be operated upon with a view to removal backward, but should be pushed forward between the ribs until the head can be detached from the shaft, and then the shaft withdrawn." Dr. Bill also states that "if the head of the arrow has been left in the lung-tissue, nothing can probably be done for the patient." In Dr. Bill's table of arrow-wounds of the chest, he shows that in eighteen cases there were thirteen deaths,—about 72 per cent. There were five recoveries.

NEWPORT, RHODE ISLAND, August, 1883.

A CONTRIBUTION TO THE STUDY OF RÖTHELN, OR GERMAN MEASLES.

BY BOARDMAN REED, M.D.

Atlantic City, N. J.

A GOOD many cases of this trifling affection have been observed in Atlantic City during the last six weeks. It is, indeed, so unimportant a disease that it would scarcely deserve to be dignified by scientific study but for the fact that it has been often confounded with a mild form of scarlet fever. True, the differences between them are so well marked that to one thoroughly acquainted with them such a mistake is impossible; but physicians who have not given the subject especial attention and followed carefully the current literature concerning it may well be pardoned for the lack of such a thorough acquaintance with the diagnostic differences, since no one text-book among

the dozen or more which I have consulted contains a complete and wholly accurate account of the minor affection.

One of the best accounts of Rôtheln, or German measles (called also Roseola by some of the older authors), was contained in a paper contributed by Dr. Louis A. Duhring to the *Philadelphia Medical Times* of March 26, 1883. So far as I know, Dr. Duhring was the first to call attention to the fact that in most cases of the affection there is enlargement of the chains of lymphatic glands about the neck, which is sometimes very marked indeed, in other cases very slight. I can fully confirm this observation. The cases I have seen during the recent prevalence of the disease here, as well as those previously observed by me, almost without exception presented this important sign.

Dr. Duhring, in the same paper, gave a clear anatomical description of the eruption in its various phases; and it by no means always presents the same appearance.

Dr. John M. Keating also, a few years ago, gave a full and exhaustive account of Rôtheln in a medical paper which I cannot now lay my hands upon.

Most of the authors who have written in text-books upon this subject (though our own Bartholow, and Dr. Edward Ellis, of England, are notable exceptions) convey the idea that Rôtheln is always a febrile affection, the fever being usually of light grade. Most of the cases seen recently by me were quite apyretic. The children ate as usual, and made no complaints. But for the formidable-looking rash, they would have been allowed to play about without any suspicion of their being otherwise than well. Indeed, I encountered several cases among children seen upon the streets or carried by their nurses into shops, the eruption in these instances being supposed to be "tooth-rash." In some cases, however, there was considerable malaise and an accompanying sore throat. The fever, where any existed, which was very seldom, did not go above one hundred or one hundred and one degrees, and always subsided by the second day.

Another point of importance is that there may be, contrary to the statement of certain authors, some desquamation; but this is never so marked as after scarlatina. Most authors deny that there are ever any

* *Op. cit.*, vol. ii. p. 116.

complications or sequelæ, which is also in accordance with my own experience; but one of my colleagues informs me that he has seen a case which was followed by slight albuminuria and dropsy, and Dr. J. Lewis Smith mentions that these, as well as chronic bronchitis, may sometimes follow German measles.

In two of my recent cases the eruption was very partial, and peculiar in other respects. I was called to see two children, brother and sister, who were supposed to have been poisoned. The boy, aged 5, presented a decided dermatitis involving the whole of both cheeks, with considerable œdema of the lower eyelid on one side, and extending in a less intense form to the sides and front of the neck. The skin was of a fiery-red color and very finely punctated, resembling closely the condition produced by an excessive application of kerosene. The face was also hot to the touch, though the remainder of the body was cool and the temperature and pulse not above the normal. The boy had complained of a slight sore throat, and a mild application of kerosene had been made to the neck for a short time the preceding evening. This would have been deemed sufficient to account for such an evident localized dermatitis, but for the coincident condition of the other child. This one, a girl aged 3, presented a diffuse punctate rose-colored rash over the whole of the thorax, front and back, extending slightly over the abdomen, but not at all to the limbs, and leaving the face entirely free. To complicate the matter further, there were two large, irregular-shaped, fiery-red patches of genuine dermatitis, about three inches in circumference, upon the breast of this child. The chains of lymphatic glands about the neck were slightly enlarged in both cases. These eruptions were somewhat longer in disappearing than usual, persisting for four or five days, but in neither case extending beyond the limits described.

Twelve days later I was called to see a third child in the same family on account of a slight erythema of the fauces, accompanied by a very marked enlargement of the submaxillary gland upon one side, as well as a little swelling of the smaller lymphatics about the neck. There was found a fine punctate rash upon the tonsils and velum palati, but *no rash whatever upon any external part of the body.* Tem-

perature and pulse normal, and appetite good.

The foregoing cases are, of course, open to doubt, but I consider them to have been irregular forms of Rötheln, modified by some peculiarity of constitution common to this family.

Sufficient prominence has not been given to the differences in the pulse in Rötheln and scarlatina. It is seldom or never much accelerated in the former, even when there is fever; it is nearly always greatly accelerated in the latter, and out of proportion to the amount of fever.

In the German measles there is usually no catarrh of the eyes, nose, or bronchial tubes, though slight suffusion of the eyes is not rare.

Coincidentally with the epidemic of Rötheln recently observed here, there were a very few sporadic cases of genuine scarlatina, traceable to convalescents brought from Philadelphia; but the only deaths, two in number, occurred in the family of the proprietor of a boarding-house in the extreme northern part of the town. His children became infected with a severe form of the disease from a little patient who boarded in their house at the latter end of summer.

It is no unusual thing for contagious diseases to be thus introduced here from the cities; but the antiseptic influence of the ocean breezes assists in preventing their spread, while the health authorities, as well as the hotel-proprietors, from the powerful motive of self-interest, enforce such rigid quarantine measures that the contagion, as a rule, is promptly stamped out.

In this connection it is proper to state that the health of Atlantic City is now remarkably good. So far as known, there are no cases of any form of fever existing here.

THE USE OF RESORCIN AND CHINOLINE SALICYLATE IN OTORRHOEA.

BY CHARLES H. BURNETT, M.D.

RESORCIN, $C_6H_4(HO)_2$, is a parabenzene, discovered in 1864 by Hlasiwetz and Barth, and introduced into medical practice in 1877 by Andeer. Dr. E. De Rossi, of Rome, was among the first, if not the first, to use this drug in the local treatment of chronic purulent otitis media. In the *Archives of Otology* (1880,

p. 244) Dr. De Rossi reported that he had then been using resorcin for some months, having in this time employed it in two hundred cases of chronic purulent otitis, and he stated that he felt justified in claiming that no remedy at his disposal had ever given him such substantial results in this obstinate affection as resorcin. Cases which had been unsuccessfully treated with caustics for months, yielded after a few applications of this remedy. Resorcin is soluble in alcohol, glycerin, and water, and it may be used pure or in solution in varying proportions. Its therapeutic value would seem to depend upon its antiseptic properties.

I have used powdered resorcin both pure and mixed with boric acid, one part to seven of the latter, blowing it into the fundus of the canal of a discharging ear after the latter had been cleansed either by syringing or by swabbing with absorbent cotton. After the ear is thus cleansed, a little of the powdered resorcin, or borated resorcin, is taken up by means of a short quill on one end of a piece of black-rubber tubing, the other end of which tubing is held in the operator's mouth. Under good illumination of the canal and its fundus with the forehead-mirror, the powdered resorcin may thus be blown into the drum-cavity, if the perforation in the drum-membrane be large enough. Being disposed to deliquesce, it is not a perfect powder for convenient insufflation when used pure, as it is not easily made into a dust. Hence the borated form is preferable. I have used it also by swabbing the mucous cavity of the discharging drum (by first moistening some cotton twisted on the cotton-holder with water, next mixing some of the pure resorcin into a thin paste until it is absorbed by the cotton, then swabbing the ear with it). It certainly has proved a good remedy in many obstinate cases of otorrhœa.

Chinoline Salicylate.—Chinoline is distinctly related to resorcin. Its properties have been recently investigated by Dr. Julius Donath, of Baja, Hungary. Dr. Sadtler, in the *American Journal of Pharmacy* for February, 1882, p. 81, speaks of chinoline and its salts. Chinoline's formula is C_6H_7N , and it is the first of a homologous series of eight similarly constituted alkaloids, each member of which differs from its predecessor by the addition CH_2 . It is manufactured on a large scale from coal-tar,—chinoline and aniline being

found almost without other admixture in the last portions of the distillate known as "dead oil." It is an energetic bacteria-poison in a one-fifth per cent. solution, and in the same proportion it prevents lactic acid fermentation, although it exerts little or no influence on yeast-cells. It forms several salts, among which the tartrate and the salicylate are best known. The latter being a colorless and amorphous powder, I have chosen it for insufflation in chronic purulent otitis media, or otorrhœa.

In December, 1881, I began to use chinoline salicylate, in an undiluted form, as a powder for insufflation into the ear in chronic purulent otitis media, and also in otitis externa diffusa, caused by the growth of aspergillus in the auditory canal, basing my therapeutic attempts with this drug on its properties as just set forth. It is to be blown into the canal and its fundus by the same simple powder-blower already spoken of when discussing resorcin.

It is a detergent and disinfectant powder, and hence a healing application in the above-named diseases. It is especially potent in the destruction of the parasitic aspergillus, one application having in several cases arrested the growth of the fungus, destroyed it, and thus cured the otitis externa caused by the parasite. I found, however, that when used in the pure, undiluted form the powder caused more or less burning, and if the ulceration lay in the skin, as in the cases affected by the parasitic aspergillus, the use of the undiluted powder in some cases caused pain in the ear.

Therefore, I diluted the chinoline salicylate with eight times as much finely-powdered boric acid, and this has given great satisfaction in my hands, especially as a prompt destroyer of the aspergillus.

The physical properties of chinoline salicylate, it being a very light and amorphous powder, render it most convenient for insufflation, and its known chemical nature would lead us to expect, *a priori*, that it would render good aid in many cases of aural discharge.

Our interest in all forms of powders for insufflation into the ear should be great, as it is now very well established that the "dry treatment" by means of powders is preferable to any other local remedial measure in the great majority of cases of diseases of the ear characterized by dis-

charge of pus, sero-pus, or mucus through the external auditory canal.

Just enough borated chinoline salicylate is to be blown into an ear to dust thoroughly the inflamed surface, but not enough to pack the fundus and the canal. Under the application of both resorcin and chinoline the mucous membrane becomes blanched, the odor of decomposing pus is lessened or entirely removed, and the secretions diminish and then cease. Neither drug is a specific, though chinoline almost approaches it in cases of *aspergillus* in the ear. Both drugs are certainly valuable additions to the surgeon's armamentarium. No one but the writer has recommended or used the chinoline salt in ear-diseases, as far as he knows; but it is hoped that it will receive a trial at the hands of others, and that more facts concerning its action shall be forthcoming.

A NEW FORM OF HEMORRHOIDAL FORCEPS.

BY P. G. SKILLERN, M.D.

SEVERAL instrument-makers of this city have made, at my request, a simple and efficient instrument for extirpating hemorrhoids. It was devised for the purpose for which Smith's clamp has been employed, for which it is a perfect substitute. Perhaps the description of the forceps may be properly introduced by a brief report of a case in which the instrument was used, which will also illustrate the mode of treatment.

Cavalry recruit, aged 22 years, suffering with a large internal pile, the size of a walnut, which disabled him from his duties, applied to me for treatment last spring. I found, upon examining the parts, that the tumor was much inflamed and very painful. It was reduced, and sedative astringent lotions and ointments were applied. In the course of three days it required to be reduced several times. The inflammation having now been relieved, it was decided a proper time to operate. He was etherized, and placed in position on his left side; the hemorrhoid was drawn well down with a tenaculum, the forceps applied grasping the base of the tumor, and it was excised; the stump was cauterized with the actual cautery before the forceps were removed. There was no hemorrhage. He was then given an opium suppository, and four days afterwards was discharged cured, the parts being perfectly clean.

Equally good results have been obtained in other cases. I will now describe the instrument:

The hemorrhoidal forceps is six and three-quarter inches in length, the blade being two and a half inches long and half an inch wide; it is curved on the flat, and has the approximating surfaces slightly serrated, not sufficient to wound the pile,

but just enough to grasp it tightly and prevent any slipping. It is opened by pressure on the handle, which being relieved, the blades close strongly and firmly, and in its grasp will securely hold a thin sheet of writing-paper. In operating, the patient is placed on the left side, with back to the operator, and the instrument applied with handle pointing posteriorly, and between the nates, so as to be entirely out of the surgeon's way; the pile is then cut and cauterized. The blade, being small, can readily be introduced within the rectum through a speculum. The advantages claimed are—first, its simplicity, a very desirable requisite in all surgical instruments; second, its weight and size; third, its facility of application; and last, its moderate cost.

I prefer excision to injection with carbolic acid, because I think it is safer; the patient is relieved sooner and with less suffering. I always cauterize with actual or galvano-cautery. The duration of the treatment is certainly shorter by this method than by any other. I would excise all external piles, also internal piles when the areolar tissue is greatly thickened and the pile made spongy or fleshy by inflammatory deposit and coagulated blood, and think it is safer even to excise the vascular globular variety, if the forceps be well applied and the stump well cauterized.

DEATH OF PROFESSOR DEPAUL.—On the 22d of October, Professor Depaul, the celebrated obstetrician, died at his native place, near Pau (Basses-Pyrénées). He was a commander of the Legion of Honor, member and formerly president of the Academy of Medicine, and one of the committee of publication of *La France Médicale*. He was 72 years of age, and died of pneumonia.

A CASE OF CONCUSSION OF THE BRAIN IN AN INFANT.

BY P. HOOPER, M.D.

E. K., aged 20 months, was struck on the head with a stone while seated in a baby-coach, as I was informed when called to see the case, a few hours after the accident. When I first saw the patient, she was screaming violently at times, as if in intense pain. The pulse was weak and slow, and the temperature below the normal. She had had several convulsions before I saw her,—afterwards none. Hot applications to the feet, spine, and epigastrium were ordered. Later, on the evening of the same day, I saw the patient again. Reaction had now set in. Ice-bags were placed on the head, and one-fifth of a grain of calomel and one-twentieth of a grain of morphia given every four hours. Five grains of bromide of potassium were also given every three hours. After the second day the morphia was discontinued, and two and a half grains of chloral substituted. On the third day the little patient had convulsions on the side of the body opposite the site of injury. The muscles of the face twitched violently, and the toes were in almost incessant motion. The bromide and the chloral hydrate appeared to check the convulsive movements, and it was used during the entire period of the child's unconsciousness. After a few days the calomel was dispensed with, and iodide of potash given to help absorb the clot of blood on the brain. The bowels moved freely during the sickness. The pupils were dilated and the eyelids firmly closed, and unconsciousness was complete.

After reaction set in, the temperature seldom rose above 103° F. The pulse ranged from 160 to 170, and was quite weak and thready. By keeping the ice constantly on the child's head the temperature was kept within 103° F., and whenever it was taken off the temperature rose very rapidly. After the temperature had fallen to 102° F., and even to 101° F., the pulse still kept at 160 and over, still being weak and thread-like, and even after the temperature had reached the normal the pulse still remained high and weak. Milk constituted the diet, with a soft-boiled egg occasionally. Pieces of ice were from time to time placed in the mouth, and were readily cracked and swallowed by the patient. Whiskey was given with the milk,

as the need of it was apparent from the feebleness of the pulse. The ice was kept constantly on the head for two weeks, day and night, and to the touch the head felt almost as cold as the pieces of ice. Two weeks had passed by, and still the child showed no signs of consciousness; the convulsive movements still continued. It now seemed a debatable question whether trephining the skull should be resorted to: if that were done, it did not seem possible that the child could survive: so expectancy and conservatism were deemed proper. Late on the fifteenth day the child said "Yes" to a question asked by the mother, and for the first time showed any signs of consciousness. For several more days she lay at times in a semi-unconscious state, but the improvement in her condition was noticeable from day to day. Later on, tonics (iron and quinine) were given. For several weeks the child was unable to walk, and could not stand on her feet long at a time. She gradually improved; the tonics were not given long after she was taken from her bed. To-day she is perfectly well. No unfavorable symptoms have developed. The stone, which was thrown by a boy into a pear-tree, came from the upper part of the tree,—one of medium height; on being placed on the scales, it weighed a pound.

3509 NORTH SEVENTEENTH STREET.

A CASE OF TYPHOID FEVER, WITH ABORTION IN THE THIRD MONTH—DEATH—ULCERATION OF PEYER'S PATCHES, AND HIGHLY FATTY KIDNEYS.*

BY HENRY F. FISHER, M.D.

L. K., æt. 43, married, German, was admitted to the Episcopal Hospital, September 15, 1883. The following notes were taken by Dr. George M. Boyd, resident physician. She stated, on admission, that she had been sick two weeks, that the trouble began with general lassitude and headache. Her bowels had been loose, and she had passed blood in small quantities. The abdomen was somewhat tympanitic on percussion, and there was pain complained of on pressure over the right iliac fossa, and gurgling on pressure over this region. The patient seemed rather unusually prostrated;

* Reported to the Pathological Society of Philadelphia, September 27, 1883.

tongue coated with brownish fur and very dry.

September 17.—Temperature this evening 103° ; bowels loose; she complains of pain in both lumbar regions, apparently along the course of the colon.

September 19.—Evening temperature 102° ; heart's action weak, but otherwise seems to be doing well.

September 20.—Temperature 103° ; heart very feeble and irregular. Patient presents all the symptoms of profound shock. Menstruation stated to have come on suddenly this morning with much loss of blood. Vaginal examination reveals widely-open os and large uterus. Several large clots were removed, but failed to remove placenta, which was tightly adherent. Hot-water injections and ergot were ordered, with alcoholic stimulants, but no reaction took place, and the patient died at nine o'clock the same evening.

The post-mortem examination revealed numerous enlarged and ulcerated Peyer's patches in the lower portion of the ileum, inflammation also of the solitary glands, and swollen mesenteric glands. The uterus seemed about the size of a uterus at the beginning or middle of the third month of pregnancy. The kidneys were highly fatty.

N.B.—An embryo, it seems, had been passed, but was, unfortunately, thrown away by the nurse with the other discharges.

NOTES OF HOSPITAL PRACTICE.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF WILLIAM PEPPER, M.D., LL.D., PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA, OCTOBER 14, 1882.

Reported by WILLIAM H. MORRISON, M.D.

SUBACUTE INFLAMMATION OF THE CARTILAGES AND PERIOSTEUM OF THE LOWER PORTION OF THE SPINAL COLUMN.

GENTLEMEN,—I bring before you to-day this aged physician because he is an admirable illustration of the beneficial effects of mechanical appliances in certain troubles about the spine.

He is 70 years old, and one of the oldest living graduates of the University, having graduated forty-seven years ago. Until November 1, 1879, he was in good health. He was then taken ill with pain in the

lumbar region of the spine, extending down the legs. The trouble was considered to be lumbago and sciatica, and was treated accordingly, but without benefit.

During the winter he was attacked by violent pain in the lumbar region, followed by jerking, spasmodic movements of the legs. He could not move the limbs without bringing on the pain and spasms from the waist down. Movement of the body brought on spasm of the lumbar muscles. He had no pains in other parts of his body. He says that the explosive pains felt as though caused by an overcharged battery or the discharge of a cartridge in the spinal column. The attacks of pain and spasm continued for three or four days, and recurred every two or three weeks, and seemed to be influenced by changes in the weather.

He was treated by the administration of anodynes, belladonna, atropia, the use of blisters, acupuncture, and the actual cautery, but with little or no benefit.

In May, 1881, he was so prostrated as to be unable to turn in bed without help, and the least disturbance of the spine would induce spasm of the lower extremities. About the middle of June he was admitted to the hospital. An examination at this time showed that there was no trouble about the brain or upper portion of the spinal cord; that the lower extremities were not paralyzed; that there was no paralysis of the bladder or rectum; that the muscles of the legs were soft and perhaps slightly wasted (this was most marked on the right side); and that he had these severe attacks of pain in the region of the lower lumbar vertebræ. These pains were caused by deep pressure along the lateral processes of the lower vertebræ, and also by pressure along the crest of the ilium. No abdominal tumor or aneurism could be found, which, by pressure on the lumbar spine and nerves emerging from it, could cause the fixed local pain and the radiating pains of which he complained. There did not seem to be any reason to diagnose organic disease of the substance of the cord, but rather irritation of its surface and of the nerves emerging from it. There were no evidences of slow progressive degeneration, either sclerosis or softening.

In sclerosis of the posterior columns usually, and sometimes in sclerosis of the anterior columns, there is considerable

twitching of the lower extremities, and a good deal of darting pain. The pain from which this patient suffered differed entirely from that of ataxia. It came on in spells apparently influenced by the weather, and was also provoked by motion, and particularly by anything which caused pressure, or which imparted the least motion to the lower portion of the spinal column. Ataxic pains usually do not have any reference to changes of weather, and no reference to quiet or motion. They are singularly erratic, now in one place, now in another, lasting a short time, coming and going. In this case, however, they were quite protracted and continued. They were also associated with a degree of muscular spasm which was unlike anything met with in the early stage of locomotor ataxia. Lastly, there was intense local soreness, evidently due to pressure. This is not met with in ataxia. The pains were not associated with any paralysis of the bladder, nor was there any disturbance of sensation in the extremities, as is usual in ataxia. Sclerosis, softening of the cord, and chronic myelitis were therefore excluded, and I concluded that his condition was dependent on disease of the bone or of the ligaments and cartilage of a rheumatic or gouty character, and probably affecting the sheath of the lumbar nerves. At this time there was a distinct projection of the eleventh dorsal vertebra. The question therefore came up whether there had been actual disintegration and caries of the bodies of the upper dorsal or lumbar vertebræ, or whether it was simply a subacute inflammation of the cartilage and periosteum. I need not say that it would be very unusual to have a rapid caries develop in a man of seventy, not scrofulous, and who had met with no injury. On the other hand, subacute gouty and rheumatic inflammation is not uncommon under such circumstances.

I ask him to remove his leather jacket, and you see that the spine of the eleventh dorsal vertebra is still prominent. This may have existed before he was taken sick, or it may be due to thickening and infiltration of the periosteum around the spinous process. I did not at any time feel certain of the existence of caries.

The symptoms, evidently, were to be explained by inflammation, thickening, and pressure upon the nerves at this part of the spinal column. The same symptoms mark

the early stage of angular curvature of the spine. There is in this condition pain in the spine, increased by motion, and spasm and radiating pains in the lower extremities, and these increased by motion. This condition may be simulated by an inflammation of a slower character, not going on to disintegration of the bone.

He was kept in bed, on a nutritious diet, and plaster-of-Paris jackets applied at varying intervals. This treatment was followed by relief of the pain. Systematic manipulation of the limbs, passive motion, and massage were employed; passive movements were also made about the lumbar region when the jackets were off. The leather jacket which he now wears was put on last winter. Three months ago he began to walk with canes, and went to the sea-shore; this was followed by improvement in strength and general health. He is at present in very good condition.

During all this time he has taken very little medicine. He had for some time alterative courses of iodide of potassium and minute doses of mercury; during the greater part of last winter that constituted the whole treatment. Under this treatment he has recovered. His recovery, I think, demonstrates that caries did not exist. If there had been caries and disintegration of two vertebræ, I do not think that our patient would be in the condition in which we see him to-day.

Mechanical support is often of great value in medical cases. This is particularly true in painful affections about the spinal column: you will often obtain cures by simple means with the use of such support, where, without them, the most vigorous efforts would fail.

PLEURISY AND EMPYEMA IN CHILDREN.

I shall next show you a little child who has for some time been under the care of Dr. J. H. Musser, and, as it is an interesting case and one worthy of careful study, he has kindly sent it to us for examination.

The child is a boy, twenty months old, who, on the 4th of July last, was taken sick with severe enterocolitis. This was followed by pain in the chest, and the symptoms of pleurisy of the right side. His appetite is good; he does not vomit; he does not sleep well, does not seem to have fever, sweats a great deal, and has lost some flesh.

On examining the chest, we at once ob-

serve an enormous discolored projection, just outside the line of the right nipple, near the lower margin of the ribs, occupying a space two and a half inches in diameter, and projecting an inch and a half from the normal level.

Let us search for other signs. The breathing is labored, and performed entirely by the left side; the right side is motionless. Percussion on the right side reveals under the clavicle a hollow sound quite different from the normal pulmonary resonance; it resembles the sound produced by percussing over a small cavity. The tympanitic resonance which is naturally heard above a large pleural effusion must not be confounded with the tympanitic resonance heard over a cavity. At the second rib, in front, flatness begins, and is continuous to the base of the chest; behind, the whole of the right side is flat on percussion: this, as you know, is one of the most marked physical signs of effusion. On the left side, the pulmonary resonance is perfect, and even a little exaggerated.

Auscultation of the left side reveals exaggerated breathing, and I also hear a few sharp, dry, crackling râles, near the ear, in different parts of the left chest. On the right side there is absence of vesicular breathing, but there is heard a distant bronchial breathing, most marked in expiration. I think that none of you would mistake this for the bronchial breathing of solidification of the lung. You often hear it said that, where there is a large pleural effusion, in addition to flatness on percussion, there is feebleness or absence of the respiratory murmur. This may be taken as a general statement, but that it is not always true this single case would show. This bronchial breathing would not be mistaken for that of solidification of the lung, because, in the first place, you would recognize that it was not formed close to the ear; in solidification it appears to be immediately under the ear; in the second place, the murmur is less marked on inspiration than on expiration, and, if you listen carefully, you will find that it is exactly like the laryngeal sound caused by the difficult breathing. If the person is instructed to breathe with his mouth open, making no noise in the throat, the murmur disappears. Remember, then, that not rarely in cases of large pleural effusion there is heard a distant bronchial breath-

ing, most marked in expiration, which is transmitted from an obstructed bronchial tube, the larynx, or the trachea, through the tense thoracic walls, to the ear.

We recognize that there is a large pleural effusion, and the formation of this tumor does away with the necessity of discussing its character. In children, the effusion rarely remains serous for any length of time, so that the fact that a child has had a pleural effusion for several weeks is almost conclusive evidence that it is purulent.

The treatment of the early stage of pleurisy in children is often unsatisfactory because the disease is frequently not recognized. The symptoms of acute pleurisy in children are often masked by the symptoms of derangement of the stomach and bowels, or by nervous symptoms simulating the onset of some specific fever. In this case, the symptoms first noted were those of violent enterocolitis, and, after these had passed away, examination of the chest revealed pleuritic effusion. In pleurisy, the pain of which the child complains is often not referred to the chest, but to the stomach, or even to the back, or thigh. This difficulty in diagnosis is only to be overcome by the use of the practice of which I so frequently speak: that is, when we are called to see a patient, and particularly if the patient is a child, for it cannot speak and tell us its symptoms, we fail to do our duty unless we examine the patient critically from head to foot, paying particular attention to the condition of the lungs and heart. By doing this, we recognize those symptoms which cannot be masked. In this way we are able to decide that an attack which seems to be one of violent intestinal disorder is, in reality, acute pleurisy, complicated by the intestinal trouble.

Even if we recognize the early stage, we cannot treat acute pleurisy as successfully in the child as in the adult. The treatment should consist of counter-irritation by leeches, and later, when the effusion has occurred, by blisters, or the application of iodine; and of the administration of quinia in large doses to try to prevent the tendency to suppuration. After the fever has subsided, iodide and acetate of potassium, and, if the heart be irritable, digitalis, should be given. The chances are that despite the best treatment it will rapidly run into an empyema; after pus has

formed it must be gotten rid of as soon as possible.

This brings me to speak of the terminations of empyema in the child. The most favorable is that which is going to occur in this child,—*i.e.*, spontaneous perforation through the chest-wall. This takes place much oftener in children than in adults. The point at which the opening forms is usually on the antero-lateral portion of the chest, about the line of the nipple in the fourth interspace; sometimes being as low as the sixth interspace, as in this case.

As soon as the pus is discharged the swelling subsides, and a ragged fistula is left, communicating with the pleural cavity and discharging pus. When the pus escapes, air enters the chest, and pyo-pneumothorax is produced. The lung cannot at once expand and fill the pleural cavity, but, owing to the elasticity of the ribs, they yield to atmospheric pressure, and are compressed. The affected side of the chest becomes contracted, the opposite shoulder elevated, and the spinal column curved; but after a time the lungs begin slowly to expand, the chest assumes its natural appearance, the spine becomes straightened, and the child is as well as ever. This is the ordinary result of this termination in young children.

Unfortunately, the disease does not always terminate in this way. Frequently, hectic fever develops, and the child dies of exhaustion; or, in its weakened condition, some affection of the stomach or bowels occurs, and it dies of intercurrent disease; or a latent tuberculous tendency, which the child has inherited, is developed, and the child dies from an outbreak of tuberculosis; or the pus may concrete into a semi-solid mass, and we have a lingering illness resembling a slow phthisis. The tissues of the child's chest are so soft that they rarely stand the strain long enough to allow the pus to discharge into other parts. In adults, the empyema may open into the stomach, pericardium, or some other cavity; in the child, it occasionally opens into a bronchial tube. This is, next to spontaneous perforation through the chest-wall, the most favorable termination: this usually results in recovery, but not with as much certainty as when the pus is discharged externally.

If the effusion does not quickly disappear under the plan of treatment before

mentioned, you should make an exploratory puncture with a hypodermic needle, or the small needle of the aspirator, in order to determine the character of the fluid. If pus be present, it should be drawn off with the aspirator, and the opening allowed to close. It is always a good plan in children to try the effect of a single puncture; sometimes there is an immediate apposition of the pleural walls, and no further collection of pus occurs. This plan is much less successful in adults; still, it is worth trying. The chances are, however, even in children, that the accumulation will reappear: it then becomes necessary to adopt some more radical plan of treatment. The elasticity of the thoracic walls renders unnecessary such serious operations as making an incision into the chest and removing a portion of a rib. The best methods of treatment are the introduction of a silver tube with a valve, so that it may be opened twice a day to allow the escape of pus, and thorough drainage. The latter is accomplished by arming a strong curved needle with a drainage-tube, passing it in one intercostal space and out of the one above, drawing the tube through and knotting it. The child is able to go about as usual, and the amount of pus gradually diminishes. This plan has succeeded very uniformly in my hands. I have also seen good results from the use of the silver tube. Disinfecting injections are not so necessary in the child as in the adult, for the sinking in of the ribs prevents much pneumothorax.

In this case, expectant treatment is proper, for in a few days the chest will open spontaneously: if it does not, I shall have it lanced. I shall have the patient come back in a month, and we shall see what has been accomplished in that time.

TRANSLATIONS.

THE REMOTE EFFECTS OF ALCOHOL.—At a recent congress, held at Rouen, of the Association Française pour l'Avancement des Sciences, M. Picqué reported a case of fracture of the external malleolus, and abrasions of the face, in a patient presenting the appearance of alcoholism. The following day erysipelas developed in the face, extended to the scalp, and the patient succumbed from hyperpyrexia.

At the autopsy the examination confirmed the diagnosis, and revealed a suppurating synovitis in the articulation corresponding with the fracture; also a cirrhotic liver. The reporter concluded that the erysipelas was aggravated under the influence of the visceral lesions, especially of the cirrhosis of the liver, and that the erysipelas thus aggravated had caused, by auto-inoculation of the individual, the synovitis which nothing else explained. Prof. Verneuil, in discussing this case, pointed out the importance of accumulating a large number of cases in order to determine the influence of diathesis upon the healing of wounds. The fatal result in this case he could only attribute to a modification of the organism from the long-continued use of alcohol, which is also shown by the condition of the liver.—*Revue de Thérapeutique Médico-Chirurgicale*, No. 19.

THE ALKALOIDS OF COTO BARK.—Alber-toni (*Archiv für Exper. Path. und Pharmac.*, September, 1883) discusses the properties of cotoin and paracotoin, derived respectively from the two kinds of bark, coto verum and paracoto. He finds that cotoin does not hinder putrefaction or the development of bacteria. Injected into the jugular vein, it causes dilatation of the vessels of the abdominal cavity; the blood-circulation in the intestines being increased. Therapeutically it is considered of value in diarrhoea accompanying mental disease, in chronic intestinal catarrh, and in looseness of cachectic states, such as phthisis; it is contra-indicated in hyperæmia of the intestines and hemorrhage. Frommüller thought it of service also in restraining the sweating of consumptives. The usual dose is from two to three grains. Paracotoin he regards as a weaker preparation in its physiological action. [Prof. Balz, of Tokio, is said to have treated cholera successfully with three-grain doses of paracotoin given hypodermically. Jobst denies to cotoin any constitutional effects. See U. S. Dispensatory, p. 1624.—ED.]

TREATMENT OF SUPPURATIVE PHLEBITIS.—Dr. Demons recommends active interference in a case of suppurative phlebitis of accessible venous trunks, instead of waiting to determine post mortem the existence of metastatic abscesses in the lungs in order to make out the diagnosis of purulent infection. He treated one case of inflammation of the veins at the

bend of the elbow, following a cut with a razor, by longitudinally cutting down upon the veins, which he found full of pus; this he removed, and cauterized the lining membrane with a solution of chloride of zinc (ten per cent.), covering the part with a Lister dressing. The patient recovered. Since the veterinary surgeons sometimes extirpate the jugular vein under similar circumstances, he asks if this means would not perhaps be preferable.—*Revue de Thérapeutique Médico-Chirurgicale*, No. 19.

ANÆSTHESIA OF THE LARYNX BY TÜRCK—SCHROETTER'S METHOD.—Paulsen, in a communication to the *Monatsschrift für Ohrenheilkunde*, adopted Schroetter's method for producing anæsthesia of the larynx in a case of laryngeal polypus. He applied directly to the larynx pure chloroform, painting the surface twelve times; this provoked a hyperæmia of the mucous membrane, which favored the absorption of morphia, which was applied in the same way (a ten per cent. watery solution of the muriate of morphia). He advised the patient not to swallow during the application, and after each painting to gargle with a solution of tannin. Twelve hours after this preparatory treatment the larynx in all parts was insensible to the contact of the sound. The extirpation of the tumor was then readily accomplished. The proceeding is troublesome and disagreeable, and is to be resorted to only in cases of necessity.

INOCULATION OF ERYSIPELAS.—Dr. Fehleisen, in a paper read before the recent Congress of the German Surgical Association at Berlin, reported the results of numerous culture-experiments made with the micrococcus of erysipelas, and also some clinical cases in which the cocci were introduced into tumors. He also presented a patient who had the usual appearances of genuine facial erysipelas, who also had lymphoma of the neck, for which the inoculation had been made. The preparation used was the thirty-fourth generation of gelatin culture of the erysipelas germs; one inoculation was made, and on the following morning the patient had a chill, and at the same time the points of inoculation exhibited erysipelatous redness, which subsequently spread to the face.—*Berliner Klinische Wochenschrift*, No. 20.

EDITORIAL.

THE CRUISE OF THE "CORWIN."

THE United States revenue-cutter "Corwin" was sent in the spring of 1881 to the Arctic Ocean in search of the unfortunate "Jeannette" and the crews of two missing whaling-vessels. She sailed from San Francisco on May 2, and returned in October, having visited Alaska at intervals along its entire coast-line from Behring's Straits to Point Barrow, including Kotzebue Sound, also the Siberian shore from the Straits to the North Cape, landing on Herald and Wrangel Islands, and on returning spending some time at Ounalaska, one of the Aleutian Islands. Science having put the expedition under contribution, a valuable report* has recently been issued by the government, containing some very interesting information, consisting of medical and anthropological as well as botanical and ornithological notes and memoranda.

The birds of the Behring Sea and the Arctic Ocean were made a subject of systematic study by E. W. Nelson: this paper is illustrated by a number of chromo-lithographs, and contains the results of five years' previous study at Saint Michael's, Alaska, as well as the observations taken upon this expedition. Some botanical notes are contributed to the work by John Muir; but the most interesting portion to us is the first section, by Dr. Irving C. Rosse, who makes a very interesting report of his medical and anthropological observations. He notices the practical demonstration of the well-

known fact that our sensations of cold and heat are not regulated directly by the rise or fall of the thermometer, but are largely relative, as a temperature steadily below zero was not only well borne but did not cause discomfort to the party; he also remarked the curious circumstance that cold weather and exposure were better sustained by the ship's crew than by the natives. On the other hand, when the temperature indicated by the thermometer was 60° (F.) the heat of the sun was almost overpowering to the sailors. This leads to a practical distinction by Dr. Rosse between "physical" and "physiological" heat or cold.

He found that while the ethnical points that distinguish the Eskimo from the North American Indian are distinctly marked, this cannot be said to be the case between the Eskimo and the so-called Tschutshi of the Asiatic coast. Reasoning from this and other facts, Dr. Rosse considers them of Asiatic origin, a view which receives further confirmation from their ability to cross Behring's Straits in boats, and from their practice of tattooing themselves, a custom which was evidently brought from Japan. He says, "Natives cross and re-cross Behring's Straits to-day on the ice, and in primitive skin canoes not unlike Cape Cod dories, which have not been improved in construction since the days of prehistoric man." Indeed, for some unknown reasons, their development ceased at the hunting and fishing stage: they are therefore the living representatives of the race that was contemporaneous with the cave-bear and mammoth in Europe. In some particulars Dr. Rosse differs from other Asiatic voyagers in some of his impressions of the Eskimo, or Innuits as they call themselves. According to his experience, they do not have the enormous appetites with which they have been credited; indeed, several of them, who accompanied the party, invariably ate less than the sailors did. It is true that when half famished they will eat

* Cruise of the Revenue-Steamer "Corwin" in Alaska and the North-West Arctic Ocean in 1881. Notes and Memoranda, Medical and Anthropological; Botanical; Ornithological. Washington, Government Printing-Office, 1883. 4to, cloth, pp. 120.

to repletion; but so will Europeans. He observed that a day's tramp in the sharp crisp air of the Arctic regions will develop such latent gastronomic capabilities in any vigorous man as will surprise him, and the Eskimo are not exceptions to this; but the popular notion of their enormous appetites is set down as a current fallacy, partly due to some of the repulsive articles of their dietary.

Contrary to general opinion, also, it is stated that their intellectual capacity is by no means feeble; they learn quickly, show great aptitude for trade, and acquire languages easily. Examination of their skulls does not indicate the low grade of intellectuality which they are commonly credited with, but they are well formed, and possess large brain-capacity, averaging as high as the French or Germans. They are honest, truthful, and good-natured, except when they have been corrupted by the bad examples of white men. Their ideas of family and sexual morality are low, their religion simply Shamanism. He saw nothing that would give foundation for the current belief that the dwellers under the Arctic Circle have less active sexual passions than those of warmer climes. The "heyday in their blood" is not cooled to any appreciable extent by their icy environment. With their intelligence and capacity for improvement, this would seem a most promising field for missionary labor. In the terms of Dr. Rosse, it affords "a brilliant opportunity for some one full of propagandism and charity to imitate the acts of the modern apostles, and extend the influence of civilization to the gay, lively, curious, and talkative hyperboreans whose home is under the midnight sun and on the borders of the Icy Sea." Attention is directed to their mal-hygienic mode of life, and, in consequence, to the terrible ravages made by epidemic diseases among them. They also suffer greatly from the deleterious effects of alcoholic liquors of very inferior

character, which are surreptitiously sold by traders under the names of "Pain-Killer," "Bay Rum," "Jamaica Ginger," "Florida Water," etc., which he found to be only cheap alcohol with a little coloring-matter added. Although the taste is an acquired one, they seem to have an uncontrollable craving for alcoholic drinks, frequent indulgence in which favors their extermination by famine. With regard to the use of alcoholic drinks by Arctic voyagers, Dr. Rosse considers them almost a physiological necessity, if employed in moderation. He believes beer and claret to have especial value as anti-scorbutics, when taken with food, during an Arctic voyage; and he considers that it would be better for the natives from a moral point of view if these could be substituted for the adulterated drinks referred to, or used in place of "kvass," a vile native decoction made from sugar and flour, which are obtained in unlimited quantities from the traders who are forbidden to deal openly in alcoholic liquors. As Alaska and the Aleutian Islands are now a part of the United States, these reports, records of personal observations of the inhabitants of these places, are of especial interest and value.

RESULTS OF THE LABORS OF THE CHOLERA COMMISSIONS IN EGYPT.

THE official report of Dr. Koch's commission on the cholera in Egypt, with the results of his investigations, has just been published in the *Imperial German Gazette*.* Although the epidemic was on the decline when the Commission arrived in Alexandria, the objects sought to be attained by its appointment were kept prominently in view, and quarters were obtained in the Greek Hospital, where the necessary examinations and experiments were made. The autopsies were conducted

* Medical Press, October 24, 1883.

with great care, directly after death, in order to avoid changes incident upon putrefaction. Specimens of blood of typical cases of the disease and of their ejecta and excreta were also carefully examined. While the dissection of the corpses proved beyond doubt that the patients had really died from cholera, and not from diarrhœa or so-called cholérine, it was further demonstrated that in the intestinal tract there existed a peculiar form of bacteria in the utricular glands of the mucous membrane, and proliferating between the epithelium of the gland and the basement membrane, which was also found on the villi and even penetrating into their substance. In grave cases, with bloody infiltrations into the mucous membrane, these microbes were very numerous, and extended as deep as the muscular layer. Their favorite site appeared to be in the lower part of the small intestine.

These bacteria are rod-like, and therefore belong to the bacilli; they come nearest in size and form to the bacilli found associated with glanders. Dr. Koch, however, makes the significant statement that "if this discovery had not been made in perfectly fresh corpses, one could have made but little use, or no use at all, of it, for the influence of putrefaction is able to bring about similar bacterial vegetations in the intestines."* To determine the question whether these bacteria are the primary manifestation of the disease in the intestine, or are preceded by general infection, will require further study, and the Commission will proceed to India to continue its scientific investigations, the epidemic in Egypt having subsided. Thus far only a few culture-experiments have been made, but all attempts to communicate the disease to the lower animals, including monkeys, have failed. In the hos-

pital, however, a laundress exclusively engaged in washing the linen of cholera patients was seized by the disease, which would lend some weight to the opinion of its possessing a truly contagious character, a view which seems to be gaining ground among medical men in India.†

Altogether, the results obtained have answered the original purpose of the preliminary investigation; but additional work is needed to solve finally the problem of the cause of cholera and to formulate the laws of its development. The fact that the disease has declined to such a marked extent in Egypt suggests the thought that peculiar conditions are required, or a special pabulum provided, in order that the disease may prevail epidemically, and that where these no longer exist the disease disappears.

In the *Egyptian Gazette* of September 27 there is contained a preliminary report of Surgeon-General Hunter, of the English Commission. From this‡ we learn that he obtained evidence, conclusive in his opinion, that cholera is endemic in Egypt, and that it had existed for some time before its appearance at Damietta, the cases being reported as diarrhœa or cholérine. He stated that the disorder giving rise to many of the cases of diarrhœa, which is so common and so fatal in Egypt, is in reality only a form of cholera. These views are opposed by Drs. Sierra and Vassalopoulos, of Alexandria, who maintain, in communications published in the *Progrès Médical*, the essential distinction between sporadic and Asiatic cholera, and insist that the latter was imported into Egypt from its habitat in India. The Board of Health of Alexandria has since issued a manifesto protesting against the views of Dr. Hunter "as tending to mislead public opinion and to encourage the belief that the cholera has been endemic

* "Wenn dieser Befund nicht an ganz frischen Leichen gewonnen wäre, dann hatte man ihn wenig oder gar nicht verwerthen können, weil der Einfluss der Fäulnis an Stande ist, ähnliche Bacterienvegetationen in Darm zu veranlassen."
—*Berlin. Klin. Wochenschrift*.

† Paper. by Brigade-Surgeon Scriven, *British Medical Journal*, October 27, 1883.

‡ *Medical Times and Gazette*, September 29, 1883, p. 377.

in Egypt since 1865."* It will, however, require more than a protest to remove the filth, overcrowding, and entire neglect of sanitation discovered by Dr. Hunter in Egypt, which afford a suitable soil for the propagation and extension of cholera so graphically described in his further Report,† and which make his conclusions worthy of serious consideration.

PROPAGATION OF DISEASE BY BOOKS.

THE *British Medical Journal* having recently editorially directed attention to the danger of the spread of contagious diseases by borrowed or second-hand books, the article has been extensively copied into other medical journals, and, as a rule, without comment. The danger seems to be practically quite a remote one, since the loaning of books, which is carried on by the great circulating libraries in England to a much wider extent than anywhere in this country, has not given rise to the serious consequences which have been feared. In this age of preventive medicine and investigation into the causes of disease, no such active source of contagion could have escaped notice in case it really existed. There are several reasons why we may dismiss apprehension of this from our minds as a prominent or even as a subordinate source of disease under ordinary circumstances. In the first place, cases of variola, scarlatina, and measles—for these are probably the only diseases that might be at all supposed to be communicated by such means—are usually isolated by those in charge, and would not be allowed to read books, even if they should wish to, during the period when the disease is most communicable. We do not regard it as supposable that typhoid fever could be communicated in this way, although mentioned by the writer of the article referred to. Secondly, reading-people are sufficiently

intelligent and careful not to give borrowed books from a circulating library to a case of zymotic disease, even though the danger be a remote one. Thirdly, the manner in which a book is used is not favorable to acquiring or conveying the contagium, if there is such an entity. There are many sources of contagion that are much more important: paper money, for instance, which passes from hand to hand and is generally carried about the person; the furniture in the waiting-rooms at railroad-depots; the street-cars, with their cushions and dirty straw; the city hacks; the pawnbrokers' shops; even the air we breathe often contains epithelial cells and bacilli and spores innumerable, and in that of hospital wards peculiar bacteria have been detected. The recommendation to keep the books used by patients suffering with contagious diseases from being carried into other wards is certainly judicious, and is already adopted in our general hospitals, to which, however, such cases, as a rule, are not admitted: should they get in by accident, they are kept rigidly secluded and quarantined. The application of these rules to books, therefore, can scarcely be said to extend outside the walls of hospitals.

LEADING ARTICLES.

OPIUM-SMOKING.

THE Chinese practice of smoking opium has been the theme of a great deal of discussion, rather of a political and ethical character, however, than medical. Within a short time articles have appeared in several medical journals, which indicate that the subject is now beginning to attract the attention which it deserves, and it is possible that we may soon arrive at a clearer knowledge of the real cause of the peculiar effects which are known to follow this method of using the drug.

Dr. J. G. Kerr,‡ in a short communication, describes the modes of preparation of the watery extract, which is made under

* *British Medical Journal*, October 27, p. 841.

† *Medical Times and Gazette*, *loc. cit.*

‡ *Medical News*, October 13, 1883.

the supervision of the British government, and explains the method pursued by the natives, as follows:

"The smoker, lying on his couch or divan, with the pipe, lamp, and other implements on a tray, takes a portion of the opium-extract on the point of a wire and warms it carefully over the flame of the lamp. He dips it again in the little jar of opium until the requisite quantity adheres, alternately warming it over the flame of the lamp and pressing it on the flat bowl of the pipe, turning it over and over, and working it carefully on the end of the wire until it is reduced to the state of a soft solid by the evaporation of a portion of the water contained in the semi-fluid extract. During this process it swells up into a light porous mass from the formation of steam, and it must, therefore, be heated up to the boiling-point of water, and the presence of water prevents combustion.

"When the little bolus is brought to the exact state fitted for smoking, being still a soft solid, it is worked into a ring around the wire, the point of the wire inserted into the round hole of the pipe, and by twirling the wire around while withdrawing it the opium is deposited on the pipe and adheres to it, the hole in the ring of opium corresponding to the hole in the bowl of the pipe.* The stem being now applied to the lips and the bowl held over the lamp, the flame is drawn in over the opium, converting into vapor all the volatilizable material it contains. To understand what takes place it is important to note that preparatory to smoking the opium has been slowly and carefully heated until steam has been formed in its substance. While in this heated state and with water enough to prevent charring and to form more steam, the flame of the lamp is drawn over it by successive inhalations, producing the so-called smoke and leaving a solid residue, the 'in-she' or 'secoñds.' The smoke is inhaled into the lungs and comes in contact with the immense surface of the respiratory mucous membrane, and through it acts upon the system."

The physiological effects of the inhalation of the smoke (or more properly, as pointed out by Dr. Kerr, of the vapor mingled with the products of combustion

from the lamp) are not described in this article, as they are supposed to be generally known. Stupefying and narcotic in its immediate effects, when indulged in as a practice and to excess it produces emaciation, anæmia, and sluggishness, destroying healthy activity of mind and body, and rendering the victim unfit for performing life's duties, favoring early death, and possibly suicide. It is true, however, that many indulge occasionally in the pipe without any very evident ill effects, and a fatal narcosis from the immediate action of the opium when used in this way is unknown, thus differing materially from the other forms of opium-addiction.

Mr. Hugh McCallum has recently written in the *China Review* an interesting article on opium-smoking,† in which he claims that the effects of opium-eating and opium-smoking are not analogous, and, in fact, are altogether different. Knowing that the principal narcotic agent contained in opium is largely destroyed by the prolonged boiling and baking over a naked fire in an open vessel, according to the process generally followed in preparing the drug for smoking, and that only an infinitesimal quantity of morphia could be inhaled in the act of smoking, if any, he proceeded to test practically the question whether the effect of the pipe is in proportion to the amount of morphia contained in the drug. Making a number of preparations of different morphia strength and giving them to experienced smokers to use and report, he found not only that they were unable to appreciate the difference, but that the preparation of the highest morphia strength was considered as not being as good as another alike in every other respect, but containing only one-half as much morphia. Opium *minus morphia* was pronounced very good by an old opium-smoker, who on another trial smoked an equivalent of twenty grains of morphia in about twelve hours without unusual effects. The Chinese expert bases his opinion of the drug upon the physical appearance of the extract, its behavior in the flame of the lamp, and its smell, not on its effect when smoked: his judgment, therefore, is not governed by the alkaloid richness, but by other qualities. Some specimens were likewise submitted to these experts with a similar result: they were

* This is not properly a bowl, but a flat surface with a hole in it.

† See also *Druggists Circular and Chemical Gazette*, October, 1883.

unable to sort them according to their true value. Dr. McCallum says in conclusion, as the result of his investigations,—

“We have an opium expert, a man whose occupation is to judge of the quality of opium for smoking-purposes, gravely asserting that the Hong-Kong farmer’s best quality of ‘prepared opium,’ containing seven per cent. of morphine, is not good. Not only that, but he condemns the same opium altogether when it contains fifteen and twenty-five per cent. of *added* morphine, and states it is not opium at all. At the same time, opium practically containing no morphine receives only qualified condemnation. The old opium-smoker does not recognize the same differences as the expert. He classes prepared opium containing seven per cent. of morphine, the same opium with fifteen per cent. of morphine added to it, and an opium practically free from morphine, together, all as being equally good. An opium containing twenty-five per cent. of added morphine is stated not to be good. Such statements could never have been made had these men based their judgment on the well-known effects produced by opium and morphine when eaten. Had any one dared to make a similar series of experiments on opium-eaters, there cannot be the shadow of a doubt but the experimenter would have made the acquaintance of the coroner’s court and been indicted for manslaughter. Although these facts show that morphine has little if anything to do with the pleasure of opium-smokers, it cannot be denied that they appear to derive much pleasure and consolation from their pipe. Whence the pleasure? What gives rise to it? What are the temporary and permanent effects caused by smoking opium? These are questions that have not yet been satisfactorily answered; yet they ought to be, and in a scientific manner. Until this is done, the Anti-Opium Society and its supporters are not justified in branding the opium-trade with infamy, or the lovers of a pipe of opium as degraded beings.”

Similar views to the above are expressed in a little work published last year in England, entitled “The Other Side of the Opium Question,” written by Mr. W. J. Moore, who declares that the drug is “a comfort, a solace, a necessity, and often a blessing” to the Chinese. Certainly we would not wish to substitute for it any

other form of opium-indulgence with which we are acquainted, and cannot believe that the evil effects of opium-smoking are at all comparable to those of the abuse of alcohol, which is the bane of “Western” civilized life.

NOTES FROM SPECIAL CORRESPONDENTS.

TOKIO.

RUMORS of the prevalence of Asiatic cholera in the China ports and beyond are continually reaching us. Thus far, however, but few cases have occurred in Tokio or any of the open ports of Japan, and the near approach of cold weather will, it is hoped, prevent any further spread in this direction. Swatow, in China, was recently declared by the Central Board of Health to be infected with Asiatic cholera, and accordingly a medical inspection at the open ports, and detention if necessary, of vessels coming from Swatow, were ordered by the authorities.

The experience of the past few years seems to point to a periodicity in the visits of cholera to these islands,—slight epidemics occurring in localities every other year, and more severe epidemics every fourth year. The type of cholera sometimes epidemic in Japan, although true Asiatic, does not seem to be of so virulent a character as that met with in China and India, a fact in all probability due to a better system of public sanitation existing here than in either India or China.

Kakke, or *beri beri*, a disease characterized by general muscular degeneration and nerve-atrophy, and in some forms accompanied by extensive anasarca, is just now claiming many victims in Yokohama and at the capital. As kakke patients, if not too far gone, rapidly recover by sojourning a few weeks in the mountains, the number of deaths seems low compared with the severity of the disease. In an article upon the diagnosis and treatment of kakke in the *Philadelphia Medical Times*, the acquirement of a better acquaintance with this disease on the part of physicians at home, and especially in large cities, was urged, as it was therein stated that foreigners frequently come to our shores suffering from this disease or bearing its seeds in their systems. In this connection, the following, taken from one of the Yokohama papers, is not without interest:

“The arrival of the *Riujo-Kwan* at Honolulu, with a number of cases of *Kakke* on board, would seem to have created some alarm in that port. We judge so, at least, from its having been found necessary to publish the following certificate:

"H. I. J. M. S. "RIUJIO KWAN."

"Medical Report on the Sickness.

"We the undersigned, G. Trousseau, M.D., and Arthur Mouritz, M.D., have, this third day of July, 1883, visited the Japanese war-ship "Riujio Kwan," by order of the President of the Board of Health.

"After a short interview with the captain, we visited the quarters of the seamen, and were shown by the doctor twenty-six men laid up in their hammocks. These men are all suffering from a disease peculiar to Asiatic races, principally the Japanese and Chinese, and known in Japan as kaki or kakke, and in the medical world as Beriberi (French name). We are thoroughly familiar with the disease, rather prevalent in the Hawaiian Islands amongst the Chinese laborers. Our opinion is that the disease is non-contagious, mostly induced by food-poisoning, although the cause of the disease is, we confess, rather obscure. The captain wishes to land the twenty-six sick men in Honolulu, hire a suitable house, beds, etc., to accommodate thirty people, and have the ship's doctor to attend upon them during the stay of the vessel in port, probably three or four weeks.

"We see no objection to the President of the Board of Health allowing such a course, without any restriction whatsoever, although under all probabilities some of the patients will die during their stay in port. We only mention this fact so that no foolish scare should take place; and it might be advisable, in case the men were allowed to land, to publish a statement of the above-mentioned facts.

"G. TROUSSEAU,

Port Physician.

"ARTHUR MOURITZ."

The patent-medicine men of the land, both of old and new schools, seem to be thriving, as numerous sign-boards at shop-doors and an increased number of advertising agents in the streets do testify. The idea of the "sandwich man" method of advertising, so popular in America and England, has not yet been thoroughly grasped by the patent-medicine proprietors of this land, as no near approach to it has yet been made. The ingenuity, however, displayed in this direction shows that they are very apt scholars, while the implicit faith placed in all kinds of medicine by the common people makes this method of obtaining a living, one would say, very remunerative.

The proprietor of one of the largest daily newspapers is said to have made a fortune by the sale of an eye-wash labelled "collyria" in English, with directions, etc., in Japanese, which wash consisted of a solution of zinc sulphate in water, a solution of course of value in some cases.

Foreign patent medicines are also popular, but their use is, of course, more limited, on account of their comparatively high cost.

Foreign pain-killers, various compound syrups of hypophosphites, anti-sea-sick remedies, and the like, are much used, while native imitations are not wanting. A wise government has, as in the case of native proprietary medicines, required a chemical analysis to be made of all foreign medicines of this character imported and offered for sale, a step which has resulted in the refusal to admit for sale one at least of our most popular nostrums.

Drugs, medicines, and chemicals are still imported into the country in large quantities, the total amount of which would seem, however, a falling off as compared with previous years, to be accounted for in a great measure by the fact that although larger quantities of remedies found in our Pharmacopœias are annually prescribed, yet the botanical resources of the country and the increased facilities for the manufacture of medical preparations are such as to permit of their being prepared at home.

The British consul at Yokohama, in his summary of trade for last year, just published, gives as the total import value of drugs, medicines, and chemicals, the sum of (Mexican) \$394,624, to which amount quinine contributed \$40,301, and santaline nearly \$25,000, equal to 90,000 ounces. It is further stated that 34,000 pounds of bromide of potassium were imported. The importation of morphia amounted to about 6000 ounces.

The rapidly-increasing employment of Western remedies, together with the increased popularity of our methods of treatment based upon really scientific investigation into the causes of disease, contrasts very favorably with the slow and painfully conservative action of the native physicians of China.

CHICAGO.

THE fifth annual report of the Illinois State Board of Health, which is to appear shortly, will contain the following interesting matter relating to medical education and the practice of medicine. In June, 1880, the Board appointed a committee to formulate a schedule of educational requirements and characteristics by which the good standing of medical schools might be determined. This step was found necessary in order to enable the Board to better discharge the duty required of it by the Act to Regulate the Practice of Medicine in the State of Illinois, by which act the Board is directed to issue certificates to all who furnish satisfactory proof of having received diplomas or licenses from legally-chartered medical colleges in good standing. A schedule was prepared by the committee, and subsequently adopted by the Board as the standard entitling to recognition as the basis for legal qualification for practice in Illinois. Previous to that time a very small minority of the medical colleges of the country demanded

evidence of a good English education as a preliminary to the commencement of medical studies. The Illinois Board exacted these conditions: the several minor branches of mathematics, English composition, elementary physics, and natural philosophy, to be followed by actual attendance upon lectures. It further announced that, after this declaration, diplomas of colleges whose educational requirements and methods fell below the schedule would not be recognized as entitling their possessors to certificates from the Illinois State Board of Health. The conditions presented are especially important to students intending to practise in Illinois, as, unless their diplomas are from colleges in good standing, as thus defined, the only other method of entering practice in this State under the law would be by passing a satisfactory examination before the Board. The schedule of the Illinois Board has been adopted by the Missouri State Board of Health and the Minnesota State Board of Medical Examiners.

The report gives a full compilation of the medical laws of the various States and of Canada, together with a summary and analysis of colleges and students. The total number of colleges given is two hundred and eighteen, of which two hundred and four are in the United States. Diplomas have been presented to the Illinois State Board from one hundred and nine colleges, all but six of them being in the United States. Heretofore eighty-five of these have been recognized, sixteen rejected, and nine have been recognized conditionally. There were previously only forty-five which exacted a preliminary examination as a condition for matriculation, while at the present time there are eighty-two; and of those requiring an attendance on three or more courses of lectures before graduation, the number has been increased from twenty-two to twenty-seven. A total of fifty-three require a thesis as a condition of graduation, sixty-four have chairs of hygiene, and seventy-two have chairs of forensic medicine. There are seven colleges exclusively for women, the United States having five and Canada two. There were 12,502 matriculants for the session of 1882-83, classified as follows: regular, 10,402; homœopathic, 1204; eclectic, 824; and physio-medical, 62. The graduates numbered 4143. There are twenty-eight different institutions not recognized by the Illinois Board.

CHICAGO, November 5, 1883.

NOVEL CAUSE OF TINNITUS AURIUM.—An exchange mentions an instance of a gentleman who was much annoyed by crackling noises in his ears at night, which kept him from sleeping. An old lady suggested that there might be maggots in the feather pillow, which was found to be a correct diagnosis. Better in the pillow than in the head!

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

At a meeting of the Society held October 17, 1883, the President, Dr. W. M. Welch, in the chair, Dr. Arthur Van Harlingen read a paper on

THE TREATMENT OF PSORIASIS.

Psoriasis is one of the commoner skin diseases met with in this country. The statistics of the American Dermatological Association show that it occurs in the proportion of about six per cent. in all diseases of the skin encountered. Daily experience would seem to indicate a still more frequent occurrence, because the affection is a disfiguring and annoying one, and therefore patients are more inclined to seek relief, and also because it is a stubborn disease and greatly prone to relapse. The history of a single case will often extend over many years and bring it under the observation of a number of different physicians.

It is because of the comparative frequency with which psoriasis is met and its stubbornness to treatment, that I have selected it as the subject of my remarks this evening. Having had a good deal of experience in the treatment of the commoner forms of the disease, it is my intention to confine myself chiefly to the consideration of such remedies as have come under my own observation and use, only touching incidentally on others.

The object of treatment in psoriasis is the removal of the eruption as it exists upon the skin. We cannot hope with any degree of certainty in any given case to prevent a recurrence of the disease, or, if you please, a relapse. For the drug has not yet been discovered which will surely take away all tendency to the recurrence of psoriasis, and whoever promises a cure, in the wider sense of the word, to his patient, will, in a very great number of cases, find that he has been too sanguine. Fortunately, however, a certain number of patients do seem to recover. I do not know what has been the experience of others in this respect, but I have patients who have been under observation three, five, even eight and ten years without relapse. Such cases are, unfortunately, few.

Pre-eminent among the internal remedies which are useful in the treatment of psoriasis is arsenic, which may be justly called a specific in this disease. I think I am not asserting too much when I say that eight out of ten cases of psoriasis of average character and severity shall do better under the use of arsenic than with any other remedy. I prefer Fowler's solution given in the average dose of four minims thrice daily. I think this solution is often prescribed in too large doses, and I am sure the dose of five to ten minims, as given in the books, is too large for ordinary

use. Most patients bear a four-minim dose very well, but there are idiosyncrasies. I have sometimes been obliged to limit the dose at the beginning to one minim in cases where subsequently such toleration has been established that twelve minims have been taken with impunity. However, four minims is a good dose to begin with, and if the effect does not begin to show itself within ten days or two weeks, the amount may be gradually increased. Fowler's solution should never be given to the patient in a vial with directions to drop out the requisite number of drops. The patient is apt to make a mistake, vials of different sizes may pour out more or less in each drop, and there is always danger in leaving a half-empty vial of poison about the house. The solution is better given mixed with water, or with wine of iron or other convenient vehicle.

The effect produced by arsenic upon the eruption of psoriasis is, first, in diminishing the quantity of epidermic scales thrown off, and then in preventing the appearance of new lesions. The patches gradually lose their scalliness, begin to heal in the middle, and disappear little by little. It must be remembered, however, that arsenic is a slowly-acting remedy, and its use should be continued through many months to get the best security against relapse.

The other liquid preparations of arsenic used in psoriasis are Pearson's solution of the arseniate of sodium, and Donovan's solution of the iodide of mercury and arsenic. I have used the former in a few cases without noticing any perceptible difference as regards efficiency between it and Fowler's solution. The solution of mercury and arsenic (Donovan's) I have employed in certain stubborn cases with good effect where Fowler's solution has seemed to fail. The existence of syphilis as the cause of the eruption in these cases having been excluded, I am at a loss to account for the apparently greater efficacy of the mixed treatment. The dose given was as much as ten drops, and although this solution is weaker in arsenic than Fowler's, yet I am inclined to the opinion that the conjoint administration of the two drugs, mercury and arsenic, was the cause of the good result, rather than the increased dose. I should be inclined to use Donovan's solution in cases where Fowler's solution shall have failed.

The mixture of arsenious acid, black pepper, and sugar of milk, known as Asiatic powder, and recently placed in the Pharmacopœia, with the pepper left out, among the triturations, is of no particular value above the other preparations, and is not so convenient of administration.

Hypodermic injections of solutions of arsenic have been employed, but I have had no experience in their use.

Next in value to arsenic in the treatment of psoriasis is iron. I commonly employ the

tincture of iron in cases where arsenic does not seem indicated. There is one type of psoriasis which includes robust, rosy, well-nourished individuals, "the very picture of health." Such people have never been sick a day in their lives, or perhaps may have had slight attacks of articular rheumatism. Such patients do well under arsenic.

But there is another type in which the individual is thin, poorly nourished, and perhaps somewhat anæmic. These are the cases which do well under iron, which is best administered in the form of the tincture of the chloride. With these two remedies, arsenic and iron, I usually succeed in curing ordinary cases of psoriasis, adding in rare cases cod-liver oil to the use of the tincture of iron when debility is present. Of course local applications are employed at the same time. Of these I shall speak presently.

In addition to the internal remedies mentioned, quite a host of others have been employed from time to time. Such are tar, carbolic acid, copaiba, phosphorus, tincture of cantharides, tincture of maize, carbonate of ammonia, acetate of potassium, and other diuretics; the alkalies, as liquor potassa and the alkaline mineral waters. Of these I have found alkalies and diuretics useful in cases where a markedly inflammatory condition of the skin has existed. The other remedies I have not employed, nor do I think the reports of their usefulness based on a sufficient number of facts, except in the case of tar possibly, to make it worth while to try them.

Equally important with the internal treatment of psoriasis is the external management of the disease. It is, of course, desirable to remove the eruption as soon as possible wherever it may be situated; but when it is found upon the face there is every reason to attempt its cure by all means and in the shortest time. External and internal treatment should therefore be combined when practicable. The first thing to do is to remove the scales. This may be done by means of local or general baths, wet dressings, etc., or by inunctions with fats and oils, by the use of soap, or by the action of impermeable dressings of india-rubber or oil silk. When only a few lesions are to be acted upon, a solution of salicylic acid in alcohol, 1 part to 16, well rubbed in with a sponge, will remove the scales very nicely.

The scales having been removed, the next thing is to apply such substances to the diseased patches as may most quickly modify the abnormal condition of the skin and bring it back again to a healthy condition.

An innumerable number of applications have been recommended for this purpose, the most of which I shall pass over with only a mention. Such have been soaps and alkalies, citric and hydrochloric acids, sulphur, iodine, and mercury, alone and in combination, together with the various forms and preparations of tar, creasote, and carbolic acid.

All of these remedies have their uses, and most of them, especially the tarry preparations, I have employed time and again in years gone by, and with moderate satisfaction. The introduction, however, of chrysarobin or chrysophanic acid, some six or seven years ago, put quite a new face on the local treatment of psoriasis; and since then, with the aid of this and other later discoveries, we are able to work a much more rapid change in the appearance and condition of the skin in this disease.

As chrysarobin is perfectly well known to all here present, both as to its advantages and as to its defects, I shall say but little about it in the ordinary form of its application, namely, as an ointment. When it first came out I tried it quite extensively, but its disadvantages seemed so great that I had already begun to restrict its use greatly in my practice, when a new agent appeared, which for every-day use has in my hands, until very recently, almost entirely superseded all other local applications. I refer to pyrogallallic acid.

I do not think pyrogallallic acid is by any means so well known as an application for the relief of psoriasis as is chrysarobin. If I may judge by the infrequency with which its virtues are mentioned in the journals (although I believe all recent text-books speak of it), it is not in general use. But it is, in my opinion, one of the very best remedies we have for the cure of cases of psoriasis of average severity. Employed in the form of ointment, of the strength of one-half to one drachm of the pyrogallallic acid to one ounce of simple ointment, the effect produced by it is almost as rapid and decided as that brought about by chrysarobin, without the accompanying discoloration. A slight blackish staining is all that is produced, and the ointment can even be employed in the scalp without markedly discoloring the hair, if applied cautiously. It is desirable, however, not to apply soap or alkalies at the same time, because this causes a more permanent and deeper stain.

Pyrogallallic acid cannot be used in extensively generalized psoriasis, when large surfaces are affected by the disease, without a certain amount of danger from absorption, as indicated by strangury and olive-green or tar-colored urinary secretions. With care, however, and the occasional suspension of the remedy for short periods, I believe this remedy could be employed even in universal psoriasis with good effect.

One more external application in psoriasis remains to be spoken of,—namely, naphthol. This drug, a derivative of coal-tar, was introduced into use several years ago by Kaposi, of Vienna, as a sort of substitute for carbolic acid. He recommends it very highly in psoriasis, in the form of ointment, about eighty grains to the ounce, and I have used it in this

and other strengths, and also in solutions in alcohol and oil, with fairly good effect.*

Naphthol is not so active in its effect as chrysarobin or pyrogallallic acid, but it is much more agreeable, and is, I think, peculiarly well adapted for employment upon such parts as are exposed to the view, as the face and hands. Like pyrogallallic acid, it must be used with caution over large surfaces, as absorption with toxic effects may be produced.

It remains to mention briefly two or three methods of application of these remedies which have recently been brought forward. The first of these is the treatment by medicated gelatin, which was introduced by Professor Pick, the well-known dermatologist of Prague. My attention was first drawn to this by a pamphlet which Professor Pick kindly sent me, in which he gave an account of his earlier experiments with medicated gelatins, but I have not as yet had an opportunity of testing this method of medication as I should desire. I may say, however, that the method does not seem to me calculated to prove convenient and popular in private practice. I had for some time been making some experiments in my service at the Polyclinic in the preparation of gelatins impregnated with chrysarobin and pyrogallallic acid, but without much satisfaction, when Dr. Charles L. Mitchell, the well-known pharmacist of this city, sent me some excellent preparations of his own, which seem to be perfectly adapted to the purpose for which they are intended. A bit of one of these gelatin sticks is cut off and placed in a water-bath, where it soon melts into a clear homogeneous fluid, which may then be applied to the lesions of the skin by means of a paint-brush. The advantages claimed are cleanliness and transparency. The coating of gelatin does not rub off on the clothes, and is therefore not so dirty as an unctuous application. A fresh coating can be painted on every day or two as the old layer wears off. The chief disadvantage of this method of treatment is that it requires apparatus which is not convenient to carry about, nor can the patient be trusted to employ it at his discretion. My own experience is that in psoriasis, at least, the gelatin applications are not active enough. I have not, however, used them with sufficient frequency to pronounce a positive opinion.

Recently a solution of chrysarobin in collodion has been recommended in the treatment of psoriasis by Dr. George H. Fox, of New York, and several dermatologists have confirmed his statements with regard to its efficacy. I have employed this preparation in one or two instances, but it has seemed to

* In a communication read before the American Dermatological Association last month, and published in the *American Journal of the Medical Sciences* for October, I have given the results of my experience in the use of naphthol in various diseases of the skin, psoriasis among the number. I may refer to that paper for further details as to the action of the drug in this disease.

me so much less active than the chrysarobin ointment that I have not been encouraged to continue its use. It has one great advantage over the gelatin applications, however, and that is that it can be applied extemporaneously and without the paraphernalia which must accompany the use of the gelatin.

A few weeks since, a pamphlet by Prof. Auspitz, of Vienna, reached me, in which that distinguished dermatologist recommended liquor gutta-perchæ as a vehicle for the application of chrysarobin. I at once obtained a ten per cent. solution, or rather emulsion, of chrysarobin in liquor gutta-perchæ, and, happening to have a case of psoriasis of the face and scalp under treatment, I gave some to the patient to apply once daily. The effect was so happy as to encourage me very much to hope that we have in this preparation the most convenient method of applying chrysarobin yet devised; and as chrysarobin is, after all, the most efficient local agent in the treatment of psoriasis as yet brought forward, I have no hesitation in urging the trial of this preparation on any one who may have a case of psoriasis under treatment. It is to be noted, however, that the same watch must be kept upon the skin for fear of exciting dermatitis as when the ointment is used. Only, when the liquor gutta-perchæ dries, which it does very quickly, there is little or no danger of rubbing the chrysarobin over the good skin, nor is there much danger, if any, of staining the clothing.

Dr. James C. Wilson read a paper entitled

NOTE ON HYDRARGYRUM FORMAMIDATUM.

Some accounts of this preparation have appeared in recent journals. Towards the close of last year, Prof. Liebreich proposed, in a meeting of the Berlin Medical Society, a new drug for the treatment of syphilis by the hypodermic method. Chemically this drug belongs to the amide group. Liebreich was led to use it from the fact that the ordinary amides of the body, of which urea is the principal one, are eliminated in an undecomposed state. When, however, the amide is in combination with a metal, decomposition occurs, and the metal is reduced and deposited. Liebreich found, by actual experiment, that this statement is true of mercury. It is supposed that the formamidated mercury, after hypodermic injection, undergoes decomposition, and that the metal mercury is set free in the tissues. The preparation is soluble in water, of neutral reaction, does not coagulate albumen, is not precipitated by caustic soda, and the presence of mercury can be demonstrated by potassium sulphide. It produces its effects very surely and rapidly. Liebreich regards it as the best remedy known for the hypodermic treatment of syphilis by mercury, as it is but little liable to excite local troubles or salivation. Later (*Medical Times and Gazette*, July 7, 1883) we find that Prof. Zeis-

sel, in Vienna, after trial of this remedy in fifteen cases of syphilis, was well satisfied with the results. In three of these cases salivation was produced. Some pain followed its injection, which was not, however, so severe as that following the hypodermic use of mercuric chloride. Twenty injections was the maximum number required to disperse the manifestations even in severe cases.

Dr. Schacht, of Berlin (*New Remedies*, September, 1883), writes as follows:

"Formamide is a colorless liquid, boiling at about 195° C., which can be distilled without decomposition only in vacuo. It is prepared by acting upon formate of ethyl by ammonia. When pure it is neutral, but easily becomes acid.

"If a *concentrated* solution of formamide be *boiled* with precipitated mercuric oxide, decomposition ensues, and metallic mercury is separated.

"On the other hand, if a *dilute* solution of formamide be *warmed* on the water-bath with precipitated mercuric oxide, a clear colorless solution results, in which soda (hydrate of sodium) produces *no* precipitate. Sulphide of ammonium, however, precipitates the mercury as sulphide, both from the formamide of mercury and from mercuric chloride. Solution of albumen is precipitated by the latter salt, but *not* by the formamide.

"Formamide of mercury is prepared in the following manner: ten to thirteen grammes of freshly precipitated, completely washed, and still moist mercuric oxide are gently warmed with a little water in a porcelain capsule, with gradual addition of ten grammes of formamide. As soon as solution has taken place, the resulting colorless liquid is filtered into a litre-flask, and the latter filled to the litre-mark with distilled water. Each cubic centimetre contains 0.01 gramme of mercury, which is the quantity representing *one* hypodermic dose. Formamide of mercury keeps well in brown-colored bottles, and should also be dispensed in these."

In a note from Vienna (*Medical News*, October 13, 1883), it is stated that Prof. Neumann is now trying hydrargyrum formamidatum on a large scale as an anti-syphilitic. It is used hypodermically in doses of one cubic centimetre. It acts with far greater efficacy upon the recent efflorescences than upon the later manifestations. Pain of great severity and active local inflammatory troubles have resulted in Neumann's cases.

The preparation which I exhibit, made by Merck, of Darmstadt, is a one per cent. aqueous solution, and the dose of it is from one-half to one ordinary hypodermic syringe-ful.

It has not been possible to obtain this drug in this city until the present time. I would be glad to place the specimen which is exhibited in the hands of any member of the Society who may desire to make a trial of it chemically.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

AT the semi-annual meeting of the Pathological Society of Philadelphia, held at the hall of the College of Physicians, Thursday evening, October 25, 1883, the President, Dr. Tyson, in the chair, Dr. Seiler read a paper on

THE PATHOLOGY OF PHTHISIS AND ITS LARYNGEAL COMPLICATIONS.

In this communication he gave his views regarding the pathology of tuberculosis and of phthisis and of the laryngeal complications of the two diseases. He defined tuberculosis as an auto-infectious disease, manifesting itself primarily by the production of minute neoplasms called miliary tubercles, which rapidly undergo retrograde metamorphosis, ending in caseation, leading directly to the dissemination of infectious material throughout the lymph-channels. This infectious material consists in cheesy matter due to scrofulous inflammation, which may remain encapsulated for a long period. He then described the histological characteristics of tubercles, and showed how they could produce consolidation of the lung-tissue by exciting secondary inflammation.

The lecturer then took up the consideration of the disease known as phthisis, and gave the following definition of it: "Phthisis is a progressive consolidation of the lung-tissue, due to a more or less localized inflammation, affecting primarily the apices, and undergoing retrograde metamorphosis; it is an inflammatory disease." He then gave a description of the pathological appearances as they are observed in the lung-tissue during the progress of the disease, and gave it as his opinion that the different forms and stages of phthisis, as they are described by many authors, are merely differences in the intensity and extent of the ulcerative process. As etiological factors he mentioned the various causes which produce a lowering of the vitality of the general system, thereby producing a predisposition on the part of the respiratory organs to chronic inflammation: among others he names heredity, peripheral nerve irritation, hypertrophic nasal catarrh, insufficient aëration of the blood, etc. An elevation of the vitality of the system at large would prevent an outbreak of the disease, or lead to recovery in cases where not too much lung-tissue had been destroyed. This elevation was to be produced by proper feeding and healthful exercise in the fresh air more than by the exhibition of drugs. On the other hand, tuberculosis is always fatal, and treatment was of no avail; but a great deal could be done to prevent the initial formation of the cheesy deposit by elevating the system of scrofulous patients early in life, thus preventing the outbreak of tuberculosis later.

The laryngeal complications of both dis-

eases were then considered in detail, and their differences pointed out. According to the lecturer, the laryngeal lesions never appear prior to the lung-disease in phthisis; they are characterized by a peculiar pallor of the mucous membrane, the tumefaction generally affects the posterior portions of the organ, and the ulcerations are shallow and have a tendency to spread on the surface. Tubercles, or cheesy deposits, are never found in the tissues of the larynx in uncomplicated phthisis. In tuberculosis, on the other hand, tubercular deposits have been found in the larynx prior to the lung-complication, the mucous membrane is of a lurid-red color, the tumefactions are more commonly observed in the anterior portions of the larynx, and the ulcerations are deeper, with raised edges, and often extensive destruction of tissue.

The paper closed with the remark that the indiscriminate use of the terms phthisis and tuberculosis, when speaking of lung-disease, in our literature, was calculated to mislead the student, and to make careful investigation into the pathology and etiology of these diseases extremely difficult, if not impossible.

Dr. J. C. WILSON, being called upon by the President, said that he had listened with interest to the reading of the paper. The field covered by the writer is too great to permit the points to be discussed in detail. Two points, however, appeared to warrant comment. First, Dr. Seiler had several times used the expression "tuberculous material not derived from the exterior." If he had understood the paper aright, Dr. Seiler had not indicated his views as to the nature and source of this "tuberculous material." Does he follow the older doctrine, that of Bayle? or has he some new opinion as to the etiology of tubercle? Secondly, Dr. Seiler failed to make clear his means of recognizing tubercle either clinically or in the laboratory. It would be of interest to know the writer's views upon this vexed question. In a recent work, Hamilton, of Aberdeen, again seeks to establish a histological criterion for tubercle,—the presence of giant cells under a peculiar arrangement. This pathologist points out two modes of degeneration for tubercle: 1, caseous; 2, fibroid. To the latter Dr. Seiler makes no allusion.

He thought, further, that the author of the paper had scarcely emphasized with sufficient force the presence of tubercle among the lesions in the various forms of phthisis, as seen in post-mortem examinations.

He heartily concurred in the hopeful views as to the curability of certain forms of chronic lung-disease when treatment is instituted at an early period. Nothing has exerted a more unfavorable influence upon the therapeutics of such diseases than the false view that the constitutional tuberculous diathesis invariably antedates the local lesions of pulmonary consumption.

Dr. F. P. HENRY remarked that Dr. Seiler's paper was so comprehensive that he found it impossible to refer to more than a few of the points contained in it. He was not inclined to draw so broad a line of distinction between that form of pulmonary disease in which milary nodules predominate and that in which the deposit is in larger caseous masses. Like Dr. Seiler, he was by no means convinced of the primary importance of the bacillus as a cause of tuberculosis, but was inclined, however, to attribute to it a prominent part in the production of the secondary symptoms of phthisis, those of systemic infection, which are largely septic in character. The symptoms of interference with oxidation caused by even extensive destruction of pulmonary tissue are subordinate to those of systemic infection caused by the absorption of the contents of cavities. The presence of the bacillus in the contents of these cavities is indispensable to the production of changes capable of producing this systemic infection. A small ulcerating cavity communicating with the absorbent vessels is more disastrous in its effects than a larger cavity shut out from the absorbents by a lining membrane or wall of fibroid tissue. He understood Dr. Seiler to deny the existence of the giant cell, and to make the statement that cross-sections of blood- and lymph-vessels have been mistaken for it. Dr. Henry did not agree with him in this view, but thought that the irregular contour of the giant cell and its granular protoplasm were sufficiently characteristic. Additional evidence of the existence of this cell was furnished by the experiment of introducing beneath the skin of an animal two thin glass covers, fastened together. In the interspace of the glasses giant cells have been found, and in such an experiment there can be no question of the cross-section of vessels. Dr. Seiler had several times referred to what is known in this city, and elsewhere, as Formad's theory of tuberculosis, which is that in certain animals predisposed to phthisis, and presumably in some human beings, the lymph-spaces are abnormally small, or, in other words, that in a given area of tissue there is to be found a greater number of endothelial cells than in non-strumous animals. Dr. Henry did not think this theory should be so extensively quoted until some more serious attempt had been made to establish or refute it. This might, he thought, be readily done by counting the cells in a given area of the tissue of strumous animals and comparing their number with that contained in the same area of tissue of non-strumous animals. He did not think any greater difficulty would be met with in this attempt than has been successfully encountered in the enumeration of the blood-cells.

Dr. BRUEN said that he believed in a hopeful prognosis in the early stages of many varieties of phthisis; even when the process

of phthisis is advanced, the management of cases is more successful when the lesions are localized; less advanced lesions are more grave when the lesions are widely disseminated. Dr. Bruen thought that it had been proved that phthisis could be produced by inhalation of inorganic irritating particles, especially if there was inherited predisposition to phthisis or an artificially-damaged constitution. May not bacterial elements be among the irritants capable of developing phthisis when inspired in large numbers? and he thought they might be even more capable of creating damage than inorganic materials, because they possessed the power of proliferation. Dr. Bruen agreed with Dr. Seiler in his views in the main, and considered his paper most instructive and interesting.

Dr. MILLS thought it worth while to note the frequent occurrence of tuberculosis among those afflicted with chronic nervous and mental diseases. At the institutions for the feeble-minded and insane, phthisis or tuberculosis is a common cause of death. This fact, he thought, would lend support to the views of Formad rather than to those of Koch.

Dr. J. T. ESKRIDGE had observed that some who had participated in the discussion referred to the views of the pathology of tuberculosis expressed in the paper of the evening and to those entertained by Dr. Formad in order to prove the same thing. He regarded the theories of each of these men as widely different. If tuberculosis is the result of inflammation in a person whose lymph-channels are abnormally narrow, as claimed by the latter, he could not see that phthisis differed from tuberculosis, as maintained by the former. In regard to tuberculosis being frequently developed in chronic diseases of the brain and cord throwing light on the pathology of the former, he thought the association of these diseases proved nothing more than that a prolonged period of lowered functions of the body was a favorable condition for the development of tuberculosis. He confessed that he did not know what to believe with reference to the pathology of tuberculosis; enough, to his mind, had not been proved to establish firmly any theory yet advanced so that it might be accepted as positive fact. Dr. Eskridge agreed with Dr. Shakespeare in demanding more pathological investigation, following the clinical observation of the disease, before he could accept any view as positive of the pathology of tuberculosis. Dr. Eskridge called attention to the fact that many of the best clinical observers of large experience, such as Flint, Da Costa, and Hughes Bennett, considered tuberculosis and phthisis to be identical.

Dr. DAVIS asked Dr. Seiler if he taught that tubercle was caused by a caseous focus. He was answered, Yes. He continued: It is important to know whether this is the case or not, as the German surgeons excise caseous

glands, not so much for the deformity they produce as to obviate the liability to general infection. Would Dr. Seiler sanction this practice? As regards the possibility of cure, he believed, with Koster, Billroth, and Koenig, that tubercle is a local affection, and not a general disease. He had seen as marked tuberculosis in the knee as in the lung, the miliary tubercles being within an eighth or a quarter of an inch of each other. He has also seen tumor albus of the knee recover without operation. If the tuberculosis can get well in the knee, he believed that it can in some cases get well in the lung also.

Dr. SEILER, after thanking the Society for the interest shown in his paper, said that, as most of the questions submitted to him had been already answered in his communication, he would not reply in detail, owing to the lateness of the hour.

A vote of thanks was passed by the Society to Dr. Seiler for his interesting communication.

A social meeting was held after the close of the business of the evening.

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting of the Academy was held, November 1, 1883, Fordyce Barker, M.D., LL.D., President, in the chair.

Dr. T. H. BURCHARD read a biographical sketch of the late Dr. Frederick D. Lente, of Cold Springs, New York. He was born in North Carolina in 1823, took the degree of A.M. from the University of North Carolina, graduated from the medical department of the University of the City of New York in 1849, and had since practised medicine in New York, at Cold Springs, Saratoga, and in Florida, the state of his health necessitating from time to time a change of locality. He once held a professorship in the University of the City of New York. Dr. Burchard described his lamented friend as conscientious, unpretentious, gentle, an earnest student, of active mind, thorough and accurate as a diagnostician, and self-sacrificing in his devotion to the interests of his patients. He died of cerebro-spinal meningitis.

ON THE RAPID EVACUATION OF STONE FROM THE BLADDER AFTER CRUSHING, WITH PRESENTATION OF A NEW AND SIMPLIFIED EVACUATOR.

Dr. FESSENDEN NOTT OTIS read a paper with this title. Dr. Otis reviewed the subject of evacuation of the bladder after crushing of stone at some length, referring to early instruments invented by Sir Philip Crampton, Clover, and others, and quoting from the writings of Dr. Bigelow, of Boston, whose later and more-perfected instrument was the one which he, Dr. Otis, had used with entire satisfaction until recently, when he had the

pleasure of constructing one more simple in its make-up, more easily portable, less expensive, and free from certain imperfections which had been referred to that of Dr. Bigelow. The principal objection to the earlier inventions related perhaps less to the evacuator itself than to the size of the tube employed: it was then taught that the normal size of the urethra was equal only to twenty-one millimetres in circumference. It was now recognized that the larger the tube employed, consistent with the size of the urethra, the more readily would evacuation be effected. Dr. Otis referred to his published writings, going to prove that the normal male urethra varied in size from that of thirty-two millimetres to forty and more in circumference, and that the size of the canal bore a certain ratio to the circumference of the penis. In the numerous measurements which he had made, he had never found a single case in which the normal male urethra fell below twenty-eight millimetres, and he never hesitated on finding a constriction below this degree to look upon it as abnormal, and before proceeding to perform lithopaxy to enlarge the canal by division or by dilatation, as the case might demand. It was specially important that a narrow meatus should be divided, rather than allow one's self to be led to the use of a small-sized evacuating tube with its accompanying disadvantages. The wounds produced by division or division should be allowed to heal before proceeding with the principal operation. The difference in the working value of the large- and small-sized tube was illustrated in two experiments, in which, other things being exactly equal, a tube thirty millimetres in circumference transferred three hundred grains of crushed coral in thirty seconds, while one of twenty-seven millimetres transferred only two hundred and eighty grains in the same time. In the case of the old man with enlarged prostate, it was safer to use a smaller tube, rather than run the risk of introducing one of larger size. Dr. Otis traced the successive steps in inventions by Dr. Bigelow, Sir William Thompson, and others, in attempts to construct an instrument by which rapid evacuation could be effected, which would avoid introduction of air into the bladder and return of fragments of stone during the operation; which, in short, would permit of the most rapid evacuation with the best possible results.

The instrument which Dr. Otis then presented consisted of a hollow glass globe; about two inches in diameter, into one side of which, and projecting upward, was a metallic tube connected outwardly with a rubber air-cavity; into the other side, and projecting downward, was another metallic tube, connected with the tube entering the bladder. The receptacle for the particles of stone consisted of a small glass vessel attached to the globe below. The globe being filled with water, either by suction force through the tube, or by pouring in at the

connection with the receiver, the pressure upon the rubber air-bag forced the fluid into the bladder, which returned with fragments of stone when the bag was again allowed to expand. The relation of the two metallic tubes in the globe, one opening upward, and the other, carrying the stone, downward, prevented any return of fragments, or, indeed, any agitation of the fluid in the receiver below. The amount of water in the bladder could be augmented, if desired, by turning the globe over and pouring in at the connection with the fragment-receiver. The globe could be protected by a light framework with some additional cost. The instrument worked with great satisfaction, was easily portable, cost but half as much as that of Bigelow, was free from certain objections which had been offered to the latter, and the operator was enabled to see the progress being made through the glass globe and receiver. He also employed a tube a little more curved at the end than that used by Bigelow, by which it was rendered easier of introduction and was less liable to become clogged with mucus.

Dr. E. L. KEYES opened the discussion, saying that he had only seen Dr. Otis's instrument for the first time to-day, had not had an opportunity to employ it, and was therefore unable to speak with regard to its practical working; it certainly, however, appeared very simple, and promised to be of the greatest service. It attested the great ingenuity displayed by the inventor on previous occasions. He had used Bigelow's improved apparatus, and had found that it worked very satisfactorily indeed; the objection which had been raised to it, that the screen was liable to become clogged with mucus, had not held true in his experience. Dr. Otis had referred to the history of tolerance of the bladder to surgical manipulation, in which it was stated that it had been established before Dr. Bigelow dwelt upon the fact; Dr. Keyes said that this tolerance was well known to the first inventors of vesical evacuators. He also stated that the inventions of Clover, and others about his time, illustrated in the diagrams by Dr. Otis, were not intended for use upon the healthy viscus, but in its diseased state. Concerning the normal calibre of the male urethra, he did not think it best to form a high and fixed ideal on this subject, and insist upon dividing or dilating every urethra which did not conform to that standard. In general, the larger the tube employed for evacuation, the more easily would the fragments be removed, but he believed that we should not seek to introduce too large a tube, lest damage be done to the urethra; this was specially the case in the aged with enlarged prostate. He mentioned a case in which he had operated, using a smaller-sized tube with safety, and the patient was afterwards operated upon by another physician, who introduced a tube of large size with sad results. He believed that the ma-

jority of surgeons employed a tube of smaller size than that recommended by Dr. Otis, not but what the larger size in itself possessed certain advantages, but because they feared, possibly without reason, doing damage to the urethra. The success of the operation for evacuation depended upon a happy combination of the several points involved in the instrument used and of the steps of procedure, rather than upon the use of a tube of a particular size, or other single fact or detail.

Dr. OTIS closed the discussion by correcting certain theoretical objections to the instrument which had been raised by Dr. Keyes.

REVIEWS AND BOOK NOTICES.

A PRACTICAL TREATISE ON MATERIA MEDICA AND THERAPEUTICS. By ROBERTS BARTHOLOW, M.D., Professor of Materia Medica and Therapeutics in the Jefferson Medical College of Philadelphia, etc. Fifth Edition, revised and enlarged. New York, D. Appleton & Co., 1884. 8vo, pp. 738.

Professor Bartholow has special talent for condensation, combined with a comprehensive knowledge of his subject, and a power of direct expression. That this combination is gratefully appreciated by the overworked American student and the no less overworked physician has been fully demonstrated by the remarkable demand for this work on therapeutics, which has now attained its fifth edition in less than seven years. On account of its convenience for reference and completeness, it has been adopted as a text-book in many of our medical colleges. The principal features of this treatise are now so well known that they need not be here specified: it is only necessary to quote from the preface that the present edition has been carefully corrected, and changed so as to correspond with the last revision of the United States Pharmacopœia, and that the opportunity has been embraced to incorporate some recent improvements in the science and art of therapeutics, which has somewhat increased the size of the work.

Among the sections considered worthy of special mention we might instance those on Electricity, Aliments, the shorter discussions of Massage, Air, Water, Hydrotherapy, and the various mineral springs of this country and Europe; while many of the newer remedies, convallaria, kairin, resorcin, curara, picrotoxin, muscarin, etc., receive ample consideration.

A few errors have apparently escaped the vigilant eye of the author. For instance, *tinctura aconiti radidis* (p. 597) should be *tinctura aconiti* according to the Pharmacopœia. *Chrysarobin* (U.S.P.), although officinal, does not appear in the work, nor can

Goa powder be found; chrysophanic acid is merely mentioned (on p. 639) as a constituent of rhubarb; its most important application in the treatment of psoriasis is not referred to. The author apparently considers carminatives of such slight importance that he has totally ignored such old-time friends as anise, cardamom, fennel, and ginger; and chamomile, both the English (*Anthemis*) and the German (*Matricaria*) variety, is also unaccountably missing; this is true likewise of musk, castoreum, cassia, juglans, tar, pitch, *sapo viridis*, wax, spermaceti, resin, and a number of officinal preparations which we think should appear in a text-book on *materia medica* (*i.e.*, *aqua ammoniæ fortior*, *chartæ potassii nitratis*, etc.). The very important fact of the great variation in strength between the French, German, and English makes of aconitine is not stated; a caution should here be given. An *aromatic* syrup of rhubarb should be included in the list as officinal under Rheum, in addition to the simple syrup (p. 639). For the sake of the student, it would have been proper to give the pharmacopœial definition in a few places where apparently without special reason it has been omitted (see Galla, p. 296; *Picrotoxinum*, 405; *Thymol*, 356; *Alum*, 292, etc.); and it would also have prevented mistake if the fact had been plainly indicated that these remedies are officinal. Among the non-officinal remedies worthy of being considered, but which we do not find, are pyrogallac acid, sodium ethylate, boroglyceride, jequirity, coto bark, and the new oleates of quinia, morphia, etc. The reference to sewer gas (p. 79) is liable to be misunderstood by the student, who might be led, from the context, to consider it as a definite chemical compound, or an elementary substance, which would be the reverse of truth, and the opposite, no doubt, of the author's views. He would, moreover, be inclined to entertain a doubt of the correctness of the statement (p. 77) that even the electric light could bring into the view of the otherwise unaided eye minute particles that are "extra-microscopic," including disease-germs; while the instructions given for making a flaxseed-poultice (p. 700) are scarcely such as would satisfy the requirements of the elder Professor Gross. The young practitioner, we fear, would hardly be able to justify himself before the coroner in case of an unfortunate result if he should follow the recommendation to give such large doses of *veratrum viride* as "3ss of the fluid extract every fifteen minutes, until nausea or vomiting ensues," even though pronounced invaluable in puerperal convulsions (p. 606). He would find it much safer to begin with a smaller quantity. (The proper dose is given on p. 602 as $\mathfrak{ij}$ ij-v.)

The instrument used by Dr. Mortimer Granville is not a "*percutier*" (p. 84), but a "*percuteur*" for applying massage to a nerve-

trunk in the treatment of neuralgia. As the Pharmacopœia uses the word "officinal" to designate the titles of those articles of medical use which are directed to be kept in the shops, we can scarcely regard the word "official" as used by Dr. Bartholow as its equivalent. Every direction or process authorized by the Committee on Revision must be considered as official, but the term "official" is the only correct one to apply to the approved *materia medica*.

We do not make these corrections in a carpentering spirit, but merely to aid the author in still further improving a most useful text-book both for students and practitioners. F. W.

GLEANINGS FROM EXCHANGES.

FORCIBLE DILATATION OF THE CARDIAC AND PYLORIC ORIFICES OF THE STOMACH.—The London *Lancet* of September 1, 1883, contains a brief report of two operations performed by Prof. Pietro Loreto for the relief of cardiac and pyloric stenosis by forcible dilatation, a full report of which by Dr. A. Albertini is to be found in the *Gazzetta degli Ospitali* of August 18. The operation upon the pylorus was performed by the fingers, and was the fourth one of this kind made by Professor Loreto. The patient—a woman, æt. 34—had suffered for three years from an affection of the stomach, accompanied by vomiting and nausea, and was so emaciated as to resemble a skeleton. The stenosis was diagnosed as inflammatory in character. The operation of opening the abdomen and stomach, dilating the orifice, and closing the wound occupied thirty minutes. Adhesions existed between the stomach and liver, intestines and omentum. Several arteries required ligation. The dressings were removed on the tenth day, and the wound was found healed. No constitutional disturbance followed the operation. The patient left the hospital at the end of a month perfectly cured.

On July 9, Professor Loreto performed an operation of forcible dilatation upon the cardiac orifice of a patient, a woman, who had suffered four years from symptoms of cardiac constriction. Continuous vomiting and incessant pain had produced extreme emaciation. In this operation a metallic dilator was employed to widen the contracted orifice. As in the first operation, the wound healed by first intention and without constitutional disturbance; vomiting ceased, and the patient regained flesh rapidly, increasing fourteen pounds in weight within six weeks.

The promptness with which union of the wounds occurred, and the entire absence of constitutional disturbance, invite attention. It is presumed that great care was exercised in surrounding the patient with the best hygienic

conditions, in the preliminary preparation of the patient, in the employment of antiseptic precautions, and in careful after-treatment. It would seem that successful results after such operations must depend upon all of these precautions.

According to the statement in the *Lancet*, Professor Loreto has operated in five cases. So far as we know, no report has been made of the condition of the patient first operated upon. It is quite manifest that great interest centres in the permanent character of the relief afforded by the operation, and with regard to this question time alone can decide. Another point of interest relates to the application of this operation to cases of malignant diseases, which, as a rule, involve the pyloric more frequently than the cardiac orifice. In certain cases where ulceration is absent, forcible dilatation might afford temporary relief, but an important question suggests itself, whether it would not be better surgery to perform, in all cases of malignant disease, the radical operation of resection of the organ, as has been successfully done. The operation of opening the stomach is too grave in character to be done as simply a palliative measure.

No details of the operative procedures are given in the first operation. In the second case it is stated that the incision in the abdominal wall was almost horizontal and just below the ensiform cartilage. The stomach was freely opened below the small curvature.

From the results in these two cases it would appear that the stomach does not resent operative interference of rather severe character, and that the procedure of forcible dilatation is sufficient to relieve a condition of stenosis which had given rise to very grave symptoms and conditions which foreshadowed fatal terminations. The question which remains to be solved is in regard to the permanent character of the relief afforded by the operation.

MISCELLANY.

INVESTIGATION INTO THE CAUSE OF THE YELLOW FEVER AT PENSACOLA.—By order of the Secretary of the Navy, a court of inquiry has investigated the circumstances connected with or which led to the recent outbreak of yellow fever at the United States Navy-Yard at Pensacola, Florida. After duly considering the facts, the court arrived at the following conclusions:

"First. 'As to the circumstances which led to the outbreak of the fever.'

"Having reviewed the evidence, we are now of opinion that the epidemic of yellow fever, now near its close, prevailing on the Naval Reserve, may be traceable to one or more of four origins,—viz.:

"1st. Possible infection from Pensacola by communication of persons, and by articles brought from that city.

"2d. Articles in Equipment and Steam-Engineering Storehouse possibly infected in former epidemics.

"3d. Possible infection of marine barracks since 1875.

"4th. Probable infection from the ballast used and handled at Fort McRae jetties by men who lived in and visited the villages of Warrington and Woolsey weekly and semi-weekly in their working clothes.

"Second. 'Whether or not proper measures were adopted to prevent the introduction of yellow fever into the navy-yard.'

"The first case of yellow fever having appeared in the marine barracks within the navy-yard previous to the death of the first case in Warrington, and not finally diagnosed and decided to be yellow fever until three days after attack, any precautions that could have been taken at that time to prevent the introduction of the disease into the navy-yard would have been unavailing, as the marine guard and the surgeon himself were already infected."

DAMAGES FOR ACCIDENTS DURING ANÆSTHESIA.—A suit brought against a dentist in New York City for negligence in allowing a piece of a tooth to drop into a patient's throat, which, after causing the patient to suffer with a cough, was expectorated at the end of a month, was recently decided against the defendant, who was obliged to pay five hundred dollars damages. The case was appealed, but the judgment was sustained. This recalls a case of a boy who died while under the influence of nitrous oxide gas, being suffocated by a molar tooth which slipped out of the forceps and became impacted in the larynx. In such cases, a dentist should be both competent and willing to perform tracheotomy, for the patient will generally die of suffocation before a surgeon can be summoned.

QUADRUPLETS.—*The Canadian Practitioner* contains an account of four living children at a birth, two boys and two girls, with but a single placenta. The mother was a small woman, weighing one hundred pounds, 38 years old, and had nothing unusual in three previous confinements. The father is 41 years of age, weighs one hundred and sixty-nine pounds, and is a strong, healthy, and robust man. He is reported as doing as well as could be expected.

A CONSISTENT NO-CODE ADVOCATE.—Dr. H. H. Kane, of New York, having taken to advertising and dealing in a nostrum for the treatment of the opium habit, has had his name dropped from the roll of members of the New York County Medical Society.

CORRECTIONS IN THE PHARMACOPŒIA.—A list of the changes and corrections made since the publication of the last edition of the *Pharmacopœia* can be had by enclosing a stamp to the publishers, Messrs. William Wood & Co., New York.

A MARTYR TO SCIENCE.—M. Thuillier, a scientist, and member of the French Cholera Commission sent to Egypt under the direction of M. Pasteur to investigate the cause or causes of the cholera prevailing there, has died from the disease contracted in the cholera hospital in Alexandria.

THE IOWA STATE MEDICAL REPORTER is the title of a monthly medical journal recently issued,—the only medical journal published in the State. It is ably edited, and its contents are interesting and largely original. Price, \$2 per year.

THE MEDICAL STUDENT is a new monthly journal issued in New York for circulation among medical students. It is well printed, and has an attractive appearance. The first number contains a letter from J. Milner Fothergill, of London.

OBITUARY.

DEATH OF DR. J. MARION SIMS, OF NEW YORK.

Dr. J. Marion Sims died of heart-disease at his home in New York City, November 13. He had retired, apparently in his usual health, the evening before. Early in the morning he conversed with his wife. Shortly after she observed that something was wrong, and immediately summoned his son. An examination showed that the doctor was dead. Dr. Sims was to have sailed for Europe on the 17th instant.

James Marion Sims, M.D., was born in Lancaster District, South Carolina, the 25th of January, 1813. In 1832 he was graduated from the South Carolina College at Columbia. He then studied medicine in Charleston, S.C., and at the Jefferson Medical College in this city, from which he was graduated in 1835. In 1836 he settled at Montgomery, Ala., and it was there he began to build up the reputation for daring and skilful surgery which has since extended throughout the civilized world. In 1845 he attracted attention to his new theory of the nature and origin of trismus nascentium, in regard to which he published a series of articles in the *American Journal of the Medical Sciences* three years later.

In 1845, also, he became especially interested in the subject of vesico-vaginal fistula. He supported a private hospital in Montgomery, Ala., for the treatment of this disease, at his own expense, and after four years was successful in his endeavors. He had introduced the use of sutures of silver wire, instead of the silken and other sutures formerly in general use, and he afterwards extended the employment of metallic sutures to all departments of general surgery. He also perfected all the mechanical appliances required for the successful treatment of vesico-vaginal fistula, and invented the famous "Sims speculum." His health failing in 1850, a change of climate was thought desirable, and in 1853 he removed from Alabama to New York City.

Being anxious to establish in the latter city a large hospital especially for the treatment of the diseases of women, he delivered an address for this object in May, 1854, before a meeting of the medical profession. He impressed his views on his hearers, and a Woman's Hospital Association was soon formed, under the management of many of the best-known ladies in the city. In 1861 Dr. Sims went to Europe, whither his fame as a surgeon had preceded him, and where he received great attention from members of his profession. He was invited to perform operations before Nelaton, Baron Larrey, Velpeau, and all the other prominent surgeons of Paris. In 1864 the French Government conferred upon him the order of Knight of the Legion of Honor. He accepted a special invitation from M. Deroubaix, the surgeon of the King of the Belgians, to visit Brussels and operate in the hospitals there, before the members of the Faculty. He created so marked an impression by the manifestations of his skill and the new ideas which he imparted that the Belgian professors immediately elected him a Corresponding Fellow of the Imperial Academy of Medicine, and also recommended his name to the Belgian Government for the order of Leopold I. The decoration was withheld at the time, but was conferred upon Dr. Sims during a visit to Europe a few years ago.

In 1870, after a hard struggle, he succeeded in organizing in Paris the Anglo-American Ambulance Corps, which did such efficient service. As a surgeon, the delicacy of his touch, the keenness of his perception, and the bent of his mind combined to make him especially fitted to treat the diseases of women. Throughout his life he kept enlarging the list of possible operations, so that his labors have rendered it possible for many women to benefit, with comparatively little risk, from operations which were formerly considered altogether impossible, or so hazardous as to be practically out of the question. His "Clinical Notes," published in 1866, is a standard work, and has been translated into French and German. On the 21st of December, 1836, he married Eliza Theresa, daughter of Dr. Bartlett Jones, of Lancaster, South Carolina. He leaves four daughters and two sons. One of his daughters is the wife of Dr. Thomas T. Pratt, formerly of Alabama, but now of Paris. His sons are Mr. W. Marion Sims, and Dr. H. Marion Sims, of New York City.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM OCTOBER 27 TO NOVEMBER 10, 1883.

BACHE, DALLAS, MAJOR AND SURGEON.—Paragraph 1, S. O. 238, A. G. O., October 18, 1883, assigning him to duty at Willet's Point, New York, revoked. Paragraph 2, S. O. 252, A. G. O., November 3, 1883.

McKEE, JAMES C., MAJOR AND SURGEON.—Relieved from duty in the Department of California, and assigned to duty as Medical Director Department of the Columbia. Paragraph 5, S. O. 249, A. G. O., October 31, 1883.

PRICE, CURTIS E., CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty at Fort Custer, M. T. Paragraph 1, S. O. 187, Department of Dakota, October 25, 1883.

STERNBERG, GEORGE N., MAJOR AND SURGEON.—Leave of absence granted October 4, 1883, extended one month. Paragraph 4, S. O. 255, A. G. O., November 7, 1883.

VICKERY, R. S., MAJOR AND SURGEON.—Assigned to duty at Fort Townsend, W. T. Paragraph 3, S. O. 149, Department of the Columbia, October 29, 1883.

WOLVERTON, WILLIAM D., MAJOR AND SURGEON.—Granted leave of absence for one month. Paragraph 6, S. O. 201, Department of the East, October 24, 1883.

MERRILL, J. C., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for one month. Paragraph 7, S. O. 201, Department of the East, October 24, 1883.

PATZKI, J. H., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for three months, on surgeon's certificate of disability. Paragraph 6, S. O. 254, A. G. O., November 6, 1883.

WILSON, GEORGE F., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to temporary duty at Fort Townsend, W. T. Paragraph 2, S. O. 149, Department of the Columbia, October 29, 1883.

OWEN, W. O., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Relieved from duty at Vancouver Barracks, W. T., and assigned to duty at Fort Stevens, Oregon. Paragraph 2, S. O. 148, Department of the Columbia, October 26, 1883.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY FROM OCTOBER 27 TO NOVEMBER 3, 1883.

The orders of Medical Inspector A. C. GORGAS to the Naval Hospital, Mare Island, California, revoked, and to remain at Naval Hospital, Chelsea, Massachusetts.

Medical Inspector SOMERSET ROBINSON to the Naval Hospital, Mare Island, California.

Surgeon F. M. DEARBORNE to appear before the Retiring Board November 5.

Medical Director A. L. GIHON and Medical Inspector A. HUDSON to represent the Navy at the meeting of the American Public Health Association at Detroit, Michigan, November 13.

Assistant-Surgeon J. M. EDGAR from the receiving-ship "St. Louis," at League Island, Pennsylvania, to the receiving-ship "Wabash," at Boston, Massachusetts.

P. A. Surgeon A. A. AUSTIN to the receiving-ship "St. Louis," at League Island, Pennsylvania.

There were no changes during the week ending November 10.

PHILADELPHIA MEDICAL TIMES.

PHILADELPHIA, DECEMBER 1, 1883.

ORIGINAL LECTURES.

AN ADDRESS BEFORE THE MEDICO-LEGAL SOCIETY OF PHILADELPHIA.

BY JOHN J. REESE, M.D.,

Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania.

MR. PRESIDENT, AND GENTLEMEN OF THE MEDICO-LEGAL SOCIETY OF PHILADELPHIA,—I have been honored with an invitation to make you an address on this evening, which I understand is the opening of your annual session. It has afforded me much pleasure to accept this invitation, for two reasons: first, because it enables me to express to you my cordial sympathy in this movement on your part to inaugurate a Society whose object is to interest the two great professions of Medicine and Law in that most important, but hitherto much-neglected, science of *Legal Medicine*; and, secondly, because I thought that possibly I might be able to suggest to my medical brethren who are members of this Society, some few practical hints pertaining to the subject, which might prove useful in their future development of the science.

I may embrace the occasion to remark that it has seemed to many of us a matter of surprise, that in the city of Philadelphia, which may rightly be termed the mother of American medicine and the nurse of American medical schools, no attention whatever has been given to Medical Jurisprudence as a science, by either of the two professions of law or medicine, until within comparatively few years—very partially in Medicine only, but not at all in Law up to the present day.

I find, in looking over the literature of this subject, that the first public teacher of legal medicine in this country was Dr. James S. Stringham, of New York, who lectured upon it in Columbia College in the year 1804. In 1815, Dr. T. R. Beck was appointed Professor of Medical Jurisprudence in the Western Medical College; and, not long after, Dr. Walter Channing was elected to the chair of Midwifery and Medical Jurisprudence (a rather curious association of subjects), in Harvard University. Since that period, most of the leading medical schools of our country, and even some of the second and third rate

schools, have made this branch a part of their regular systematic course of instruction, though, it must be confessed, a very small and insignificant part, inasmuch as it is usually tacked on to some other branch, like an unnatural excrescence, apparently to swell the size of the programme, and thus bid for popular patronage. I need hardly say that the amount of medico-legal instruction given in all such schools is exceedingly meagre.

In the year 1810, Dr. Benjamin Rush delivered an introductory lecture to his course on the Practice of Medicine in the University of Pennsylvania, in which he dwelt in an eloquent and impressive manner on the importance of the study of medical jurisprudence. But no further attention seems to have been bestowed upon the subject by the authorities of that institution for more than fifty years, when the liberality of one of Rush's most distinguished successors in the chair of Practice, the late Emeritus Professor Dr. George B. Wood, endowed a chair of Medical Jurisprudence and Toxicology, along with several other chairs, constituting what is known as the Auxiliary Faculty of Medicine in the University of Pennsylvania. This, I say, was the very first attempt ever made in this city even to recognize the science of medical jurisprudence. But even this was only a very partial recognition, inasmuch as the study was not made obligatory upon the student, nor was it regarded as essential to his graduation in medicine.

I remarked a few moments ago, that the legal profession in our city had made absolutely no provision whatever for instructing the law-students in the science of medical jurisprudence. This must certainly strike you as a remarkable and somewhat anomalous circumstance. It is, however, true that soon after the establishment by Dr. Wood of this chair in the medical department of the University, in 1865, the trustees created a professorship of medical jurisprudence in the law department of that institution. But, singular to relate, while the programme of the law school embraces (on the published catalogue) a professorship of medical jurisprudence along with the four other law-professorships, the students are quietly informed that attendance on the former course, although recommended, is not obligatory, and that they will not be examined thereon for gradua-

tion in law! As a matter of course, such an arrangement makes the medical-jurisprudence professorship a dead letter, and has proved a most effectual extinguisher to any attempt to instruct our rising generation of lawyers in the science of legal medicine. Yet I presume that the average common-sense mind among us, and among the public generally, will fail to comprehend by what species of intuition the Philadelphia law-student is to acquire a knowledge of *criminal law* without ever having learned the principles of medical jurisprudence! The simple truth of the matter is that our law-students are encouraged (so it would appear) to ignore criminal law altogether. It has been quite too much the fashion for our young barristers to look down with contempt upon this branch of their profession, as savoring too much of the quarter-sessions' practice. This, be it remarked, is a traditional prejudice, peculiar, I incline to think, to Philadelphia; but its absurdity is too evident to require comment.

I have ventured these remarks, gentlemen, because I am probably better aware than you can be, of the stubborn nature of the soil which you will have to overcome in our community before you can hope to gather much of a harvest in medico-legal research. I should greatly rejoice to see your Society taking a very decided stand in this matter, exciting the interest that it deserves, and that ought to be so spontaneous, in both the great professions of law and medicine in our city, and enlisting in its support and co-operation the best talent of both professions. In our sister city of New York, such a society has been in active operation for a number of years; it numbers among its members some of the brightest physicians and lawyers of that city, and its published papers contain most valuable material for the medico-legal student. Certainly, Philadelphia ought not to be lagging behind in this matter; nevertheless, I must in all sincerity say to you that we can hope for but little success, until we succeed in breaking through the pretty thick crust of indifference, not to say apathy and opposition, that we may have to encounter from both the professions.

Let me now turn to something more directly bearing on the occasion of my meeting you this evening, viz., to venture to throw out a few practical hints in relation to the cultivation of the study of medical jurisprudence. Let us first clearly

understand the meaning of the term. Medical jurisprudence, or, as it is sometimes named, legal or forensic medicine, is the science that teaches the application of medicine to the purposes of the law. The grand object of the law is the discovery of truth. In order to attain this object it lays under contribution every department of knowledge,—medicine among the rest. A superficial observer is surprised to discover the intimate relationship subsisting between the two sciences of medicine and law. How many doubtful questions are solved in a court of justice solely by medical jurisprudence! Think only of the numerous cases of sudden death, occurring under suspicious circumstances; of persons found dead; of real or alleged insanity; of personal identity; of infanticide and criminal abortion, and numerous other cases depending for their final settlement mainly, if not exclusively, upon medical testimony. In fact, every branch of medicine may be summoned to contribute its quota as occasion may arise. Thus, is it a trial for murder in which the proof of the crime is closely connected with certain marks of violence discovered on the dead body? at once the skill of the anatomist and surgeon, as also that of the pathologist, comes into requisition. Is it a trial for criminal abortion, infanticide, or rape? here immediately the knowledge of the obstetrician becomes indispensable. Is it a trial for poisoning? here the skill and experience of the chemist and toxicologist, and, it may be, of the botanist, will become absolutely necessary. And when the case is one involving the complex questions of insanity,—as in determining the validity of a will, or the criminal responsibility of a homicide,—who can give the required information, or enlighten the court and jury, save he who has mastered the complex and subtle study of the mental and psychological functions? It were easy to multiply illustrations of this nature, but the above will suffice to indicate the intimate connections subsisting between medicine and law.

It is sometimes the fashion to depreciate the study of medical jurisprudence, as being of no actual practical value to the student or the physician,—I need not say the lawyer also; but this mistake must surely arise from the grossest ignorance. It were easy to show the falsity of such an idea. One of the first cases to which the

young physician may be called, after settling down to practice, and one to which any of ourselves is liable any moment to be summoned, may be a case involving a knowledge of this very science. For instance, it may be a case of gunshot wound, or of dangerous injury from some other cause, or from the administration of poison. As a skilful physician or surgeon, he, of course, immediately addresses himself to the care of the patient. But should there be any suspicious circumstances connected with the case, and especially if the issue should be fatal, he must not for a moment suppose that his duties end there; far from it. His profession and his position both require him to go into all the circumstances of the case. Were these injuries, or this poisoning, homicidal, suicidal, or accidental? If death resulted from a pistol or rifle-ball, what were its direction and distance? If it is a poison case, then did the death really result from the poison, and, if so, what sort of poison? or what latent disease may have been the real cause of death? Or, is a lifeless body discovered in the water,—was the death here really caused by drowning, or was a murder first committed and the corpse subsequently thrown into the water in order to elude suspicion? A thousand questions of this sort are ready to confront the physician in his daily experience; and, unless he has added to his mere medical knowledge an understanding of the principles of legal medicine, he may find himself in an unpleasant predicament, since he will be compelled to assume the functions of the legal physician, when he subsequently appears in court, to give his medical testimony.

I trust I may be pardoned if I put this subject before you in a still more home-like manner, and try to draw a picture, the counterpart of which some of my hearers may but too readily recognize. Let me suppose a young physician, comfortably settled in practice, with everything around him prosperous and happy. Devoted to his profession and well instructed in all its details, he is anxiously looking out for cases on which to exercise his skill and dexterity. He is suddenly summoned to a case of fracture of the thigh, or, it may be, a dislocation of the wrist-joint. With promptitude he repairs to the suffering patient, and puts in practice the well-remembered instructions of the class-room and clinic. He applies his splints and bandages after

the most approved methods, he soothes the resulting inflammation, he closely watches for unfavorable symptoms, and he very naturally anticipates a favorable termination of the case; when, unhappily, either owing to some vice in the patient's constitution, some previous bad habits of life, some climatic or hygienic influence, or some of the other thousand contingencies over which the physician can have no control, the patient is attacked with erysipelas or pyæmia, which spreads with frightful rapidity; and after bringing him to the brink of the grave he slowly recovers, but, to the doctor's infinite chagrin and disappointment, with a shortened limb, or with a stiffened joint. And now comes the trouble. It not infrequently happens that the patient who has received so much kindness and skilful attention, turns upon his benefactor, and rewards him by instituting against him a suit-at-law for alleged malpractice, laying his damages at many thousand dollars. What a monstrous wrong! What flagrant injustice! you will exclaim. So, indeed, it is; but so a jury will not always decide; and a ruinous verdict may be the termination of the unhappy affair. Gentlemen, let me tell you, this is no mere fancy sketch; but it has been realized, possibly, in the experience of some whom I now address.

Now, what is the remedy for this evil? Mere professional sympathy on the part of his medical brethren will not meet it. You cannot reach it by mere enactments of law. The only effectual method of relief, I believe, is to elevate the standard of medico-legal knowledge in the professions of both medicine and law. Let the physician fully understand his medico-legal rights, as well as the principles and practice of medical jurisprudence; and he need then have no fear to encounter such obstacles as we have been considering.

But there is another aspect of the case quite as practical, and quite as important to the medical practitioner, involving a knowledge of medical jurisprudence,—I mean his position and duties as a medical witness. Professor Guy very appropriately remarks that "as witnesses in courts of law medical men have duties to perform for which the ordinary practice of the profession affords no adequate preparation, and, until of late years, medical education no proper training, and medical literature no sufficient guidance." As has been aptly

remarked by another, "a man may be well qualified to practise medicine as a physician or surgeon, and yet find himself very deficient when called upon to act as a medical witness." A notable illustration of this is afforded in the person of the illustrious John Hunter. This distinguished anatomist and surgeon was called as a professional witness for the prisoner, in a certain memorable trial for poisoning with laurel-water. In the course of the cross-examination, the great man completely broke down; he was unable to give a satisfactory answer to the final question put by the court, whether the death proceeded from the poison, or from some other cause. Hunter candidly admitted his deficiency, although he suffered most acutely from the mortification entailed thereby; and we are told that he deeply regretted to the day of his death, that he had not given more attention to subjects of this nature.

I think we are now prepared to understand that the duties of the medical jurist are quite distinct from those of the mere physician or surgeon. While the latter looks only to the treatment of disease or accident, and the saving of life, the object of the former, in a large proportion of cases, is to aid the law in discovering the perpetrator of a crime, or in rescuing an innocent person from an unjust charge. For instance, a medical man is summoned to attend a person laboring under the effects of a fatal poison, criminally administered, but at the time he may have no suspicion of the fact. In spite of treatment, death ensues. Here the function of the practitioner ceases, while that of the medical witness begins. It is utterly impossible for him now to escape giving evidence, or to shift the responsibility upon another. The law will insist upon his appearance, first at the coroner's inquest, and afterwards at the assizes. Now, I assume that, as a regular licensed practitioner, he is fully competent to answer every question put to him in the court-room relative to the general properties and effects of poisons, the quantity of each required to destroy life, the time when they prove fatal, the post-mortem results, etc. Then, if it is objected that the death was caused by disease, and not by poison, the searching inquiry will be as to what diseases resemble poisons in their symptoms, effects, and post-mortem characters; and, lastly, the liability to fallacy in the chemical

processes employed to detect the poison. This is only one of the many instances which illustrate the special duties of the medical jurist, and how they differ from those of the mere practitioner of medicine.

This leads me to recommend, as a matter of the greatest importance, the cultivation of the faculty of close and minute observation, on the part of those who wish to become proficient in this science. To observe well is one of the highest attainments in the medical art; but it is pre-eminently important to the medical jurist. Whenever he is summoned to a case, let him observe carefully and accurately *everything* around him, even the minutest circumstance. Nor let it be supposed that the cultivation of this habit of minute observation is at all incompatible with the highest professional character. No one ever doubted the skill and ability of Sir Astley Cooper as a surgeon, yet he cultivated this very habit to a remarkable degree; and, on a certain occasion, when he was summoned to visit a gentleman who was shot by a pistol-ball, this faculty was of signal service in enabling him to point out the murderer by a close observation of the direction of the ball, and the relative position of the injured man; and finally leading him to the conclusion that the weapon had been fired by a left-handed person.

I suppose there can hardly be a more embarrassing position for a medical man to occupy, than when for the first time he goes upon the witness-stand, to testify before a crowded court-room, in a capital case, and to deliver his *opinions* which may affect the awful issue of life or death to the prisoner at the bar. If summoned simply as an expert,—that is, to give his opinion on matters testified to by others,—his responsibility is, if anything, rather increased. But if he has first thoroughly studied the case, and scrupulously examined all sides of the question, and is master of the science of legal medicine, he need have no fear of the result, no matter how much he may feel annoyed and provoked by the attempts of a rude and blustering counsel, in the cross-examination, to intimidate him. Knowing that he has been sworn to tell the whole truth, and conscious of the desire *only* to bring out the truth, he will maintain a calm and dignified composure as a witness; he will not be betrayed into angry rejoinders to counsel, nor into an attempt to argue with him; he will

confine his answers strictly to the questions put to him, avoiding all prolixity, and all attempts to display his knowledge by haranguing the court and jury. He will not allow his temper to be ruffled (though if young in the business he will be sorely tempted), when questioned by a flippant counsel as to his professional abilities and opportunities, the number of cases he has attended, the mistakes he has made in his practice, and many other little matters calculated to vex and annoy him. Nothing makes a witness appear in a more ridiculous light, nor more prejudices his testimony before the court and jury, than the exhibition of a testy, irritable disposition when thus under fire. He should therefore most scrupulously guard against it.

I have already said that all his replies to counsel should be direct; they should never be evasive nor ambiguous, since this suggests a suspicion of either ignorance or dishonesty on his part. The answers should be given in a clear, audible tone of voice, and directed rather to the jury, inasmuch as they are specially interested in obtaining the information requisite to guide them in their verdict.

As a final suggestion, let me venture particularly to recommend the medical witness to avoid as far as practicable the use of all technical words or phrases. This is one of the most common and grievous faults to which he is exposed. From long habit of expressing himself before medical assemblies in technical and scientific language, he is led to employ, unconsciously, the same phraseology in the court-room, forgetful that neither the jury, court, nor counsel can possibly comprehend his learned utterances. How, think you, would an average jury understand his meaning, if, in describing a post-mortem operation on the head, he informed them that "he had reflected back the integuments and exposed the calvaria"? Would it not have been much plainer to them, and therefore much better for him, to have simply stated that "he turned back the scalp and exposed the skull"? How very few will know what he means when he talks about the "parietes of the abdomen," the "reflections of the peritoneum," the "os calcis" or "os femoris," the "dura mater," "pia mater," "corpus striatum," etc.? How far better to employ the simplest possible terms, and the plainest English, in describing what may be of the greatest importance for the

jury to comprehend! Many of you have doubtless read of the laughable scene described by the late Professor Taylor as occurring in one of the English courts at a trial for assault and battery, where the medical witness, in giving his evidence in the case, informed the court that "in examining the prosecutor he found him suffering from a severe contusion of the integuments under the left orbit, with great extravasation of blood, and ecchymosis in the surrounding cellular tissue, which was in a tumefied state. There was also considerable abrasion of the cuticle." This magniloquent description for a time bewildered the court, until it was resolved by the judge himself into the simple words—a *black eye*. Surely, no man of sense need be told that all such affectation and pedantry are in the worst possible taste, and are calculated to bring the witness into deserved contempt.

I have thus, gentlemen, ventured to offer you a few hints of a practical character, which, it occurred to me, might possibly be of use to those members of your Society who have not as yet had much experience in medico-legal matters. To many of you, doubtless, my suggestions may have appeared somewhat trite; but I shall feel gratified if I have succeeded in inspiring even a few of your members with a more lively interest in the pursuit of medico-legal knowledge, and a stronger determination to enlist the sympathy and co-operation in our city of the two great professions of medicine and law.

ORIGINAL COMMUNICATIONS.

THE EXAMINATION OF URINE.

Remarks read before the West Philadelphia Medical Society, September 3, 1883,

BY CHARLES W. DULLES, M.D.,

Surgical Registrar to the Hospital of the University of Pennsylvania, Fellow of the College of Physicians of Philadelphia.

THE work of analyzing the urine, as described in the books and as practised when a complete investigation is desired, is elaborate, and calls for special apparatus, as well as for special skill in handling it. But that which is of most common utility demands nothing which every practitioner may not possess. The only apparatus needed is a urinometer, some litmus- and turmeric-paper, some acetic acid, a few test-tubes, means of applying

heat, a solution of caustic potash, a microscope, with slides and cover-glasses, and eyes to use them.

With these one may learn all that is ordinarily necessary about the specific gravity and reaction of the urine, the proportion of urates and phosphates, and the presence or absence of albumen and sugar, and of tube-casts or other deposits. Other points of investigation which are treated of in the books are of insignificant importance compared with these, and a knowledge of them is rarely demanded. What I mean to speak about this evening is nothing of this sort, but the best way to make a satisfactory examination of the urine for ordinary clinical purposes.

Specimen.—The first thing to be done, if one wishes to analyze the urine, is to get a proper specimen; and of all the steps towards one's goal none is of greater consequence than this. It will not do to say to a patient, "Send me a sample of your water." One must be more precise, or he may find, as I have done, carbonate of magnesia, or shreds of muscular tissue, or the yeast-fungus of beer, coming apparently from a healthy bladder. The sample must be unadulterated. To secure this, my plan is to order a clean bottle and clean cork to be gotten from the druggist, directly into the former of which the patient is to urinate, if a man. For women, I order, in addition, a chamber-pot to be washed clean with hot water and scoured dry with a clean cloth. Into this the patient, and no one else, is to pass her water, and then pour it into the clean bottle.

The time of getting the specimen is of some moment, too. The most typical sample will be made up half of the last urine before bedtime and half of that first passed in the morning.

Such a specimen should be labelled with something to indicate from whom it comes and when it was collected, and sent at once to the examiner. To let urine stand any length of time is to risk the reliability of the whole examination; for it may undergo the acid or the alkaline fermentation, and give results absolutely contradictory to those which it should.

Inquiry should always be made as to the amount of urine passed in twenty-four hours, as well as the frequency of urination by day and by night, and the amount passed at each time. Inquiry about the latter serves as an invaluable check upon errors in regard to the

former, which are extremely common. Besides this, the answers often afford most useful hints as to the true significance of other facts ascertained in the ordinary examination.

One should never neglect to learn whether there is any local condition of the penis or urethra in men, such as balanitis, gonorrhœa, etc., or of the urethra, vagina, or uterus in women, such as caruncle, vaginitis, leucorrhœa, etc., which might supply a misleading element to otherwise normal or abnormal urine.

Thus provided with a proper specimen and forewarned if there be complicating elements present, the examination proper may be begun.

Method of Examination.—It is advisable, I think, to keep a little blank-book in the place where one usually examines urine, and to enter in it the details of each examination, not only for reference, but also in order to profit by accumulated experience.

Order of Examination.—Further, a certain order should always be observed, and not a desultory no-method. This order will naturally put first those points of investigation which require no apparatus, taking up afterwards those which require simple apparatus, and, finally, those where the apparatus is more complicated and where more time is demanded.

Thus, it is best to investigate and note—first:

A. THE PHYSICAL CHARACTERISTICS.

1. The amount passed daily.
2. The color,—its agreement with or deviation from the normal.
3. The clearness or turbidity, and whether the latter is uniform or flocculent.
4. The amount and character of the sediment when first seen.
5. The odor,—whether it is normal, faint, strong, fragrant, or offensive.
6. The reaction, and its degree, approximately.
7. The specific gravity.

The last point requires the decanting of a sufficient quantity of the urine into a wide tube, and the use of the urinometer.

The lower part of the specimen should now be poured into a subsiding-glass, to await microscopical examination of its sediment.

The subsiding-glass ought not, in my opinion, to be conical, but one with perpendicular sides. I prefer and always use

a tall test-tube with a foot. This should be covered (I use a pill-box lid or a flat card), to keep out dust and other foreign matters, and set aside to be examined after twenty-four or forty-eight hours.

First Examination of Sediment.—My own practice is next to take the bottle from which the urine was poured, and, by shaking it round and striking the bottom on my hand, to get one more drop from it for immediate examination under the microscope. This sometimes reveals as much as the later examination, and often furnishes a check as to the formation or change of crystalline deposits.

In any case, one may now proceed to determine what is of most consequence in regard to—

B. THE CHEMICAL CHARACTERISTICS.

Of these I will consider here only four :

1. Urates.
2. Phosphates.
3. Albumen.
4. Sugar.

Urates.—Ordinarily an excess of urates is indicated by a high color, and a turbidity which is dispelled by heating. This may be confused, however, by the presence of albumen, which begins to be precipitated as the urates are dissolved by the application of heat. In such a case the urine may be tested by standing the vessel containing it in a cup of hot water, by which heat enough to dissolve the urates will be secured, but not enough to throw down the albumen. Another indication of excess of some member of the urea group is found in a high specific gravity, with absence of a large amount of sugar. Another is unmistakably gathered if the addition of acetic acid to a clear urine causes at once a fine whitish precipitate to be thrown down. A diminution of the proportion of urates is indicated by a very light color and a low specific gravity.

Phosphates.—The presence of an abnormal amount of phosphates in the urine is usually indicated by a pale color, and sometimes by turbidity. Any turbidity which is cleared up by adding enough acetic acid to give the urine a distinct acidity may be set down to the presence of phosphates. On the other hand, rendering the urine distinctly alkaline and warming it will cause a precipitation of phosphates. If this precipitate is light and finely flocculent, it is probably normal.

It cannot be regarded as abnormal unless it falls densely or to a greater depth than a third of an inch in a test-tube three-quarters of an inch wide with two inches of urine in it. An abnormal diminution of the phosphates is indicated by a total absence of deposit, or by its being very small indeed.

Albumen.—The presence or absence of albumen may be determined by a variety of tests. Two of these are so superior in reliability to all others that I will mention them alone.

Nitric Acid Test.—The first is the "nitric acid" test. This is carried out by what is called "underlaying" the urine with strong nitric acid. This is usually done by pouring nitric acid down the inclined side of a test-tube containing urine, or urine down a tube containing nitric acid. A better way than either I have found to be the following: Pour urine to a depth of half an inch into a small test-tube; then take up about one-quarter fluidrachm of nitric acid in a long glass tube drawn to a tolerably fine point; close the top with a finger; pass the point down to the very bottom of the tube, and let the nitric acid descend slowly by rotating the glass tube under the finger and very gradually admitting the air. If the point of the tube be fine, the finger may be removed at once, and the descending column of acid, as in the preceding case, will lift the urine gently up, and an unbroken line of junction will be the result. This method of underlaying is the most delicate and most exact that I know of. If albumen be present, there will form at the line of junction between the acid and the urine a white, or whitish, layer of coagulation, the density and thickness of which indicate the proportion of albumen in the specimen. This test is liable to some confusion if the urine be turbid or much discolored, and also when there is present a large proportion of urates or carbonates. The former are sometimes precipitated as the urine becomes more acid, and form a cloud near the line of junction, which might deceive the unwary. But error may be avoided by observing that they form a *cloud*, and not a *layer*, and that they accumulate *above*, not at, the line of junction. The presence of an excess of carbonates will cause an effervescence, which may be violent enough to drive out all the contents of the test-tube.

Boiling Test.—The best test for albumen—all things being considered—is the “boiling” test. This may be applied by pouring a test-tube half full of urine, adding two or three drops of acetic acid, and boiling the mixture. If it becomes cloudy or opaque, albumen is present; if not, it is absent. The density of the coagulation, from a faint opaline clouding to absolute solidification, indicates the proportion from 1:1000 to 1:20. The latter proportion is about that of blood-serum: so it is easy to see how greatly exaggerated are statements that urine contained fifty or ninety per cent. of albumen.

Sugar.—Every sample of urine should be examined for sugar. Fortunately, saccharine diabetes is rare, but the possibility of its occurrence ought not to be overlooked. To find out whether it is present is among the easiest processes of chemical analysis. It requires no standard solution, no salt of copper, no bismuth, no yeast, only a solution of caustic potash, one part to eight parts of water, a test-tube, and heat.

Of the suspected urine a few inches in depth should be put into a test-tube, and half the quantity of the potash solution added and mixed. Heat is then to be applied, and, when the boiling-point is reached, if sugar be present the mixture will assume a darker hue, varying from light canary, which indicates the presence of one per cent., to black, which shows the presence of ten per cent. of sugar. While I am convinced that this test is as trustworthy as any I know of, and more trustworthy than many, yet its application, like that of other tests, has led me to think little of the indication of very small proportions of sugar, such as might be inferred from the canary color. For, either all the tests, except the fermentation test, react to other substances than sugar in the urine, or else sugar is present in small quantities in almost all urines. At any rate, a light canary-colored reaction with caustic potash is of very common occurrence.

With the investigation of these four constituents or ingredients of urine, all the chemical analysis that is of importance to the clinician will be finished. The tests for other substances, described in the books, have interest for the student of physiological chemistry, and occasionally furnish brilliant points for a lecture or paper. But the means of detecting and estimating carbonates, sulphates, indican, bile-pig-

ment, biliary acids, and even urea, will have to be made much more simple and much more exact before they can furnish much better information than any intelligent practitioner can gather without their help.

There remains, after the steps described, nothing to be done but to wait twenty-four hours for the sediment to fall, and then to determine the—

C. MICROSCOPICAL CHARACTERISTICS.

This procedure is to many practitioners impossible, because they have not the necessary apparatus. To others it may be of little value, or even delusive, because they have not the experience necessary to make it trustworthy in their hands. But it is in many respects the most important part of the whole examination. Indeed, it is an indispensable part.

Unfortunately, almost nothing can be said about it which can take the place of actual demonstration and long practice, although much can be learned by studying well-made plates of urinary sediment: the best of which, that I know of, being contained in the excellent Atlas of Ultzmann and Hofmann, published in Vienna, in 1871.

But a few hints drawn from my own experience may not be out of place here.

In cases where there is a dense deposit of urates entangled in mucus, it is well to let the urine stand for a few minutes in hot water, or to let it settle in a very warm place. Keeping the urine acid will prevent confusion on account of dense precipitates of phosphates; when they form, a few drops of acetic acid will clear them up without destroying other deposits. In every case where there is a dense deposit it is important to examine a drop drawn up with a pointed glass tube from several levels,—the lowest, the top, and the middle. After this, it is well to pour off all the supernatant urine, to shake the residuum up, and to examine a drop of this. When there is a well-marked nubecula, I think it important to examine a drop from just above it, as well as several from the bottom of the tube.

Some errors may be avoided by bearing in mind that fibrilli of mucus may look like hyaline casts, and that they may be distinguished from these by their very great length. To detect this often requires very careful focussing, by which they can

be followed across the field of the microscope and recognized by their general appearance, as well as by the length alluded to. When such fibrils are encrusted with urates, one must be especially on the lookout not to mistake them for casts. It is well to be on one's guard also against the appearance of flat epithelium seen on edge. This sometimes looks astonishingly like hyaline casts, but may be recognized upon slightly moving the cover-glass, or by excluding the idea of hyaline casts from their solitary appearance among easily-recognized epithelial scales.

Another practical point, upon which I would lay stress, is to examine the urine on the slide round the edge of the cover-glass, and not that only which is under it. Not infrequently an investigation which revealed nothing so long as only the latter was searched will prove very instructive as soon as the former is studied. For suggestive deposits are sometimes washed away from under the cover when it is allowed to fall upon the slide.

In concluding this part of our study, I will give a schedule for examining a specimen of urine, which includes the steps already given in detail.

SCHEDULE FOR AN EXAMINATION OF URINE.

A. PHYSICAL EXAMINATION.

Note 1. Amount passed in twenty-four hours.

2. Color.

3. Transparency or turbidity.

4. First sediment,—amount and character.

5. Odor.

6. Reaction.

Pour off upper part into a tall, broad test-tube or urinometer tube, and shake up lower part and pour into a tall subsiding-glass, cover it, and reserve for microscopical investigation after twenty-four hours.

Note 7. Specific gravity.

B. CHEMICAL EXAMINATION.

Pour about two fluidrachms into a test-tube, and

1. Add a few drops of acetic acid. (If the urine be alkaline, enough must be added to make it distinctly acid.)

If sample was clear and remains so: no inference.

If sample was clear and becomes cloudy: excess of urates.

If sample was cloudy and remains so: excess of urates.

If sample was cloudy and becomes clear: excess of phosphates.

2. Heat slowly until it boils.

If sample was clear and remains so: no albumen.

If sample was clear and becomes cloudy: albumen is proved.

If sample was cloudy and remains so: probably due to bacteria.

If sample was cloudy and becomes clear: excess of urates proved.

3. Add to sample, while warm, half its bulk of solution of potash.

If sample was clear and remains so: phosphates are diminished.

If sample was clear and becomes flocculent: due to phosphates.

If sample was cloudy and remains so: bacteria or foreign matters.

If sample was cloudy and becomes clear: due to redissolving of albumen.

4. Heat again at top.

If a canary or rum or brown or black color appear, it shows sugar.

C. MICROSCOPICAL EXAMINATION.

Examining a drop of the sediment left after decanting the urine from its bottle will often show all that a later examination reveals, and it ought to be tried. But in every case, after allowing a portion to stand for twenty-four hours, several drops in succession, from different levels of the sediment, should be carefully examined, and a note made of the result. A note should always be made of the reaction of the urine at the time when a microscopical examination is made.

We now come to another part of our subject,—namely, some points to be borne in mind in drawing clinical conclusions from an examination of the urine.

I think experience will warrant a modification of certain views not uncommonly held in regard to what is to be regarded as normal or abnormal in urine. The amount passed daily, for example, is usually set down in the books as about three pints, with a caution, it is true, that this is subject to variations. But this does not convey any adequate idea of the amount of variation which may exist without harm to the health. Now, this variation may range from one pint to many. The former is rare, and to be regarded with composure perhaps only in persons whose vegetative functions are very inactive,—as the old and

spare, for example,—or when the skin or bowels are very active; but its possibility is not to be overlooked in the zeal to detect morbid phenomena.

The latter—a large excretion of urine—is very common, and I am convinced that the amount normally excreted by healthy men is nearer five pints than three. In any case, one thing is quite clear to me,—viz., that the fixing of a given quantity as the average amount of urine to be excreted in health is utterly delusive, and that no more can be assuredly said about this than that the persistent excretion of very small or very large quantities should excite suspicion and investigation to learn whether the cause be consistent with health or not. Another point is that the *specific gravity* of healthy urine cannot be set down as being 1.020, if thereby there be the faintest implication that a departure from this—even a wide departure—is to be regarded as abnormal. That the contrary is the case I have satisfied myself by a large number of tests made in the past eight years, so that I know that a range from 1.004 to 1.040 is within healthy limits. The low figures accompany free discharge of urine, with the use of succulent food and large quantities of fluids. The high figures are found in summer-time when the perspiration is great, or at any time when the food is dry and the action of the skin or bowels is vigorous.

The point I would make in regard to this, without disparaging the value of an arbitrary standard for comparison, is that the varying specific gravities of urine have little diagnostic value, except when made significant by some other features. Thus, there can be no question of the indications of rising or falling figures when it is known that sugar is present in abnormal quantity or when a Bright's disease is present. But I know no other morbid states in which the figures of the urinometer disclose anything of importance which cannot be learned otherwise.

Another physical characteristic of urine is the *reaction* of urine. This is said to be faintly acid, with occasional faint alkalinity due to ingesta. In my own experience, I have found faint alkalinity very common. It has usually been observed in persons of low physical tone, but I do not regard it as of much consequence unless accompanying some more tangible evidence of renal or bladder disorder. Strong

alkalinity of freshly-passed urine is quite another thing, of course.

Strong acidity of the urine is not uncommon, and it sometimes indicates danger. It should always lead to a microscopical examination, to discover whether crystals of uric acid, the commonest origin of stone in the kidneys or bladder, are to be found.

The *color* of the urine is subject to somewhat the same influences as the specific gravity, rising and falling with this. But, in general, as is well known, a high color is indicative of rapid tissue-metamorphosis, and a low color of the reverse. The former is found in acute systemic disorders, the latter in chronic troubles. Pale urines generally grow paler, and high-colored urines more high-colored, after standing.

Of the *odor* the same may be said. Peculiar odors are often due to ingesta, as, for example, asparagus or turpentine. A fetid odor when the urine has just been passed is usually indicative of cystitis.

The significance of *urinary sediments* is to be clearly understood only after a microscopical examination. But all are familiar with the common brick-dust deposit of concentrated urines. The nubecula, which consists of mucus, and which forms in healthy urine after it stands a few hours, often misleads patients, but, of course, would not mislead a physician. But there is a peculiar sediment found in cases of cystitis, especially where this is set up by a stone in the bladder, which is almost pathognomonic. This is a slimy mass, which, on pouring, leaves the vessel very much as the white of an egg leaves its shell, sliding off in a soft but coherent mass.

The proportion of *urates* contained in any sample must be estimated in connection with all the other circumstances of the case. From my own experience, I should say that this is usually only confirmatory of a diagnosis made without its help. Thus, in acute fevers, in disorders of the liver, in heart-disease, one has probably already learned what is straining the excretory powers of the kidneys before the excess of urates is discovered.

As to an excess of *phosphates*, I believe its discovery never discloses any new feature of a case. When it is found, one has ordinarily abundant other evidence of the weak constitution or nervous strain of his patient, and ordinarily the physician examines for phosphates, in order to gratify the natural desire to see with his eyes what

is usually looked upon as the excretion of wasted brain- and nerve-tissue. A diminution of phosphates is compatible with perfect health, and has no important significance, taken by itself.

The presence of *albumen* in urine is quite another matter. Except in very minute proportions and at intervals, albumen indicates organic change in some part of the urinary apparatus. Any condition which adds pus or blood to the urine will be accompanied by the presence of albumen. Such a condition may exist in the urethra, the bladder, the ureter, the pelvis of the kidney or its tubules or parenchyma. Which of these is involved, the microscope and a rigid general examination of the patient alone can determine. The same is true of albuminuria due to nephritis. Here the microscope alone can determine what is the nature of the change, and whether it is acute or chronic. The chemical discovery of albumen should in every instance be followed by a careful microscopical examination. To neglect this is to commit an error which might lead to irreparable harm.

The detection of very small quantities of sugar in the urine is, as has been stated, a common experience, and may be taken too seriously. If it does not increase, and if the specific gravity of the urine be moderate, it may be regarded as of no unfavorable clinical significance. But when the specific gravity is high and the other evidences of glycosuria are present, of course it is important, and cannot be watched too carefully.

Finally, as to *urinary sediments*. These are the real and infallible proofs of what is going on in the genito-urinary organs. Each means a definite thing, and its presence or absence gives assurance as to the state or condition of the urinary apparatus in a way that nothing else can do. I have not time to go into details, in addition to those already given under the heading "*Microscopical Characteristics*,"—this is the province of the text-books,—but I cannot leave the subject without emphasizing again their great importance.

Thus, gentlemen, I have tried to indicate, in the first place, the simplicity of the process of examining urine in a way perfectly satisfactory for clinical purposes, and to show how little it demands complicated apparatus, how entirely it is within the command of every medical man.

In the second place, I have tried to point out a few points, deduced from experience, which I think may profitably be borne in mind in estimating the significance to be attached to what may be discovered in the course of a physical, chemical, and microscopical examination.

In conclusion, I will give a list of the apparatus required for such an examination as has been described :

Some test-paper.
A urinometer.
A test-tube.
A sediment-glass.
Acetic acid.
Solution of caustic potash. (One part to eight of water.)
A spirit-lamp.
A pointed glass tube.
A microscope, slides, and cover-glasses.
It will be found convenient to keep a blank-book for records in one's laboratory, and to have tacked up against the wall a card on which is written the following, to help to secure order and system in one's examinations:

1. Amount.
2. Color.
3. Clearness.
4. Sediment.
5. Odor.
6. Reaction.
7. Specific gravity.
8. Urates.
9. Phosphates.
10. Albumen.
11. Sugar.
12. Deposits.

I take the liberty of recommending such simple matters to others, only because I have found them helpful to myself.

REPORT ON THE PROGRESS OF DERMATOLOGY.

BY ARTHUR VAN HARLINGEN, M.D.,
Professor of Dermatology in the Philadelphia Polyclinic.

EPITHELIOMA.

M. M. BLUM and Duval (*Arch. Gén. de Méd.*, Août, 1883), after carefully studying the various statements made by authors as to the nature of epithelioma (*cancroïde de la peau*), give their opinion that the study of this affection must be undertaken anew and from the foundation. Heretofore, epithelioma of the skin has been considered as a morbid entity subdivided into several varieties according to

the predominance of one or another constituent element. It is necessary now to study the modifications which may be impressed upon it by its situation, or by the nature of the elements in which it is developed. Certain forms of epithelioma are exclusively seated in the upper part of the face. Certain others, presenting characteristic features, are found on the back of the hand. The latter are rare. Gurlt encountered only eight cases in one thousand three hundred and seventy-seven cases of epithelioma.

Epithelioma of the hand is rarely met with except between the ages of sixty and eighty. It usually occurs in the site of an old scar, though it may develop rapidly in a recent cicatrix. A case illustrative of this is given by the authors, accompanied by a wood-cut.

Aside from their etiology, epitheliomata of the hand may show marked peculiarities in development. A case, with illustrative wood-cut and several pictures of microscopic sections of the growth, given by the authors, illustrates this. Here cicatrization of a spontaneous character took place in the centre of the tumor. Their conclusions show that the origin of the epithelial tumor in the case examined was only in the inter-papillary portions of the rete Malpighii. The hair follicles, sebaceous and sweat glands did not take any part in the new formation. Some of them, however, were deformed by the outside pressure of the growth.

The retrogression of the elements of the tumor was due to an inflammatory process of the derm, or to a formation of cicatricial connective tissue which surrounded and strangled the lobules of the tumor and caused resorption.

The authors conclude—1. That epitheliomata present multiple clinical varieties, the gravity of which depends on their seat and mode of evolution rather than upon their histological structure. 2. They are susceptible (under rare and exceptional conditions, it is true) of spontaneous cure over a greater or less area. The attentive study of such cases may perhaps serve as a guide to the rational treatment of these tumors.

THE NATURE AND TREATMENT OF LUPUS.

In a very important article published in the *Annales de Derm. et de Syph.*, August, 1883, Besnier, the distinguished head of

modern French dermatology, gives a full review of our present knowledge of the pathology and treatment of lupus.

In his opinion, lupus is in the strictest sense a scrofuloderm. All patients who have lupus are scrofulous or scrofulotuberculous. The arguments which have been brought forward to controvert this theory are as follows: 1. Lupus is not hereditary. 2. The symptomatology of lupus differs from that of tuberculosis (properly so called) of the skin or mucous membrane. 3. Lupus does not lead to tuberculosis. 4. Experiments upon animals show that lupus is not inoculable locally or by infection.

Besnier examines each one of these propositions in order to disprove them. As to the first, he says that the fact that lupus is not hereditary is the best proof of the local character of tuberculosis in its beginning. He has often seen patients with lupus become tuberculous, but he has never seen a confirmed tuberculous patient develop lupus.

As to the symptomatology of lupus differing from that of tuberculosis, if this were not the case why should they have received separate names? Are there not varieties of pulmonary consumption, each with its symptoms peculiar to itself? Are there not, indeed, varieties of lupus, from the benign patch on the surface of the cheek to the rapidly-eroding serpiginous varieties?

To say that lupus does not lead to phthisis is to repeat a legend which has been handed down from generation to generation, but which has no basis in fact. So far from it, modern dermatological authorities unite in admitting pulmonary phthisis as a complication of lupus to be feared. The time to state the exact proportion of lupus patients who suffer from phthisis has not come; but, turning to his own wards, Besnier finds that of thirty-eight cases of lupus, seen in June and July of the current year, no fewer than eight, or twenty-one per cent., showed physical signs of pulmonary consumption.

Finally, experiments lately made in animals go to show that inoculation with lupus-matter in animals may give rise to tuberculosis.

Lupus, therefore, in Besnier's view, being a local tuberculosis, and liable to lead to a general infection of the skin, its prompt and thorough treatment becomes a matter of paramount importance.

With regard to general treatment, the

health of lupus patients may and should be improved by tonics, etc., but these cannot be relied upon to affect the lupus itself in any direct way. Cod-liver oil has been recommended by some authorities, but long-continued experience shows that it has no influence on the disease. It is the same with regard to iodine, iodide of starch, iodoform, and iodide of potassium. Sulphur and arsenic may affect the general health favorably, especially when used in the natural mineral waters, but neither these nor any other internal agents can have a specific effect on the lupus.

The simple local medication of lupus may be of three kinds,—antiphlogistic or emollient, discutient, substitutive. The first, including vapor-baths, starch poultices, etc., have, of course, no action on the course of the disease, though they may be useful adjuvants. The discutients, as mercurial plaster, tincture of iodine, etc., may have in some few cases a temporary and apparent beneficial effect, but are rarely useful even in a temporary way. The substitutive irritants act just as an attack of erysipelas may act in exciting a frank inflammation, which seems to carry off with it a certain amount of morbid growth. Besnier has, indeed, never seen a case of lupus benefited by an attack of erysipelas. Repeated vesication represents the class of agents here discussed, and this, the best of all, has but little effect on lupus. The preparations of iodine and mercury, so long employed, should be entirely set aside. Used inefficiently, they give rise to much pain and annoyance; used thoroughly, they cause deep, irregular, unmanageable cicatrices, in the midst of which the lupus-growth makes its appearance again.

The surgical methods employed in the treatment of lupus are of three kinds,—extirpation, scraping, scarification. Of these, the latter is certainly the most simple and complete when it can be employed with propriety. The extent of the disease, and, still more, its seat so often on the face, nose, lips, etc., will, however, frequently forbid such operations, and even when they can conveniently be performed a cicatrix is left behind, often vicious, and in which occasionally the disease makes its appearance again. A somewhat similar objection is given by Besnier against the use of the curette for scraping. If the scraping is done thoroughly it is almost as bad as cutting the lupus out, while, unless it is done

thoroughly, relapses are pretty sure to take place. Acupuncture, multiple scarifications with needles or small knives, or “dilaceration,” as Besnier terms the operation, is in his opinion the best of these surgical operations. The incisions are made in close proximity and to a depth corresponding to that of the growth to be operated upon. They should in some cases be crossed by a series of others, so as to make lines like shading in a pen-and-ink sketch. The chief objection to this procedure is that it must be repeated so frequently in order to remove the growth thoroughly. Small patches are seen to be left, and these must be gone over again and again.

The addition of caustics, as in the injection of solution of chloride of zinc, etc., by means of a hypodermic syringe, whereby a drop of solution is placed under the skin at one point and another, is a painful and not a particularly useful method. In one case where solution of perchloride of iron was used a cure resulted, but the skin was tattooed with indelible iron-stains.

The chemical caustics *en masse*, as caustic potash and arsenic, Besnier condemns without reserve. Arsenic is highly dangerous.

Theoretically the actual cautery is the best method of treatment, and indeed this is recommended by many authorities, but Besnier rejects it because of the extensive and useless destruction of tissue, because it necessitates the use of general anæsthesia, and because the process of cicatrization must be followed up and directed by means of repeated cauterizations with nitrate of silver.

The form of treatment preferred by Besnier, and indeed now used by him to the exclusion of all others, is what he calls “interstitial,” punctate or linear cauterization with the thermo-cautery or galvano-cautery. The advantages possessed by this method are that the amount of destruction of tissue can easily be regulated, that healing takes place rapidly, and that there is no danger of spreading the disease by the operation itself, which Besnier thinks possible in any cutting operation for the relief of lupus.

The thermo-cautery, which is now within reach of all practitioners, can fill all ordinary indications in the treatment of lupus, but the galvano-cautery is more generally useful, because the knives and points can be made of all desirable sizes and shapes

to fill every indication. Besnier figures no less than nineteen different shapes which he makes use of from time to time. The battery he employs is a bichromate battery, the intensity of action being regulated by an assistant. The platinum points are only heated to a red heat. The difference of sensation where healthy tissues are reached enables the extent of action to be carefully regulated. The after-treatment is perfectly simple: a little powdered starch or a water dressing is all that is required.

A NEW LOCAL APPLICATION IN PSORIASIS.

Auspitz (*Wiener Med. Wochens.*, Nos. 30 and 31, 1883), considering the various methods of external application in psoriasis as inefficient in some particulars, has devised a mixture of chrysarobin and "traumaticin," the liquor gutta-perchæ of our Pharmacopœia. The advantage of this preparation is that the chrysarobin cannot be rubbed off on the clothes or spread about on the healthy skin, but remains in the place where it has been painted for several days.

The method of using it is as follows. The scales are to be removed as completely as possible by means of a hot bath with soap, after which the solution of chrysarobin (ten per cent.) in liquor gutta-perchæ is to be rubbed into the patches with a brush, the bristles of which have been cut short so as to allow a certain amount of friction to be employed. The pencilling and rubbing with the solution is to be repeated daily, the crusts being removed by soap and water every two or three days if they accumulate. Five to ten days usually suffice to remove the patches completely.

FEIGNED SKIN DISEASES

Two interesting cases have recently been reported. Dr. I. B. Fortner (*Lancet*, August 25) gives the case of an unmarried woman 25 years of age, who applied for the relief of a supposed loss of power in the thumb, probably hysterical. Shortly after coming under observation, certain peculiar lesions showed themselves on the back of the right hand and wrist, consisting of four oval abrasions, three-quarters of an inch in length by one-quarter broad, and presenting the appearance of a blister from which the cuticle had been removed, leaving a raw surface bathed in serum. Zinc oxide ointment was applied and the limb securely strapped and bandaged, when the sores quickly healed. New ones ap-

pearing a little later, Dr. Fortner, suspecting the artificial character of the lesions, took occasion to rub a stick of lunar caustic over each abrasion until considerable pain resulted. This acted as a deterrent, and no more sores appeared. Seven months later, however, the patient returned with the same lesions. She belonged to a markedly neurotic family, and Dr. Fortner very properly reached the conclusion that the lesions had been artificially produced, probably to create sympathy.

A second case was reported by Dr. Murrell (*Lancet*, vol. ii., 1883, p. 447). A young girl of 14, subject to fits, showed certain lesions which had appeared on and off for a year previously, breaking out immediately after the nervous phenomena called "fits." According to the history given, the arms and legs alone had been affected, the eruption coming on in the night, and the lesions presenting, when examined, the appearance of blisters or burns, and taking a long time to heal. Of late "bladdery heads" had formed full of water, and these burst leaving sores. On examination, several elongated patches like recently-healed blisters, one and a half inches long by one-half inch broad, could be seen on the arms and legs and under the mammary region. Although when taxed by the examining physician the patient persistently denied having produced the lesions upon herself, yet there seemed no doubt that the lesions were artificial and self-made.

NOTES OF HOSPITAL PRACTICE.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

SERVICE OF PROF. H. C. WOOD.

Reported by LOUIS J. LAUTENBACH, M.D.

A CASE OF EPILEPTIFORM NIGHTMARE.

THE first case which we have to-day is a very extraordinary one. The gentleman who is the subject of our study was formerly in the United States Signal Corps. While on duty he began to have some dyspeptic symptoms, with a sense of terror at night, and disturbed sleep. He first began to have spells two years ago, which have continued ever since. They have never occurred when he was awake, but have been nocturnal from the beginning. The spell begins with a scream,

which is described by those who have heard it as something unearthly in tone and violence. Indeed, since he has been here in the ward he has waked up patients who are even in the farthest part of the building. The scream is repeated two or three times, and then he begins to work his limbs with the utmost violence. The movements appear to be, to some extent, purposive. (If the character of the movements are such that the individual the subject of the attack gets up and throws his arms around an attendant, so that the involuntary acts are directed apparently with a definite purpose, we say that the movements are purposive.) We do not find the tongue bitten, nor does he wet the bed. He tries to spring out of bed. He strikes around violently, and has thus seriously injured himself as well as his attendants.

This morning he had an attack while asleep in a chair. He sprang forward, and would have plunged into the fire had not an attendant caught him. Every night he has at least one of these attacks, sometimes two or three. After the attack he is left in a condition of exhaustion, and the next day he is nervous and unable to work. It is a very serious case. He has been under Dr. Hammond's care, as well as that of other neurologists, without any benefit.

The first thing to make out in this case is the diagnosis; and the first question which presents itself is as to whether he is suffering from epilepsy or not, and this question must be studied very carefully before we can hope to come to any conclusion. The fact that the attacks came on after the age at which epilepsy usually develops is a grain of evidence against its being epilepsy. Then the movements appear to be purposive, and are not simple convulsions, and then, again, he does not bite the tongue, and there is no tendency to deep sleep after the attack; so that in all these respects the attack does not agree with pure epilepsy; yet you probably know that sometimes you have epileptic paroxysms in which active purposive movements occur. The case of a master-builder, related by Trousseau, who, when he was seized with an epileptic attack while at his work on a high building, would pass safely over the most dangerous places, affords a remarkable example of this.

Leaving now epilepsy, we will endeavor to find what it would be if it were not

epilepsy. We are now brought face to face with nightmare and somnambulism. In these conditions the eyes are sometimes open and sometimes shut, but are usually open. The patients rise, go down-stairs, and do various actions which are utterly outside of consciousness and about which the next day they have no recollection at all. They walk and act while consciousness is suspended. There is a definite relation existing between dreams and this nightmare. A horrible dream may so act on the lower centres of the brain that it may eventuate in action, or it may simply exhaust itself as a dream. Terror in these conditions always plays an important part. As the result of stimulation of the lower motor centres we may have either noises or the ordinary nightmare.

I remember that, when I was a medical student, near me there was a man in danger of secondary hemorrhage as a result of an operation. As there was no doctor near, they had orders to send for me if anything should occur. During the night I had the idea that a man was under the window calling me, saying that the patient was bleeding to death, while I, who should have been of so much help, was unable to get out of bed because I was paralyzed.

In these conditions a moment seems like an eternity. A man may think he is passing through weeks of horrible suffering, when he has been asleep but a few seconds.

As nightmare usually occurs, it is not of much moment. In the severer forms in children we have what are termed night terrors. The child wakes with a cry and is seized with various phantasies, which usually take the form of some horrible creature about to carry the child away, or of some monster injuring the child's friends. While this is occurring, if it be spoken to, although it may gaze at the speaker no comprehension of the meaning of what was said enters the child, but it will continue its vacant stare. If, however, the child be thoroughly roused, it will probably cry for a short time, so natural has the delusion appeared. The condition is one of horrible semi-consciousness, and it is usually from fifteen minutes to half an hour till the child can be appeased. Usually, when the subject of a nightmare is awakened, his mind is perfectly clear, except that he cannot believe that what he saw had not actually occurred.

A dream with automatic action is called

somnambulism ; with terror, with or without automatic action, nightmare. In nightmare there is always some horrible impending evil with which the subject is unable to combat. He feels as if he were destitute of the use of his muscles. Whether this case be one of epilepsy or not, it is always of more or less serious import and is by no means to be viewed as trifling. There have been cases where the ordinary nightmare has been the cause of destruction of a man's life. There is a medical teacher under my charge now who has such fearful dreams that he dreads to go to bed. If a man has the nightmare, the nightmare dominates the man's life. Everything is centred to avoid the terror and suffering it brings with it. Wealthy men who are the subjects of nightmare usually have an attendant who watches over them at night, and the moment the nightmare comes on wakes the patient ; and yet the patient will protest that he has been under the influence of the terrors for quite a length of time,—in fact, will frequently not believe the attendant that he was awakened the moment the nightmare appeared.

Whether this case be one of epilepsy or some one of these forms of nocturnal disturbance which are somewhat related to it, but which in some particulars are sharply defined from it, remains for us to determine.

I hardly think that we can call it nocturnal epilepsy, but that it must be placed near the ordinary nightmare of children. Against epilepsy we have the age ; there is no incontinence of urine at night ; there is no biting of the tongue ; there are no epileptic attacks unless asleep ; the movements are to a certain extent purposive. The scream of epilepsy is rarely repeated ; one unearthly, demoniacal scream circles about, filling all space, and then ends in silence. This man's scream is only hushed for a moment to break forth anew. This condition is an attendant rather of nightmare than epilepsy. The other day he said that he had no remembrance of dreams, but he now says that he has a troubled, confused sense of ugly dreams. He has never had any of the attacks except during sleep. The other day, the moment the scream was over the attendant spoke sharply to the man, and he immediately roused up.

I think the case one of nightmare due to a peculiar condition of the brain, of

whose pathology we may speculate, but of which we know absolutely nothing. This view of the case has been confirmed to a certain extent by the result of treatment. He has taken large doses of the bromide, and has become steadily worse under its influence. He has also been treated with large doses of arsenic, which seemed to do no good. Nothing has ever done him any good, although he has been under skilful treatment. We tried here in the hospital chloral in twenty-five-grain doses, but it had no effect on the prevalence of the attacks.

When we come to the treatment of nightmare in the child we must attend to the hygiene, get the health to the highest possible point, and then see that the child eats a light supper. Unless the supper partaken of be light, the rest is broken and disturbed, and dreams are produced by the heavily-loaded stomach.

We have also noticed that frequently a sudden shock, such as a cold douche given while the patient was under the influence of the nightmare, has broken up the habit. Cases of obstinate somnambulism are almost as trying as this man's case. Many cases of fractures have occurred from these patients falling from a height ; almost invariably this has cured the habit. Sometimes the habit of the nervous system has been successfully broken up by placing a bathtub full of very cold water so that when he gets out of bed he falls into the cold water. In this man's case we will try the effect of this treatment.

For the benefit of the attendants and of the residents, we will leave him sleep in the daytime and keep him awake at night. For about six hours preceding his sleeping hours he will not be allowed any food. The moment the attack comes on he will be soused with ice-water, in the hope that it will stop the attack and that possibly it may break up the habit permanently.

Why one is more prone to have the nightmare when lying on the back than when asleep otherwise is not known. The moment the position on the back was assumed he has been moved by the attendants on the side. They say that he has not had the attacks so frequently as before. He, himself, does not think that he would have the attacks as hard if he could sleep all night through on his side. He should get a case for himself. He should get a first-class coffin constructed of two boards,

one to press on his back and the other for the front part of the body, so that it will be impossible for him to get on the back. As you know, the attack which he had this morning came on while he was sitting up, so that I do not anticipate that he will derive very much benefit from lying on his side. It will certainly not cure him, absolutely.

As to the medical treatment, I hardly know what to give the man, as he has tried the bromide of potassium, chloral, and arsenic, without benefit.

In all these obscure cases you should have the passages from the bowels watched, as occasionally you find the cause of the trouble to be rectal irritation by a parasite. I remember a physician who was treated for mastoid pains, where he was cut and blistered, the periosteum scraped, and there was talk of trephining. Finally he came to me. I had his stools examined, and found that he had tape-worm. The parasite was gotten rid of, and the mastoid pains were cured. Such cases do not occur often, but only occasionally.

To sleep during the day and to be watched constantly, to be well douched the moment there is evidence of the paroxysm, to be careful about food, not to eat anything within six hours of his bedtime, to have his passages watched,—this is briefly the outline of the treatment.

TRANSLATIONS.

THE LOCALIZATION OF MOTOR LESIONS IN THE CEREBRAL CORTEX.—From a careful analysis of a long series of clinical cases Messrs. Charcot and Pitres draw the following conclusions as to the production of motor lesions in disease of the cerebral cortex in man:

1. All the cortical lesions of the cerebral hemispheres in man do not give rise to disturbances of voluntary motion. In this special point of view the cerebral cortex may be divided into two distinct districts,—the *non-motor zone*, whose destruction never produces permanent paralysis, and the *motor zone*, in which destructive lesions always produce permanent paralysis on the opposite side of the body.

2. The non-motor zone includes—1, all the pre-frontal region of the brain (orbital lobe and first, second, and third frontal convolutions); 2, the entire occipito-pari-

etal region (the occipital lobe and the superior and inferior parietal lobules); and, 3, all the temporo-sphenoidal lobe.

3. The motor zone includes solely the frontal and ascending parietal convolutions and the paracentral lobule.

4. Paralyses produced by destructive cortical lesions have different clinical characteristics according to the seat and extent of the lesions. Total hemiplegias of cortical origin are produced by extensive lesions of the ascending convolutions; partial palsies are produced by limited destruction of the same localities.

Among these partial paralyses, or monoplegias, the following may be recognized:

a. Brachio-facial monoplegias, which coincide with lesions of the inferior half of the ascending convolutions; *b.* Brachio-crural monoplegias, depending upon lesions of the upper half of the ascending convolutions; *c.* Facial and lingual monoplegias, which depend upon very limited lesions of the inferior extremity of the motor zone, and particularly of the ascending frontal; *d.* Brachial monoplegias depend upon very limited lesions of the middle portion of the motor zone, particularly of the middle third of the ascending frontal; *e.* Crural monoplegias depend upon very limited lesions of the paracentral lobule.

5. Whether total or partial, paralyses produced by destructive cortical lesions are permanent, and, after a certain time, are accompanied by secondary *contracture* of the palsied muscles and descending degeneration of the pyramidal strands.

6. Irritative lesions of the cortex may cause epileptiform convulsions (partial, Jacksonian, or cortical epilepsy). Such convulsions may be very readily distinguished from true epilepsy, as they originate with a motor aura, and may be either general or confined to one-half the body (hemispasm) or to a single group of muscles (monospasm).

7. As a rule, lesions capable of producing epileptiform convulsions are situated in the neighborhood of that cortical region whose destruction would produce paralysis in the muscles first affected. The causative lesions may, however, be found either in the motor or the non-motor zone, and no such definite relation between the character of the epilepsy and the location of the cortical lesion can be fixed as exists between paralyses of cortical origin and the lesions producing them.

8. The history of motor localizations in man is founded upon the comparison of many hundreds of concordant and careful observations. There is not one of the facts regarded as opposed to the doctrine of cerebral localization but is open to criticism; there is not a single opposing fact capable of demonstration. All the observations reported as disproving the fact of localization are unreliable, either on account of the complex nature of the lesion (multiple lesions, effusions, tumors, etc.) or because unaccompanied by sufficient details.—*Revue de Médecine*, October 10, 1883.

THE PERCENTAGE OF CHLOROFORM IN THE BLOOD OF AN ANÆSTHETIZED ANIMAL.—MM. Grébaut and Quinquand have determined the percentage of chloroform in the blood of an animal narcotized by that agent, by distilling in vacuo the chloroform from the blood, and then determining its percentage by the power possessed by the chloroform of reducing the cupropotassic test, in the same way as the percentage of sugar is determined in a liquid, it having been found that 18.7 C.c. of a solution containing 0.005 grm. of chloroform will reduce 0.3 C.c. of Barreswil's solution.

In seven experiments conducted after this method they found that the average quantity of chloroform present was 1 grm. for every 2000 C.c. of blood, the actual figures ranging from 1800 to 2181 C.c. From this they conclude that the anæsthetic dose of chloroform is 1 grm. of chloroform for every two litres of blood, or $\frac{1}{2000}$.

Other analyses have shown that the fatal dose of chloroform is extremely near to the anæsthetic dose,—an additional fact pointing to the danger of employing chloroform as an anæsthetic agent.—*La France Médicale*, October 13, 1883.

THE USE OF ATROPINE IN CORYZA.—The power possessed by atropine of diminishing the secretion of the nasal mucous membrane led Gentilhomme to employ it in acute coryza. In several severe cases, characterized by profuse secretion, fever, and difficulty of breathing, which in one case closely resembled asthma, one-half milligram of atropine given in pill form served to arrest the disease entirely. When the disease has passed through the acute stage, its administration improves the gen-

eral condition, but its effect is not as striking as when given in the acute stage. Lublinski also reports decided improvement resulting from the administration of one milligram of the sulphate of atropine at the onset of acute coryza, and the duration of the disease appears to be considerably reduced by the administration two or three times daily of one-half to one milligram. In chronic nasal catarrh, however, he could not find any improvement resulting from this treatment.—*Deutsche Med. Zeit.*, October 11, 1883.

THE PATHOGENIC IMPORT OF TUBERCLE-BACILLI.—After a series of culture and inoculation experiments, made in conjunction with Dr. Arndt, in Königsberg, Dr. P. Baumgarten concludes that it is the peculiar bacteria discovered by Dr. Koch and himself which call the tubercular process into existence. If it be urged that the contagion does not exist in the bacilli but is simply associated with them, he would reply that from the experiments it is evident that this hypothetical extra-bacillar virus is so intimately bound to the bacilli that it acts only with them and through them, since the disease may be caused by bacilli artificially cultivated in albuminous material, in which they are capable of infinite increase without losing this hypothetical infection.—*Centralblatt für Medicinischen Wissenschaften*, No. 42.

THE USE OF METALLIC MERCURY IN INTESTINAL OCCLUSIONS.—The old practice of administering metallic mercury for volvulus has been revived by Dr. Bettelheim, who reports seventy cases of intestinal stenosis treated by this method: fifty-seven were entirely relieved by its use alone, and in none of the seventy were there any bad effects noticed. In six cases the remedy saved the lives of the patients. It is claimed that it acts promptly and efficiently, without any of the inconveniences which have been attributed to it.—*Deutsches Archiv für Klin. Med.*, and *Paris Medical*.

TRICHLORACETIC ACID IN URINE-ANALYSIS.—Raade proposes the use of trichloroacetic acid as a test for albumen in the urine, used in place of the nitric acid in Gmelin's test, and in the same manner.

BROMIDROSIS PEDUM.—The subnitrate of bismuth is recommended for offensive sweating of the feet by Dr. Vieusse, of Algeria.—*Gazette Hebdomadaire*.

EDITORIAL.

THE ETIOLOGY OF HAY-FEVER.

THERE have been within the past two or three years a number of contributions to medical literature upon topics indirectly connected with the subject of hay-fever, which combine to throw some additional light upon the pathology of this, in many respects, peculiar disease. The publications of the Hay-Fever Association, and especially of two of its members, Dr. Morrill Wyman, of Boston, and the late Dr. George M. Beard, of New York, had already shown very definitely the geographical distribution of the disorder, and demonstrated conclusively that residence in certain places before and during the period of the customary attacks will confer complete immunity from them. To the well-known resorts in the White Mountains and on the sea-shore, might be added several that deserve to be better known in Pennsylvania: prominent among which is Kane, in McKean County, situated at the highest point attained by the Philadelphia and Erie Railroad in crossing the Alleghany Mountains. From personal experience, we know that this spot is constantly visited by hay-fever victims, who, while there, remain free from manifestations of the disease.

Although experience and observation had apparently established the fact that the immediate cause of hay-fever is contained in the atmospheric air of certain localities, we have the testimony of Dr. J. O. Roe, of Rochester, that in many hay-fever patients there may be found hypertrophies of the nasal mucous membrane; and he also reports cases* in which there was complete

immunity from subsequent attacks conferred by removal of the hypertrophies over the turbinated bones.

On the other hand, a medical correspondent of the *Chicago Tribune*† very positively declares that the cause of the catarrhal symptoms "is not, after all, hay, grain, or the rose, or the peach, but the beautiful and widely-worshipped golden-rod, whose burr-like pollen-cells are especially adapted for the rôle of local irritants of the mucous membrane of the upper air-passages;" and he claims that these cells are carried into the nostrils through the agency of minute aphides. The correspondent considers these insects as the real cause of the disease, and recommends examination of the secretions, in order to discover if they contain their ova or larvæ. He suggests that some analogy may exist between intestinal worms and these parasites, and says that a diseased condition from such a cause "seems as reasonable as that from the presence of ascarides in other mucous surfaces."

Blackley, in his classical work,‡ declares, however, that, whatever might be the nature of the influences which modify the activity or power of pollen in producing hay-fever, this power was always present, in a greater or less degree, in all the plants he experimented with. In other words, since pollen of various kinds may cause the disease, it has no specific poison, whether vegetable or animal. We recall, in this connection, the fact that the microscopic investigations made by Prof. Leidy§ failed to demonstrate any specific cause for the disease.

In a communication to the last meeting of the American Laryngological Association, Dr. John R. Mackenzie, of Baltimore, claimed that he had discovered a nasal reflex centre for cough, in the mu-

† Republished in Fort Wayne Journal of Medical Sciences, October, 1883.

‡ Experimental Researches on the Causes and Nature of Catarrhus Æstivus. London, 1873.

* Transactions of American Laryngological Association.

cous membrane of the upper portion of the septum, within a well-defined area. When this centre was irritated, whether by a foreign substance, or by a turbinate hypertrophy, or by the touch of the experimenter, cough was immediately produced, —in some persons more decidedly than in others; thus corresponding perfectly with the well-known ear-cough. Combining this with the foregoing, it would seem that this discovery throws more illumination upon the cause of hay-fever than we had before.

The fact of the existence of a personal idiosyncrasy with regard to this disease, as asserted by Phoebus, of Giessen, has been repeatedly observed. This may be explained, in part at least, by the discovery made by Dr. Roe of the existence of antecedent local disease. The fact of the necessity of the presence of an aerial agency in its causation also is demonstrated both by its geographical distribution and by experiment. The *modus operandi* of the particular irritant in each case and the mode of production of the peculiar symptoms are explained to a certain extent by the discovery made by Dr. Mackenzie. Hay-fever, then, is a peculiar catarrhal affection of the upper air-passages and associated regions, with a strong neurotic element (as shown by the paroxysms of coughing and sneezing, the sudden onset of the disease, and its occurrence principally among the higher classes and in persons who lead sedentary lives). It does not occur in all persons, but one attack predisposes to future attacks; and, although occasioned by various forms of irritants, certain individuals may be obnoxious to only one variety of irritant.

The treatment to be pursued is either to change the residence, so as to remove the patient from the sphere of activity of the special irritant in his particular case, or, as far as may be possible, to render him insusceptible to the action of the irritant by local measures to the upper air-passages:

possibly by the use of a respirator and the application of detergent alkaline and antiseptic sprays to the inflamed mucous membrane, and other similar symptomatic means, until the period of the prevalence of the disorder has passed away.

HOMICIDE SECUNDUM ARTEM.

A PROMINENT physician of this city some years ago was called to see a young colored man who presented the usual symptoms of hydrophobia, and he gave the diagnosis accordingly. Returning some hours later, he found, to his great astonishment, that some of the neighbors had gathered in the room and were preparing to smother the patient with a large feather bed, which they considered the proper and the only thing to be done under the circumstances. These ignorant colored people, however, did not stand alone in the idea that when a person has hydrophobia it is both right and proper to put him out of his misery *secundum artem*. That this opinion is so wide-spread, and really not confined to the lowest classes in the community, suggests the horrible thought that other cases have occurred, and possibly not without the sanction of some ignorant but well-meaning physician. There is also a very common notion that an accoucheur on finding that an infant is deformed, or is a monstrosity, has a right to deny it proper care and to destroy it. As the ranks of the profession are recruited from those of the laity, and not always from the most intelligent and cultured portion of it, popular errors are thus liable to enter and be perpetuated in practice. This probably is the reason why proprietary medicines are still prescribed by some physicians, who thus betray a kind of atavism, by the persistence of ante-natal modes of thought not derived from their Alma Mater.

Some recent communications to medical journals seem to invite discussion of the question of the right of a physician deliberately to destroy life in another human

being, when his own life is not in danger. Two of them show such a misappreciation of the duties and privileges of the medical attendant that we cannot refrain from mentioning them. A correspondent of the *Boston Medical and Surgical Journal* inquires as to the duty of a physician when a monstrosity is born, whether or not it shall be suffered to live, and states that his preceptor had told him that it had been invariably his habit to destroy all such monstrosities occurring in his own practice! But a more remarkable case is one by D. Scott, M.D., of Pierre, Dakota, in the latest issue of the *Chicago Medical Journal and Examiner*. The patient was a man about 40 years of age, a pauper, living—or rather dying—alone in a cabin, covered by filth and flies. Obeying the direction of the commissioners of the county, Dr. Scott saw the man, who was in a terrible condition, the result of ser-piginous phagedæna, which in its course had destroyed the external genitalia and had spread into a large ulcer from the perineal to the hypogastric region. The reporter asks, "What was the duty of the conscientious physician under the circumstances?" By a curious interpretation of the golden rule, he concluded to give him "a teaspoonful of Magendie's solution of morphia, which carried him rapidly into peaceful oblivion and final euthanasia twelve hours later."

Probably the poor man would not have survived very long at the best; but the physician, in his account of the case, does not appear to entertain any doubt of his possessing the right to dispense euthanasia. Some allowance, of course, must be made for the fact that the case was on the borderline of civilization, where proper conveniences for treatment were not at hand; but we fear that even the benevolent intentions of the one who offers a patient the happy release will not make killing anything but homicide in the eyes of the law.

NOTES FROM SPECIAL CORRESPONDENTS.

COLUMBUS, OHIO.

MEDICAL ETHICS "OUT WEST."

THERE is no provincialism so narrow and hopeless as that which may be found in a metropolis. A metropolitan, finding in his city everything that he wishes, and caring nothing for an acquaintance with the outside world, may live in his microcosm in contented ignorance. *Per contra*, the real provincial has many wants which bring him in person or vicariously to the metropolis, and he soon comes to know what is going on there as well as at home. It is, therefore, true, even if paradoxical, that one may find higher examples of culture in country towns than in great cities. This rambling beginning is intended to point a moral later on.

When metropolitan indifference gives way to enterprise, some queer things occasionally happen, as is abundantly illustrated in the literature of travel. A journey by a citizen through countries unfamiliar and which he has thought of before only with contempt, when put on record, is always amusing, if not instructive.

For instance: The Metropolis (with a capital M) has recently been enlightened by a wandering luminary of the *Medical Record* concerning the West,—more specifically, the great Northwest. The correspondent takes occasion to make some remarks upon "the Western medico generally," from which we extract the following gem: "Our Western confrère has perhaps heard of the Code,—in rare instances he has even read it some,—that is, the old one,—but he does not hanker after it. Nevertheless, he tries to lead the life of a gentleman." He feels satisfied that he can do this through the prompting power of his own impulses: hence he cares little for the old Code, and just about as much for the new one. He upholds regularity, especially in the matter of sending bills, yet he rarely hesitates to meet his homœopathic brother,—openly, as they do most things out there in that benighted West, not on the sly, as they do some things down here." I need scarcely say that this is untrue—to speak mildly. The action taken with reference to the New York insurgents (in the matter of the Code) in the last two meetings of the American Medical Association very clearly shows the attitude of the Western medical mind to the Code, for the dominant element in the Association is Western, at least in point of numbers. Having a fair acquaintance with the profession in Ohio, I can assure you that I know of no reputable practitioner who violates the Code.

Travellers should be careful in selecting their company, if they desire to give truthful pictures of the best society in any country.

STATE BOARD OF HEALTH.

There are rumors abroad that a more determined effort than any hitherto attempted is to be made during the coming winter to establish a Board of Health in Ohio. The excellent results achieved in other States make it a matter of wonder that the three leading States of the Union should be so backward in this matter. There are here many factors which stand in the way. Ohio has always had her full share of irregular practitioners, and since Illinois and West Virginia have dumped the greater part of their refuse into the State, this element has become larger and more important in the eye of the politician.

We have also nine regular medical colleges, a number sufficient to insure active competition and create a suspicion of mutual jealousy not favorable to harmonious action in any direction. When we add to this the intense ignorance of the average legislator in matters of hygiene and medicine, we see that such a movement has much resistance to encounter, both aggressive and passive.

TYPHOID AND MALARIAL FEVERS.

In this part of the world we are at present having quite a number of cases of typhoid fever with malarial complications, a condition attended with some puzzling symptoms. Occasionally a patient who has been exposed to the cause of typhoid will contract a malarial poisoning during the incubative period. The physician naturally makes a diagnosis of remittent fever, treats the patient with calomel and quinine, and a considerable improvement follows, including a reduction of temperature. But forthwith the typhoid symptoms supervene, and the patient, having been already enfeebled by his wrestling with the malarial fever, is in no condition to encounter the next enemy with advantage. It would seem that the "*bacillus ilio typho-phyton*" is an entirely different bird from the *bacillus malariae*, since what is poison to one appears to be meat for the other. Uncomplicated typhoid is here, as elsewhere, a comparatively mild and manageable disorder.

The Central Ohio Medical Society, a vigorous institution, meets here monthly. I hope to furnish you, hereafter, with some account of its doings.

November 8, 1883.

COLON.

ST. PAUL, MINNESOTA.

A THREE weeks' sojourn in this city has given me exceptional opportunities of observing medical matters here and in the more youthful city of Minneapolis, only ten miles distant. To one whose life has been mostly spent in the settled and dignified cities of the East and South, the rapid growth of the

newer Western communities presents itself as something quite extraordinary. Since my arrival here, I have conversed with a number of persons who are still in the full vigor of life, and who yet remember when this city of one hundred thousand inhabitants, with its electric lights, its telephones, its eight-page newspapers, and its prospective million-dollar hotel, was but a trading-post of two buildings. The prominent men in political, mercantile, or professional life are nearly all under forty years of age. As examples drawn from the medical profession, the most widely known gynæcologist in the Northwest is hardly over thirty-six, the best surgeon is less than thirty-two, the most successful oculist is certainly under thirty-five, while the mass of the profession is probably not out of the twenties. As in the medical, so in the legal profession and in mercantile life, the young men are at the front, and it looks mightily as if they intended to stay there. Already I have heard "old" physicians of thirty-five talking of giving way in a few years to the younger men who are coming to the fore and will soon supplant their youthful seniors!

In the East one often consoles himself, when things go awry, with the comforting fiction that the West is a wild place, where all sorts of wickedness run riot in a bold and law-defying course, and that one must "rough it" there, and be one of the *hói polloi*, if one desires to get along at all. So far as St. Paul is concerned, nothing is further from the truth. Everything that can be desired in the way of culture and comfort can be had here, and it is generally paid for at pretty lavish rates, considered from the economical stand-point of the East.

The medical profession of St. Paul is, taken altogether, the most harmonious in sentiment and helpful in mutual service that I have found anywhere in this country; and I can establish the claim of being somewhat of a traveller. I have had the opportunity of meeting all the regular physicians of the city, with very few exceptions, at a reception given by one of the most prominent and successful men here, and have had quite abundant opportunities otherwise of judging. Nothing can exceed the courtesy with which they treat each other. Ethical questions seem to disturb them very little, because most of them observe the strictest ethical propriety in their professional relations. Some of the specialists, I am told, did adopt questionable means to bring them into notice, but the "Oculist and Aurist" sign disappeared after a little coaxing. Personal feeling is kept entirely in the background, and no evidence of it ever crops out publicly. Even in the placid professional life of Philadelphia the personal element is more pronounced than here. This does not mean that the medical men here are a weak set, who get along peaceably for lack of self-assertion. Far from it. In physical, mental,

and doubtless in moral attainments, the St. Paul physicians compare very favorably with the profession in any of the large cities of the country.

At the last session of the Minnesota Legislature, a medical bill was passed creating a State Board of Medical Examiners. The law is modelled after the Illinois and West Virginia laws, and goes into effect on the 1st of next January. The quacks who are threatened by the law are preparing to move farther West, or perhaps back to the more tolerant East.

In the cities of St. Paul and Minneapolis very stringent health ordinances exist relating to the notification of infectious diseases. In some cases neglect on the part of the physician has resulted in arrest and fine. Houses in which smallpox, diphtheria, or scarlet fever exist are placarded by the health department, and public funerals in cases of infectious diseases are prohibited.

The State has a well-organized Board of Health, whose work compares very favorably with that of similar organizations elsewhere.

At the last meeting of the Ramsey County Medical Society,—which is the St. Paul branch of the State Society,—Prof. C. A. Wheaton exhibited a patient upon whom he had performed amputation at the hip-joint for necrosis of the femur. The removed bone was also shown, and was the most beautiful specimen of the sort I ever saw. After the relation of other cases, Dr. Schulin read a very excellent paper on the use of jequirity in granular lids. The author's results, after considerable experience with the remedy, agreed with those obtained by De Wecker, Sattler, and others.

The Minnesota College Hospital is in advance of most of the larger Eastern schools in insisting upon a preliminary examination and a three years' course. The class is moderate in size,—between fifty and sixty,—but seems to be composed of good material. The Faculty is composed almost equally of St. Paul and Minneapolis men, and is mostly made up of well-informed men and good teachers. In due time the weaker elements will disappear, and be replaced by others better qualified. The hospital facilities are excellent, and the institution deserves, as it will doubtless achieve, success.

The social qualities of the medical men here are doubtless remembered with pleasure by the members of the American Medical Association who attended the meeting of last year. I can echo the sentiment I then heard so generally expressed, that the St. Paul physicians are "good fellows, all." I never spent three pleasanter weeks in my life than those which gave me the opportunities to make the observations just recorded.

CORSAIR.

CORRESPONDENCE.

LONDON LETTER.

THE session is quietly progressing, and nothing is going on unusual or surprising. The ordinary number of peers are ill, and the usual array of medical names are found in attendance upon them, as the columns of the daily press tell us. The Archbishop of Canterbury has had an operation performed upon his rectum, a matter which it seems "it was requisite for special reasons should not be misunderstood or misrepresented." I suppose if the commander-in-chief of the British army happened to require an operation for stricture, there might be found "special reasons" why it should not be "misunderstood or misrepresented." I was brought up to regard the maladies of patients, especially those connected with what was the one cloacal opening of the lower forms of life, even when divided into two, as strictly matters for privacy. But *tempora mutantur*, and—must it be added?—*nos mutamur in illis*. It is a strange tale of upheaval of old notions if it is so. What makes it still more curious about the primate's illness is, "Those most interested wished that the whole truth should be known, and that there should be no secrecy in the matter." If publicity is desired by those most interested, of course no secrecy on the part of the medical attendant could be either desired or insisted upon; but if "those most interested" in one case desire publicity, in that case it is breaking down the old rule, and makes the old-fashioned secrecy, instead of being, outside all question or consideration, a matter of course, now a matter on which the patient and his family must be formally consulted in such cases. The tendency will be to embarrass the relations of those exalted personages who figure in the newspapers, and their medical advisers. Fancy, if an elderly nobleman were to be operated upon for an anal fistula, his surgeon having to ask, "How many of the details would your lordship like to have inserted in the published report,—the mere length of it, or more minute details as to the manner of operation and how your lordship bore it?" Yet it would seem that this is what we are in some danger of coming to, if the desire for publicity becomes too strong for decency: it has some time ago overstepped propriety. The present primate has been rather weak in his parade of his position, but this ridiculous folly will simply provoke contempt. It is to be hoped, out of respect for his office, that he personally, though one of those most "interested," did not desire "that there should be no secrecy in the matter."

I have had occasion from time to time to subject matters connected with the British Medical Association to criticism which some might regard as sharp, and a smaller number

even hostile; but it is now my pleasant duty to relate something of it which is decidedly meritorious and calculated to be of the very highest utility. Some time ago the project was mooted of utilizing the vast numbers of the Association for collective investigation,—an excellent project. The waste of experience going on was felt to be a reproach. Hitherto observations and generalizations have been mainly the work of individuals rather even than of committees. “The advantages of this method are obvious, and it must continue a great means of advancing medical science; but it has the disadvantage of leading to a sort of imperialism or Cæsarism, and hence to the domination at particular periods of the dicta or dogmas of certain persons, and that prevalence of passion, that blind adoption of shifting views and modes of treatment, which tends much to repress thought and stifle inquiry.” Consequently, it was thought that “the collection of information upon a grand scale, which has the double effect of stimulating many investigators and of drawing facts from many sources, not as a substitute for, but as an addition to, individual research, has long been felt to be one means of meeting the difficulties and disadvantages just mentioned. It was obvious that the British Medical Association, with its enormous force of members, its *Journal*, its organization of branches, its funds gathered by good management and economy, afforded an opportunity such as had never existed before of doing it.” So a committee of some good men, metropolitan and provincial, was formed, who set to work. Addresses were given by Sir William Gull, Sir James Paget, and Professor Acland, giving great encouragement to the promoters of the scheme; “but the greatest encouragement of all has been the number of carefully-filled cards which have been received, especially on pneumonia, from the members of the Association living in the various districts of the country. For this shows not only a widely-extended perception of the need of the work, but the willingness of a large number to assist in carrying it out.” It was soon found, indeed, that the *Journal* must be relieved of much of the material, and a special report be issued.

As to the communicability of phthisis, a certain proportion of answers, amounting to the respectable total of two hundred and sixty-one, tell of this having been observed, while a smaller proportion, one hundred and five, actively negatived the view. Now, when so many men have observed a fact (if fact it be) so opposed to their professional teaching, even the stoutest advocate of the old view may be pardoned if his confidence in that view is a little shaken. That cases of communicated phthisis, distinct and unquestionable, can never form a large proportion of the total number of cases of the common malady is probable enough. Nor is, perhaps, the

scare on the subject in Germany following upon Koch's discovery of the bacillus of tubercle altogether without some permanent value in all probability. Bacilli are found in hordes in softening tubercle, I am credibly informed; and one of those most interested in the subject offers, with much complacency, to make myself the victim of phthisis if only he may place a sufficiency of the little villains in my veins: still, there is the family predisposition to be borne in mind. The contagiousness of pneumonia, of which there is some evidence, “striking if scanty,” is an aspect of that malady distinctly novel. The report on the treatment of acute gout will be interesting and instructive, if only negatively instructive. As to chorea, it was found, “with reference to *nervousness and nervous affections in the families of those suffering from chorea*, the returns supply information which strengthens the general opinion that the disease is especially apt to occur in families in which other nervous affections are common.” Arsenic seems to have been one of the main agents used in the treatment, with the result “varying success,” while sulphate of zinc seems often “to have been of striking utility.” As to acute rheumatism, the prevalence of fashion in the treatment of disease is demonstrated by the fact that salicylate of soda was the drug in most favor. From the report on diphtheria it would appear that sometimes the throat is comparatively little affected while the kidney-complications are proportionately severe. This fact certainly tends to show (to my judgment at least) that diphtheria is allied rather to scarlatina than to croup, and falls in with my personal experience in the past. A proposal to inquire into the association betwixt whooping-cough and measles is also suggested.

The subjects at present before the Association are—1, acute pneumonia; 2, chorea; 3, acute rheumatism; 4, diphtheria (clinical); 4a, diphtheria (sanitary); 5, syphilis (acquired); 5 a, syphilis (inherited); 6, acute gout; and a great deal of very useful information will probably be elicited on the various topics. How far the information obtained by collective investigation will harmonize with or clash with the opinions formed by individual observers remains to be seen. It will certainly stimulate those who are ambitious of being regarded as leaders in medicine to examine their views very closely when they see what views find acceptance with the profession, as indicated by these returns; while doubtless on the other hand many isolated facts will be gathered together, gleaned as it were by this collective inquiry, which will furnish material for comprehensive thinkers. From both of which much good will accrue and much thought be excited throughout the ranks of the profession.

An address recently delivered at the annual meeting of the Metropolitan Branch of the

British Medical Association, by Dr. Charles J. Hare, the President, and late Professor of Clinical Medicine in University College Hospital, has been reprinted by request. It is entitled "Good Remedies out of Fashion," and throws a most interesting light upon the change which has gone on in medicine during the last generation. Dr. Hare seems rather oppressed by the number of new remedies advertised for the liver and ending in "in." Then, deprecating the criticism of "younger members of the profession, who will look upon these things as some strange and new doctrine, or as prejudices clinging to me from my earlier days, or as antiquated customs of which the progress of modern science has shown the futility or wrongness," he plunges in. First he considers the subject of *milk*, now so largely given in all hospitals. Five-and-twenty years ago it was difficult to see a patient who had been in the hospital a few hours before one's visit who had not been already, and almost as a matter of course, put on three or four ounces of brandy by some resident assistant, a fashion against which he set his face at the time. He points to the fashion on the subject now, when alcohol is being tabooed very extensively. He collected statistics from our leading hospitals as to the amount of alcohol purchased then and now. At St. Bartholomew's Hospital, for instance, in 1852, wine and spirits cost £496; in 1862, £1231; in 1872, £1446; and in 1882 the sum of £953. The variation in other hospitals has been much the same. Milk has grown in demand: at St. Bartholomew's, in 1852, milk cost £684; in 1882, the sum of £2012; at Guy's, £236 and £1448 respectively; and at the London Hospital, £426 and £2427 respectively. These figures carry with them much material for thought and reflection. Yet in these hospitals there are many patients who are little more than broken-down drunkards. In a rural population probably less alcohol, even, would be given under like maladies.

Then he proceeded to speak of "Emetics." Not long ago he saw in consultation a case of suffocative bronchitis, and advised an emetic. The comment was, "Why, I never gave an emetic to an adult in all my life." It makes one feel a strange sensation of wonder to conceive where this medical man had got his college education, and what kind of an experience he had had in professional life. Dr. Hare then gives a sketch of the almost magical effects of an emetic in such bronchial condition. He then alluded to the composing effects of an emetic in delirium tremens. He then referred to a case where a corpulent lady of 34, who suffered from dyspeptic pains, and who was made worse by food, was relieved by vomiting, especially as to the nausea and headache. The vomited matter was always intensely acid. He soon satisfied himself that there was no organic disease of the stomach, and gave a scruple of ipecacuanha powder.

—*

After this she vomited freely a quantity of ropy mucus, intensely acid, and after that was *well!* In such cases he thinks there is present much morbid acid in the gastric follicles; a little was got rid of by each act of vomiting; but the emetic, followed by draughts of warm water, removed all the excess of acid, and so cured the patient.

He then spoke of the use of opium in "needless, useless coughing;" but, personally, I fear that a man with less than Dr. Hare's judgment might easily reduce the coughing to the stillness of death, if he followed his practice without the necessary discrimination. Used as Dr. Hare proposes, there is much to be said for such use of opium; but wielded indiscriminately I shudder at the consequences. Then he spoke a word for purgatives, now too much avoided from the fear of producing "debility." This word, he says, is "the *bête noire* of the present medical world." Then he quotes Byron: "Talk about champagne, there is nothing in the world cheers your spirits up like a dose of Epsom salts." Then a word or two followed about mercury as a cholagogue, and its great utility in melancholy,—the "black bile." Then follows a eulogium of the old attention to the *primæ viæ*, so little understood, and therefore so little attended to, at the present time. More aperients would mean fewer tonics, he opines. "Remove the cause, and the effect will cease," he holds, "and in many cases where it is little suspected, the cause of the varied symptoms lies in the morbid secretions in the *primæ viæ*, which have been long, perhaps, poisoning the system. If these be removed, there is, in a vast number of such cases, strength and 'spring' enough in the constitution to set all to rights without the aid of anything, or with the aid of but little in the way of tonics; and in many cases with the removal of the intestinal irritants the 'weakness' and 'debility' rapidly vanish." If this is not the old hydra-headed monster 'humoral pathology' rampant as ever, what is it? Ye men of the dead-house and the microscope, ye clinical men of stethoscope and pleximeter, do ye hear the prophet of the past speaking to you? Do ye heed? "Such fluctuations and such changes take place in opinion and in practice, in beliefs and actions, that it almost seems as if the results of the experience of ages, instead of being engraven on the rocks, were written on the sands, and that the wave of fashion, sweeping over these, at once obliterated the inscriptions which ought to have been indelible." Then follows a consideration of "blood-letting." Once no hospital was without its cupper, who visited daily to carry out the instructions of the physicians and surgeons. Where is he now? Gone, it is to be feared. Yet Dr. Hare thinks he might be useful still. Gone "with the dodo and the ichthyosaurus!" Then as to leeches. They have gone too. In 1842 the cost of leeches at

St. George's Hospital was £141; in 1852, £38; in 1862, £5; in 1872, £2 14s., and in 1882, £2 13s. 6d.; while at the London Hospital leeches cost in 1839, £495; in 1842, only £180; and in 1872, £5 10s. A once large leech-importing firm now do not think it worth while to keep any account of leeches, their sale not amounting to fifty yearly. Dr. Hare eschews any intention of advocating a return to the old days of "the almost indiscriminate use of bleeding;" but the abuse of a thing is no argument against its use. He then showed a friend of his who in 1829 had a fit, for which he was bled repeatedly with good effects. After a time the fits returned, and he was bled again, and freely, and leeches too. Yet, so far from debility being produced then or since, the gentleman was a very hale specimen of an old man. He told of the good of bleeding in pneumonia; of its almost magical effects in pleurisy. Then the engorged right ventricle came in for its share of consideration, and a graphic picture is drawn of the good effects of bleeding. As the black, tarry blood begins to flow at first only with the greatest difficulty, then more freely, the relief is almost beyond conception. As I read the description, the words of my father and others of the past generation seem to be once more ringing in my ears with a quite familiar sound. Then "the choked-up heart is set free."

Dr. Hare disclaims in this any "fancy picture," and appeals to the senior portion of his audience for the corroboration of his words. He then tells of a case of a girl of fourteen, who had head-symptoms from over-study. Leeches gave relief, so that she could leave her bed. During thirteen weeks she was ill, and in that time was seen by three of the most eminent F.R.C.P.s, not one of whom gave a thought to leeches. Bromides were given, with some counter-irritation. At last Dr. Hare determined to do his own way. "On February 17, therefore, five leeches were again applied to one of the temples, and somewhat later the same number was repeated. The first of these applications gave the first relief the patient had to the coronet of pain which had been so long her constant companion; but, though greatly relieved, it was not cured. The second of these applications (the fourth of the series) entirely removed it, and the girl, once more bright and cheerful, returned to school, and has not since been an hour absent from her duties." Another picture, most forcibly drawn, was given of the effect of leeching in acute meningitis. Dry cupping came in for its word in the retrospect, and then the doctor made his *congé* and took his leave of his hearers, who seem to have listened to the voice of one of our master-spirits long ago gone over to the majority, who had come back to tell us that all our recent advances have not been progress. There is much in the past which has been neglected and almost forgotten which is well

worth digging up, and "voices from the dead" will, it is to be hoped, from time to time waken us up as a not unnecessary or undesirable attention. Are we not nodding in a complacent, self-satisfied snooze very often, even in what we hold this wide-awake age? Dr. Hare, and those who think with him, would seem to be of some such opinion.

J. MILNER FOTHERGILL.

PROCEEDINGS OF SOCIETIES.

AMERICAN PUBLIC HEALTH ASSOCIATION.

THE eleventh annual meeting of the American Public Health Association, held at Detroit, Michigan, which closed November 16, was one of the most successful in the history of the Association. The subjects discussed were practical, and the majority of the papers read were of more than average value. Business was dispatched with commendable speed, owing to an efficient Executive Committee, and the duties of presiding officer were performed with dignity and grace by Dr. E. M. Hunt.

The proceedings of the first day comprised papers on the Texas Cattle-Fever, by Dr. Salmon, of the Agricultural Department; on Swine-Plague, by Dr. J. M. Partridge, of Indiana; and a report on Actinomycosis in cattle at the Chicago stock-yard, by Dr. William T. Belfield, which was accompanied by microscopic specimens of the appearance of the diseased tissues, and of the fungus *actinomycosis*,—the cause of the disease. Dr. Salmon's paper was very elaborate, and considered the question very fully, whether the disease called "Texas fever" was really a specific disease of cattle, or whether a number of widely-different affections were included under this name. The conclusion arrived at, after a thorough sifting of the evidence, was that Texas fever is an acute, contagious, specific disease of cattle, that it is endemic in Texas and other parts of the Southern United States, and that it may be, and is frequently, spread by contagion to other parts of the country. The paper deserves the careful study of all sanitary officers and stock-raisers. The report of Dr. Belfield on actinomycosis is of especial interest as being the first exact contribution to our knowledge of the disease made in America. As actinomycosis is communicable to man, and is invariably fatal in the latter, the value of his observations is apparent. The common name for the disease in cattle is "swell-head," or "lumpy mouth," from the characteristic lesion, a series of tumors of the upper jaw, which on examination with a microscope show a fungus consisting of club-shaped rods radiating from a common centre. The af-

fected animals lose flesh, and eventually die with symptoms resembling pyæmia.

The discussion on malaria was opened with a paper on its etiology by Dr. G. M. Sternberg, U.S.A. This paper was followed by equally elaborate ones from Surgeons A. A. Woodhull and Charles Smart, also of the army. Dr. Sternberg's researches, statistical and otherwise, showed that the cause of malarial fevers was not produced in the absence of heat, moisture, and vegetable decomposition. The intimate nature of the cause he did not attempt to elucidate. Dr. Woodhull's views were nearly similar to those arrived at by Dr. Sternberg, while Dr. Smart struck a more practical chord by showing that malarial diseases could be caused by polluted drinking-water, and urging the necessity of more frequent and thorough analysis of drinking-waters, in order that the immediate cause of malaria might be discovered.

The discussion revealed a singular want of definiteness of opinion as to the nature and cause of malaria among those taking part in the debate. Several members, however,—among them Dr. Rohé, of Baltimore, Col. George E. Waring, of Newport, and Dr. Wight, of Detroit,—pointed out the relation of the motions of the ground-air and ground-water to the spread of malarial diseases.

In the evening a brief address of welcome, full of good sense and good humor, was delivered by the Governor of the State, who was followed by Dr. Brodie, of Detroit, and Dr. John Avery, President of the Michigan State Board of Health. The President, Dr. Hunt, then delivered his annual address. Dr. Hunt sketched briefly the origin and progress of the Association, giving a concise account of the advancement of sanitary science since its organization, and the Association's share in producing the advancement. The address was scholarly in matter, eloquent in manner, and gracefully delivered. Although occupying over an hour in delivery, it was listened to with close attention by the large audience present.

The inevitable paper on Yellow Fever appeared on the second day's programme, but was quickly disposed of, and the Association proceeded to the discussion of more profitable matters. The Adulteration of Foods was discussed by Drs. W. K. Newton, of Paterson, New Jersey, Prof. A. R. Leeds, of Hoboken, and Profs. Kedzie and Vaughan, of Michigan. The only thing clearly brought out was that laws against adulteration were of comparatively little use, because they were not properly enforced.

An excellent paper was read on the Hygiene of Schools, by Dr. C. J. Lundy, of Detroit. It was discussed by Dr. A. N. Bell, of Brooklyn, and Dr. Jones, of Massachusetts.

In the evening, addresses on Physical Training were made by Prof. J. Madison Watson, of New Jersey, and Prof. Sargent, of Cam-

bridge, Mass. The advantages of the various systems of physical culture were clearly explained, and its importance as a part of the school curriculum was strongly urged.

Dr. James E. Reeves, Secretary of the West Virginia Board of Health, delivered an excellent address on the Usefulness of State Boards of Health in Guarding the Public Welfare. It presented in a clear light the importance of sanitary organizations, and a becoming pride was expressed by the speaker in the advanced position held by his own State. The feature of the West Virginia law regulating the practice of medicine was explained, and an exposure of what looks like a bit of very sharp practice on the part of one of the medical schools of the Southwest was made to give spice to the entertainment. Dr. Reeves apparently has little hope for reform on the part of those States lying in proximity to the borders of his own State, for he says, "Little West Virginia, nestled in the mountains, and looking into the near future for the coming time when her inexhaustible stores of native wealth shall be unlocked to hundreds of thousands of busy laborers, has proudly acknowledged allegiance to the goddess Hygeia, under whose health-inspiring banner she has already won substantial victories and benefits for the saving of her citizens. But, while flushed with the stimulus of her triumphs, she turns in sadness and with outstretched arms and pleading voice to her elder sisters by whom she is immediately surrounded,—Ohio, Pennsylvania, Maryland, and the dear old Mother State,—and says to them, 'How long, oh, how long shall the land which the Lord thy God giveth thee be the *Paradise of quacks*?' "

The questions of sewage removal and final disposal, the ventilation and proper construction of sewers and water-closets, were discussed by Drs. J. H. Raymond and Bell, of Brooklyn, Mr. R. Herring, C.E., of New York, Dr. Oldright, of Canada, Col. Waring, and others, who by study and experience were able to contribute to a more thorough knowledge of the subjects under discussion.

The Increase of Insanity in the United States was the subject of an able paper by Dr. Foster Pratt, of the Michigan State Board of Health, read as the closing paper of the meeting. The author showed that the percentage of insane of foreign birth in this country largely exceeded the percentage of the native insane. He advocated the passage of laws to prevent the immigration of insane persons, paupers, and criminals from foreign countries. Resolutions praying Congress to pass such laws were adopted by the Association.

The officers elected for the current year are—

President, Dr. A. L. Gihon, Medical Director U. S. Navy.

First Vice-President, Dr. James E. Reeves, of West Virginia.

Second Vice-President, Hon. Erastus Brooks, of New York.

Secretary, Dr. Irving A. Watson, of New Hampshire.

Treasurer, Dr. J. B. Lindsley, of Tennessee.

The next meeting of the Association will be held in St. Louis in October, 1884.

The local committee, under the chairmanship of Dr. Wm. Brodie, made it pleasant for every one by their attention to the comforts of the visitors.

CORSAIR.

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting of the Academy was held, November 15, 1883, FORDYCE BARKER, M.D., LL.D., President, in the chair.

The death of the late Dr. J. Marion Sims was announced by the Statistical Secretary.

THE PRESIDENT made the following remarks:

By the death of Dr. Marion Sims the Academy of Medicine, the profession of this city, and, I may well add, the profession of the country have lost their most original and brilliant genius in the department of surgical gynecology. This will be conceded by all. Had circumstances forced him to equal activity in other branches of surgery, his fertility and promptness in practical suggestion, his intuitive power of conception of new means to secure any desired result, his endowment of invention and wonderful mechanical adroitness, would undoubtedly have given him equal eminence in all its departments. No one can be compared with him in his own sphere, in which he achieved such great distinction, except the late Sir James Y. Simpson. An intimate relation with both for many years may, perhaps, justify me in saying that there were very many points as to their intellectual and moral qualities which were strikingly characteristic of both. These resemblances were much more numerous than the points of contrast. In the future the greatest fame of one will rest on his courage, and I may even say audacity, in successfully introducing anæsthetics to relieve the agonies of parturition; in the other by his genius in devising new methods of physical exploration and new surgical procedures which effect cures of lesions which before could neither be correctly diagnosed nor successfully treated. In thus alluding to the greatest achievements of the two, I should also add, both were incessant, zealous workers, who for many years were constantly making positive contributions to our science and our art, many of which would alone establish their claim as great men in our profession; the former perhaps adding more to our scientific literature, and the latter more to the advancement of our art. Neither of them was reluctant to have his good work appreciated. To-

morrow morning, I doubt not, every Fellow of the Academy whose engagements will permit will be present at the funeral services of our late most eminent associate. The chair, in accordance with our by-laws, will designate Dr. T. Addis Emmet to read a memoir at the first meeting of the Academy in January.

TYPHOID FEVER IN NEW YORK.

Dr. FRANCIS DELAFIELD read the scientific communication of the evening, with the foregoing title. The statistics given were based on the cases treated in the several hospitals of this city during the past few years. By the tables of mortality of the Board of Health he had learned that for many years' past there had been an annual mortality from typhoid fever in the city of New York of from one to two hundred. From 1863 to 1866 the mortality ran up as high as five hundred to six hundred yearly during the time when typhus fever was also prevailing in the city. Since that time the yearly mortality had been from two hundred to four hundred; in 1879 it was one hundred and seventy-eight; in 1881 it was four hundred and forty-six; up to October 1, 1883, it had been two hundred and seventy-four. Most of the cases occurred in the latter part of summer and in early fall.

From the 1st of 1877 to October 1, 1883, thirteen hundred and five cases had been treated in the city hospitals. The percentage of mortality for these several years had been 27, 20, 30, 22, 23, and 26, respectively. Most of the cases were in adults between twenty and thirty years of age. But few children were received at the hospitals. There were many difficulties in the way of getting at the etiology.

At the autopsies the regular lesions, more or less marked, existed. The solitary and the agminated glands of the small intestines had been swollen, converted into ulcers; adherent sloughs were present, or the ulcers may have been cleaned off. The large amount of infiltration which occurred in some epidemics was not present. Perforation with peritonitis had occurred in but a small number of cases; the colon was but seldom involved, and in these the enlargement and sloughing of the solitary glands was marked. In one case multiple new growths of lymphatic tissue, with ulceration, occurred in the stomach; the mesenteric glands were swollen in a degree corresponding to the intestinal lesions. When unusually swollen, a little fibrin was present over the gland, and in one case the peritonitis had become general. Suppuration occurred in two cases. The spleen was soft and usually enlarged. In the case of a boy eight years of age it had ruptured, and hemorrhage had taken place into the peritoneal cavity. Inflammation of the colon existed in several cases and produced dysentery. In one the lower two-thirds of the colon were coated with fibrin. The liver was often enlarged.

Suppuration of the parotid did not occur. The kidneys showed swelling and degeneration of the epithelial cells, corresponding with the appearance of albumen in the urine, and sometimes of casts, during life. Flabby heart with degeneration of muscular fibre was present in but a few cases. The lungs were the seat of a variety of changes, as, congestion of the larger bronchi, in a few cases severe bronchitis and broncho-pneumonia, lobar pneumonia in two cases; a moderate degree of hypostatic congestion in the posterior portion of the lung was common. There was characteristic granular and waxy degeneration in the voluntary muscles, especially those of the anterior abdominal walls, in only a moderate proportion of the cases.

These notes were based upon one hundred and two cases of undoubted typhoid fever which had occurred in the hospitals during the past five years. During this time a number of cases of fever simulating that of typhoid had occurred. Of the one hundred and two cases there was a distinct prodromic period in only eighteen; languor, headache, indisposition to mental or physical labor, loss of appetite, constipation or diarrhoea, irregular chilliness, in some bronchitis. This period had varied from four days to several weeks. The invasion in thirty-seven out of the eighty-three cases in which the character was learned was a chill on the first day, either of a mild or more severe type; sometimes the chill was repeated, and was followed by febrile movement, often accompanied by headache, vomiting, and nose-bleed.

Diarrhoea.—Diarrhoea, accompanied by fever and sometimes by headache and epistaxis, was one of the first symptoms in twenty-five cases. There were forty-four cases in which diarrhoea was one of the first symptoms, in three of which blood was mixed with the passages during the first few days. Headache and fever marked the onset in fifteen, and in six bronchitis was a prominent feature during the first week. Pain over the abdomen, or in the right iliac fossa, existed in many of the cases. For various reasons, the record of the temperature could not be given in many cases for the first week. In those in which it was taken it did not follow the regular course which certain authors had laid down in the books. In some there was a morning chill, and afternoon fever and sweating; in some there were falls of the temperature, lasting for from six to twenty-four hours, during the first week. In the second week the temperature approached more nearly to the type of a continuous fever, with moderate morning remissions; in some the remissions were more decided; in some the morning temperature was the highest; in some it fell to normal by the fifteenth day, and convalescence began; in some the disease continued, the temperature again rising after a few hours. When a fatal termination took place in the second week

the temperature reached its highest point a few hours before death, or, if sooner, it fell to 101° or 100° just before death. The third-week temperature-record was much like that of the second. In the fourth there were more marked morning remissions. In some instances the temperature became lowered for a day or more, and then again rose. The height of the temperature was usually in proportion to the severity of the disease.

The pulse during the first week was regular, full, from ninety to one hundred, becoming more rapid and feeble in the second and third weeks. As a rule, the more rapid the more feeble the pulse. A rapid pulse was usually an unfavorable symptom. If a slow pulse was accompanied with cerebral symptoms, the case closely resembled cerebro-spinal meningitis.

The appearance of the patients was that usually seen in typhoid cases,—dulness of expression, dusky face, flushed cheeks, sluggishness of mind, tongue coated with white fur in the centre, afterwards becoming yellow-brown, sometimes becoming fissured. In some cases the tongue was comparatively clean; when it began to grow moist, convalescence might be considered as approaching. Active delirium was present in a number of cases, and was an indication of a severe form of the disease. Diarrhoea was present in eighty-two cases, beginning early in forty-four; in fifty-one it continued throughout the course of the disease. There was continuous constipation in eighteen cases, often associated with a marked degree of tympanites. The eruption was well marked in forty-four cases, and it had probably been overlooked in others. It had been more constant during the past autumn.

Complications.—Hemorrhage from the bowels took place in twenty-three cases, and was the direct cause of death in six. In two cases there was constant running away of blood from the rectum in the sixth week, as in cases of cancer, but no malignant disease was present. When hemorrhage occurred it was usually followed by a fall in the temperature. Only nine of the patients in whom hemorrhage occurred recovered. A pustular eruption of the skin occurred in one patient, but produced no other symptom than discomfort. Suppurative inflammation of the middle ear and discharge of pus in five cases; severe pharyngitis with false membrane in one during the first week; there was a moderate degree of catarrhal laryngitis in a number; bronchitis and a severe type of broncho-pneumonia in twenty-four, in sixteen of which it occurred during the first week. In three cases bronchitis seemed to have been the cause of death, lobar pneumonia in two cases proving fatal; repeated attacks of feeble heart-action and syncope in one patient; peritonitis in four cases, caused by perforation in two; thrombosis of the femoral vein in one; dysentery

after convalescence in five, proving fatal in one.

In one case convalescence began on the sixteenth day; in four, on the eighteenth; in six, at the end of the third week; in fifteen, in the fourth week; in twelve, in the fifth; in four, in the sixth; in four, in the seventh; in one, in the eighth; in nine, in the ninth; and in one case, in the tenth week.

There were well-marked relapses in seven cases. Out of the one hundred and two cases, thirty-four proved fatal; in eighteen, death seemed to be due to the typhoid disease. In the fatal cases the temperature usually ran high, from 104° to 107° , but not continuously so. The pulse was feeble and in most cases rapid.

In mild cases the patients were put to bed and given milk diet. Some of the hospitals employed peptonized milk; some physicians gave some form of alcohol in every case, by others it was reserved for feeble heart-action. Digitalis, convallaria, and caffeine were often employed as heart-stimulants. In some hospitals quinine was given to nearly every patient, in others only to reduce temperature, in others it was scarcely resorted to at all. The general bath of late had been almost entirely abandoned in the hospitals. Cold water, in the form of sponging or wet sheets, was still employed, more or less, for reducing the temperature. Turpentine, internally and externally, was commonly employed in tympanites. Opium and ergot were employed in intestinal hemorrhage. In diarrhœa, opium, with bismuth or pepsin, and a solution of acetate of aluminum, were mostly used. In one of the hospitals, if the patient was seen early, calomel was given with the hope of aborting the attack. Salicylate of sodium, benzoate of sodium, a combination of carbolic acid and tincture of iodine, with the idea of acting upon the poison of the disease, were seldom used.

THE PRESIDENT directed attention to certain points in the paper which he would be glad to hear discussed, and first called upon Dr. Alfred L. Loomis.

Dr. LOOMIS said that he had been interested to know what definition Dr. Delafield would give of typhoid fever. As the disease had been described by the author of the paper as prevailing in the city of New York at the present time and for some years past, one would hardly recognize the same condition, called typhoid fever, described by Liebermeister and other European writers. Those writers gave typhoid fever a typical range of temperature, gradually rising during the first week, remaining about even during the second, remittent during the third, intermittent during the fourth; as having a characteristic rose-colored eruption, which appeared between the sixth and the tenth day, each spot remaining three days, and then disappearing, perhaps to be replaced by another;

a pea-soup diarrhœa; the disease originating in a specific poison,—that is, from matter contaminated by the excrements of the typhoid patient. Such regularly characteristic symptoms had not been described by Dr. Delafield, nor had they regularly occurred in the cases of so-called typhoid fever which he had seen in the city the past few years.

Dr. F. P. KINNICUTT had examined the few fatal cases to which he had had access in the St. Luke's Hospital with regard to a possible relation between deep ulcers of the intestines and constipation, to which Sir William Jenner had first called attention. He thought that in those few cases such relationship seemed to have existed, and if so it had an important bearing upon the use of laxatives. It was best not to give laxatives by the mouth, but to employ an enema, one of small size, frequently repeated, being preferable to a large one. He was disposed to regard the relapses as due to the remains of the true typhoid poison within the system, rather than to accidental circumstances. His treatment consisted principally of rest in bed, plenty of pure air, a strictly-regulated diet, and medicinal treatment for special symptoms as they arose.

Dr. E. G. JANEWAY quoted the statistics of typhoid fever in New York City for more than a quarter of a century past, going to show that the disease was not increasing out of proportion to the increase of the population, as had been inferred. Typhoid fever was known to vary more or less in different epidemics, as was the case with other infectious diseases, and an atypical form had been described by European authors, and he therefore regarded the fever as it now prevailed in this city as true typhoid fever. The intestinal lesions were similar in the different fatal cases, although they varied in intensity, as did also the symptoms referable to such lesions. It might be difficult in given cases to trace the etiology, but he had often been able to do so, although at first it seemed impossible. To show the numerous opportunities for the germs to become spread, he referred to the case of a man, a peddler, who appeared at the hospital with typhoid fever, having had the symptoms thereof for more than a week, while going about at his occupation and during that time making use of the water-closets in the tenement-houses of the city. An estimate showed that in this manner he had possibly contaminated the water-closets of forty-eight different tenement-houses. In some epidemics the diarrhœal symptoms were more marked, in others constipation; and so of the other symptoms. He had found an eruption in nearly every case during the present fall.

Dr. T. A. MCBRIDE had employed kairine to reduce the temperature, giving it in seven-grain doses until the temperature fell to 101° , and then keeping it at that point by giving

frequently-repeated small doses. When so used, the drug produced no unpleasant symptoms, and was very effective. If omitted, the temperature would again almost immediately begin to rise.

THE PRESIDENT was usually averse to the employment of any drug which would disturb the bowels, but when constipation became uncomfortable to the patient he was in the habit of giving a single dose of five grains of calomel, well rubbed up with fifteen grains of bicarbonate of soda, with excellent results.

Dr. DELAFIELD, in closing the discussion, said that typhoid fever, like other diseases, showed a more or less varied course. The cases were not always of a typical kind, as described by Liebermeister. This author had been the cause of much misunderstanding by giving so positive and definite a course of the affection, such as did not exist in nature. He was in the habit of employing a laxative when constipation existed early in the disease, and with good effects.

NEW YORK PATHOLOGICAL SOCIETY.

A STATED meeting was held November 14, 1883, GEORGE F. SHRADY, M.D., President, in the chair.

TOOTH IN THE ANTRUM OF HIGHMORE.

Dr. J. A. WYETH presented one of the permanent teeth which he had removed from the antrum of Highmore in a woman 26 years of age, who had suffered from difficulty referred to that locality for about thirteen years, dating from an attack of measles or scarlet fever. A dentist had withdrawn a tooth, from the locality of which pus discharged from time to time for some years afterwards. Dr. Wyeth withdrew two of the teeth, and entered the antrum for the purpose of cleaning it and establishing drainage, when he came upon the foreign body in the form of a tooth. It was the only authenticated case of the kind of which he had any knowledge. He asked the members if they had had a similar experience.

EMBOLISM OF THE BASILAR ARTERY OF THE BRAIN.

Dr. G. L. PEABODY presented the heart and a portion of the brain removed from a man last spring. The patient had signs of heart- and kidney-lesions; had suffered from rheumatism; his mother had died of cardiac disease. He suffered from dyspnoea, cardiac palpitation, headache, anasarca, and a few hours before death became silly, and then very violent, requiring to be placed in the strait-jacket. The urine passed in twenty-four hours diminished to fourteen ounces. He died in a state of stupor. At the autopsy, cardiac hypertrophy and dilatation were present. The mitral valves were markedly thickened, stiff-

ened, and their surfaces rough. There was hemorrhagic infarction in one lung, and, just above, signs of acute pleurisy. The kidneys were the seat of extensive lesions. The parietal and the visceral layers of the pericardium were adherent. The basilar artery was found almost completely plugged with an embolus,—a condition which Dr. Peabody considered very rare. The rest of the brain, receiving its blood-supply through other channels, was healthy. The time of lodgment of the embolus probably corresponded to the time of development of delirium.

Dr. WYETH asked Dr. Peabody what he considered the immediate cause of death.

Dr. PEABODY thought it difficult to answer, for there were several conditions which might have produced immediate death.

Dr. WYETH asked the question because two cases of thrombus of the basilar artery had come under his observation in which death was attributed to anæmia of the pons and medulla, and there were other cases of the kind on record. At the time of the death of one of these patients he was contemplating ligature of the vertebral arteries in a case of epilepsy supposed to be due to miliary aneurism. He gave up the operation, because he feared voluntarily to produce a condition, namely, anæmia of the parts supplied by the vertebral arteries, which in the other case, happening by accident, seemed to have been the direct cause of death. A Liverpool surgeon, however, had tied the vertebral arteries in a number of cases for epilepsy, in some of which a cure seemed to have been effected; others were benefited. In none had evil resulted directly from the operation.

EXOSTOSIS OF THE ETHMOID BONE.

Dr. HERMAN KNAAPP presented the specimen, which had been removed from a woman, 45 years of age, who had suffered from nasal polypi for fifteen years past. Several operations had been performed at different times for removal of the polypi, and lately they had grown very rapidly. Some weeks ago, when the patient first consulted him, one nostril was nearly completely plugged, and the other also largely occupied by the growths. He advised their removal, which was done by Dr. Lincoln, the sittings extending over several weeks. He then said he could go no further. Dr. Knapp removed the tumor, which was pressing the eyeball towards the temple and forward. Its removal was easily accomplished, and in a very simple manner, judging from operations of a like kind done before. No reaction whatever was anticipated. A sharp spoon was employed to remove the remaining accessible polypi, a number of which existed in the frontal sinus. The patient did well for the first twenty-four hours, then began to complain of headache, cerebral symptoms increased, and she died in coma on the fourth day after the operation. At the

autopsy the dura on the right side of the convex surface of the brain was completely infiltrated with pus; the meshes of the pia, and the spaces beneath, were distended with serum, flattening the convolutions beneath. The pathological condition was much less marked on the left side, corresponding to that on which the operation had been performed, and also on the base. The ethmoid cells, and also those of the sphenoid, and of the frontal sinuses which could not be reached during life, were studded with polypi. There was cheesy pus in the sphenoid cavity, which doubtless had existed before the operation and had paved the way for death. The wound at the former seat of the tumor had healed by first intention, and no reaction had taken place. The tumor was found to have developed from the ethmoid, and was of ivory hardness. Dr. Knapp dwelt upon the necessity for removing nasal polypi before they shall have gone on to fill inaccessible cavities, to cause the collection and decomposition of the natural secretions, and have taken on a malignant character. He did not think the fatal result in the present case was at all due to the removal of the exostosis, although possibly this had something to do with lighting up the fire that already existed.

HYDATID MOLE.

Dr. CHARLES HEITZMANN presented a specimen of this nature, which had been expelled at the fifth month of pregnancy, and spoke of its microscopical appearances, saying that he agreed with the view of its true nature entertained by Virchow.

CANCER OF THE BREAST.

Dr. A. G. GERSTER presented the specimen, which had been removed from a woman who first appeared last spring at the German Dispensary. She had given birth to and nursed nine children. There was a slight bloody discharge from the nipple, but the gland was in no other respect affected. There was no sign of enlargement of the lymphatics in the axilla. He suspected cancer, but the patient would not submit to an operation, and the case was watched by his assistants until his return in the fall, at which time, they said, the condition was similar to that which had existed in the spring. On careful examination, however, Dr. Gerster found enlargement of the axillary glands, and removed them with the breast. This was the third case of the kind which he had seen in which the disease of the breast consisted only in a sanguineous discharge from the nipple, while the condition of the axillary glands pointed to undoubted malignant disease. He would call attention to the fact that unless a very careful examination were made, even in the lean patient, slight enlargement of the axillary lymphatics would be overlooked.

AMPUTATION AT THE THIGH FOR STRUMOUS AND PHLEGMONOUS INFLAMMATION OF THE KNEE-JOINT.

Dr. GERSTER also presented the leg which he had removed from a boy on account of the presence of a strumous and phlegmonous inflammation of the knee. Strumous disease of the knee-joint had existed for some time, but, fever developing, a physician was called, who regarded it as of rheumatic origin, and poulticed the knee, with the result of producing phlegmonous inflammation. The inflammation extended well up on the upper third of the thigh, and made it necessary to perform amputation. On account of a want of sufficient healthy tissue, a part of the flap was taken from the phlegmonous integument; nevertheless the patient made an excellent recovery, and the wound healed mostly by first intention. Dr. Gerster attributed this result to the use of a strong solution of bichloride of mercury, 1 to 500, which probably killed the germs of disease.

CANCER OF THE ŒSOPHAGUS.

Dr. H. K. HENSCHEL presented the specimen, which had been removed from a man 73 years of age, who had suffered for over two years with eructations and other dyspeptic symptoms, although not of a severe nature, until he became unable to swallow solids. Later, difficulty was experienced in swallowing liquids. There had been increasing dullness over the right side of the sternum at a point opposite that of the obstruction in the Œsophagus. The patient lost a great deal of flesh. After the passage of a bougie he spat up two clots of blood, and was then improved, gaining twenty-five pounds in flesh. But this was only temporary. A few days before death, symptoms of pleurisy developed at the point of dullness over the sternum, fluid exudation appeared in the entire chest, the patient became unconscious, and died. A large cancerous ulcer was found in the Œsophagus, which had ulcerated into the lung, and into which and the pleural cavity the contents of the stomach had entered by regurgitation and partially digested the tissues with which they came in contact.

AN ENORMOUS HEART.

Dr. B. ROBINSON presented the heart of a man six feet four or five inches tall and of large proportions, who recently died in the St. Luke's Hospital. He had suffered for several years with dyspnœa and other symptoms which might be attributable to disturbed circulation. Before death, on one occasion while dyspnœa was very great and the jugular veins distended, fifteen ounces of blood were withdrawn from a vein in the arm. Very great and immediate relief from the symptoms took place, but was not permanent. At the autopsy the heart was found to weigh

about fifty-five ounces, the largest of any which Dr. Robinson had found recorded.

THE PRESIDENT believed that the heart once presented to the Society by Dr. Clark weighed fifty seven ounces.

TYPHOID LESIONS OF THE INTESTINE.

Dr. ROBINSON also presented the intestines of a patient who died in the hospital in a relapse of typhoid fever. The temperature had run a very irregular course. Shortly before death it suddenly dropped to 96.6°. Two perforations of the intestines were found.

Dr. FERGUSON gave the history of a man in whom, at the autopsy, extensive lesions were found in the kidneys, congestion of the stomach and intestine, hypertrophy with dilatation of the heart, fibrinous adhesion between the visceral and parietal layers of the pericardium, and brown induration of the lungs. The man was about 25 years of age, single, addicted to the use of spirituous liquors, and had had rheumatism. His symptoms before death were dyspnoea, orthopnoea, headache, delirium, etc.

DISSECTING METRITIS.

Dr. H. J. GARRIGUES presented two specimens illustrating this affection, constituting the seventh and eighth of a series which had now come under his observation. The histories of the other six cases had been published. The first of the present cases was that of a woman who was confined with her third child at the Maternity Hospital last spring. Uterine and vaginal injections were employed. Some diphtheritic patches were noticed on the slightly-lacerated perineum. The head of the child had been delivered with the forceps. When the mass was discharged, which was about seven by two centimetres, the patient made a speedy recovery. The mass was composed of uterine muscular tissue. The second case was that of a primipara, and the delivery was normal. There was a slight laceration of the perineum. The uterus did not properly contract; the patient suffered pelvic pain. After some days, the treatment being by injections of carbolic acid solution, salicylate of soda, etc., a mass somewhat larger than in the other case, and folded upon itself, was discharged. It was found to be composed of uterine tissue. He had been able to find mention of but two similar cases, besides the ones he had published, and in those two cases the true nature was not recognized. A member of the Society stated, when he presented a former specimen, that certain cases had been reported in an Edinburgh journal; but this was a mistake, as neither Dr. Garrigues nor the gentleman himself had since been able to find such records.

MEASLES FOLLOWED BY CAPILLARY BRONCHITIS.

Dr. J. LEWIS SMITH presented the specimen, and made a few remarks upon the case,

and said that, as the hour was growing late, he would reserve the reading of the paper for another occasion. The child was five years of age, and had had measles, which progressed very favorably until laryngeal symptoms developed, and then, in spite of careful attention and treatment, it sank and died. The voice had been lost, but no pseudo-membrane could be found to account for it; there were the usual signs of capillary and general bronchitis. Dr. Smith remarked that when measles became complicated by capillary bronchitis the cases proved fully as fatal as did cases of scarlet fever.

The Society then went into executive session.

MEETING OF THE ALUMNI ASSOCIATION OF THE JEFFERSON MEDICAL COLLEGE ON THE DEATH OF DR. J. MARION SIMS.

REMARKS BY PROFESSOR S. D. GROSS.

A SPECIAL meeting of the Alumni Association of the Jefferson Medical College was held at the college on Friday evening, November 16, to take action upon the death of Dr. J. Marion Sims, of New York.

Prof. S. D. Gross, President of the Association, in opening the meeting made the following remarks:

Gentlemen of the Alumni Association,—The object of our meeting this evening is no ordinary one: it is to express our grief at the loss of a great and distinguished man, Dr. J. Marion Sims, one of the most eminent members of this Association, as well as one of the greatest ornaments of the school, and at the same time to express our sympathy with his bereaved family.

Dr. Sims occupied a prominent position before the profession of this and other countries for upwards of a quarter of a century. I have known him for a long time, and in his death I feel that I have lost one of the best and truest of friends. He was a man of wide reputation; and I venture to say that the youngest member of the class now attending Jefferson Medical College has heard of the name of J. Marion Sims. Every physician, however obscure, is familiar with his labors, his skill, and the benefits he rendered to the profession. It is to give expression to our feelings at the great loss we have sustained that we are assembled here this evening. Six years have elapsed since we met in this room to take action upon the death of Dr. Washington L. Atlee, a man whose name is distinguished as one of the founders of gynecology in this country; and only about a year and a half ago we gathered here to express our grief at the loss of another great man, one not a graduate of the school, but a member of the Faculty of the college, Prof. Joseph Pancoast, a man whom

we all loved, and whose memory lives after him. Now we meet to do honor to the memory of Dr. Sims.

Dr. James Marion Sims was a native of South Carolina, where he was born in 1813. His early education was received at Charleston, in the medical school of which he was graduated in 1832. He came to Jefferson College in 1834, and took his degree the following spring. He settled in Montgomery, Alabama, and soon after he met with a large number of cases of vesico-vaginal fistula, chiefly among colored women. As their condition at that time was generally considered hopeless, his sympathy was excited for them, and he set to work to devise some means for their relief. In consequence of representations made to him, he determined to establish a private hospital for the treatment of such affections. The hospital contained sixteen beds, and in it he performed a large number of operations, most of which were perfectly futile. But he persevered, and he was not satisfied until in 1848, when, having had his first success in the relief of vesico-vaginal fistula, he had achieved a great triumph. Operations of this kind had been practised before in different parts of the world, but these operations were not based upon any well-founded principles; and it was only after long study and perseverance that he was able to lay down the correct principles for the successful treatment of this distressing malady. There was an incident in his life that I must here refer to. A lady had the misfortune—or the good fortune, as it turned out for the interests of scientific progress—to fall from her carriage and dislocate her womb. In order to reduce it, Dr. Sims placed her upon her knees and elbows and restored the dislocated organ, and to his surprise he saw the vagina remaining widely distended. This was a revelation to him, which led him to adopt this posture in his future examinations and operations, which is universally known as Sims's position, and it also led to the invention of the Sims's speculum, in connection with which his name will always be known. The operation for vesico-vaginal fistula has now been performed thousands and thousands of times in all parts of the civilized world, all based upon the principles originally enunciated by Dr. Sims. I do not propose to speak longer of this operation of Sims or of his other contributions to surgery, but there are several points in his character that I will briefly refer to. Sims was a man of keen observation: he allowed nothing to escape his mind. Thousands of human beings had witnessed the fall of an apple, but it was not until it was noticed by a Newton that it led to the discovery of the laws of gravitation; and thousands had seen the swinging lamp in the cathedral at Pisa, but it never led to any result until it was observed by Galileo, who first appreciated its value for measuring

time and applied it as the pendulum-movement in the clock. So it was with Sims. He applied the information which he gained from that woman with the dislocated uterus with such genius and ability that he is known everywhere as the Father of American Gynæcology. He was a man, moreover, of great patience and tenacity of purpose. Upon one of his cases he performed the same operation thirty times,—an example of patience seldom paralleled in the annals of our profession. He was determined to succeed,—determined not to be foiled in his efforts to relieve the poor victims of a loathsome affection.

Dr. Sims was a gentleman, a gentleman of the highest type. He was a large-hearted man, a liberal-minded man, a man generous to a fault, and a man of brilliant intellect. He was never connected with a chair in any medical school,—his health never permitted him to assume the duties of such a position,—but he was a well read man and an author; he expressed himself with eloquence and in the best language. But, gentlemen, this man died poor. He died poor because he could not help it. From a private letter which I received from him, dated in Paris last May, I learned the reasons why he did not make America his permanent home, why he expatriated himself for the greater portion of the time. He says, "I can make as much money in New York as I desire, but the climate does not agree with me as well as that of Europe. I can make more money there with less labor, and the expenses of living are less. Besides, it is not necessary I should assist Harry any longer: he is fully able to take care of himself."

The history of Dr. Sims is known not only in this country but in every part of the earth. He performed his operations in every civilized country in Europe, and was everywhere received with honor. France, Italy, Spain, Belgium, and Portugal sent him their decorations, the highest gifts bestowed upon foreigners for merit. Dr. Sims was connected with a great many medical societies in this country and in Europe; everywhere he went he was honored. When he went abroad, in 1861, he was invited to perform his operations in many of the hospitals of London, Paris, Belgium, and Dublin, which were thrown open to him for the purpose of demonstrating his methods.

Gentlemen, this was the man whose memory we meet to-night to commemorate. I think it proper that a committee should be now appointed in order to draft suitable resolutions expressive of our deep regret at the loss we have sustained, and of our warmest sympathy with his bereaved family.

The chair will nominate Drs. Hewson, Pancoast, and Andrews for this duty.

The committee presented the following resolutions, which were offered by Dr. Addinell Hewson:

"Whereas we have learned with extreme surprise and regret of the sudden demise of our distinguished fellow-alumnus, Dr. J. Marion Sims, an event which occurred from heart-disease, in the city of New York, on the morning of the 13th instant, at a time of his life when he seemed as active and zealous in his work as ever ;

"And whereas we feel that his loss is a most grievous one, not only to his immediate family, but to all who had relations with him either socially or professionally in the many years of his brilliant career in this country and abroad, we would desire to give some expression here of our heart-felt sympathies with those to whom his memory must be ever dear,—of our appreciation of him as a refined gentleman, and of our pride in him not only as a fellow-member of our Association and one of the most distinguished of the alumni of our *alma mater*, but as one of the most learned, liberal, and skilful members of the profession of the present day : therefore be it

"Resolved, First, that we offer our kindest sympathies to his family in their great affliction, with our assurances that they must ever be proud of those relations which bound him to them and to us. Secondly, that we, as individuals, as well as a body, will ever feel our loss in his death, and remember with pride and satisfaction what he did to exalt our calling and to advance the purposes of our Association."

The resolutions were unanimously adopted, after remarks by Prof. William H. Pancoast, Prof. Parvin, and Dr. Hewson, and the meeting adjourned.

MISCELLANY.

A FRAGMENT OF THE CODE CONTROVERSY IN THE NEW YORK ACADEMY OF MEDICINE.

—The following has been received from Dr. Harwood, the author of the communication :

"The following reasons why one of the Fellows of the New York Academy of Medicine declined to vote on resolutions when the yeas and nays were called, are contained in a communication to the Academy at its meeting held October 18, 1883 :

"Mr. President and Fellows of the New York Academy of Medicine :

"Important as the business before the Academy is, the undersigned believes that in view of the serious misrepresentations made as to his position regarding the voting on Dr. Flint, Jr.'s resolution, April 19, 1883,* he will be permitted, as a matter of privilege, to make a brief explanation.

* Resolved, That the Academy hereby disavows any sympathy with the action of the State Medical Society, which has put the profession of the State, through its State and County Societies, in an attitude of opposition to the medical profession of the rest of the United States.

"When called on to vote on said resolution, he declined to do so, and was subsequently reproached, both within and without these halls, for duplicity, timidity, and similar unpleasant qualities. He desires to state that his declining to vote had an entirely different motive from any which could be based on the contents of said resolutions. He believed and stated at the time, and still believes, that *said resolutions were out of order*, or, at least, inconsistent with those passed about a year previous and which were offered by Dr. Austin Flint, Sr.

"To those who have forgotten the transaction alluded to it may prove of interest to know that according to the Secretary's minutes of April 6, 1882,† 'The report of delegates to the State Medical Society was then taken up, and after remarks by Dr. Austin Flint, Sr., he moved that the report be accepted and the further consideration of the topics and objects which it contained be indefinitely postponed.

"Seconded and unanimously carried.'

"He was therefore in the unpleasant alternative position of either voting against resolutions which the Academy had previously sustained the *spirit of*, or of voting for them and repudiating the previous resolution carried by the Society. Aside from this, the defect of the resolution, the one before the house was not voted for as required by Section 5, Article XXV. of the By-Laws, which requires that the yeas and nays on any question shall be taken without debate, and recorded in the minutes, when called for by five Fellows present. It is a fact that the yeas and nays were not called for by five Fellows in accordance

Whereas, The New York Academy of Medicine has adopted in its By-Laws as its standard of medical ethics the Code of Ethics of the American Medical Association, and

Whereas, Each newly-elected Fellow of the Academy is requested to sign its Constitution and By-Laws, be it

Resolved, That the Committee on Admissions be and is hereby instructed to report to the Academy for election as Resident Fellow no physician who is known to the Committee to be in opposition to the Code of Ethics of the Academy, and who, as a consequence, cannot consistently sign the By-Laws of the Academy.

Resolved, That these instructions to the Committee on Admissions be continued in force until the American Medical Association shall have modified or repealed its Code of Ethics and such modification or repeal shall have been adopted by the Academy, or until the Academy shall have modified or repealed its By-Laws referring to medical ethics.

Dr. Gouley moved that reconsideration of the vote on that resolution instructing the Committee on Admissions be indefinitely postponed. Seconded and carried.

It is claimed that the passage of these resolutions was secured through a packed house, brought about through the medium of a secret circular.

On motion of Dr. A. L. Loomis, duly seconded, these resolutions were rescinded by a large majority-vote, leaving the National Code intact and the qualifications for resident Fellowship as formerly required by the By-Laws.

† The report cited referred to the New York State Code, and, as it was not in accord with the Code of the Academy, it was thought best to bury it, which was done with the full assent of all the Fellows present ; but a year or more subsequent it was in effect unwisely and unlawfully resurrected, for what purpose cannot be appreciated, but its effect was to cause, what Dr. Flint, Sr.'s motion was intended to avert, bitter feelings and unpleasant commotion among the Fellows. It is now hoped, as the Academy is again restored to its original basis, that scientific work will be renewed, and peace and harmony will forever prevail within its walls.

with the provision of the By-Laws, and this fact can be ascertained from the minutes.

"Respectfully submitted by

"(Signed) ED. C. HARWOOD, M.D.

"44 WEST FORTY-NINTH STREET,
NEW YORK, October 18, 1883."

CANCER OF THE BREAST IN A GIRL.—A remarkable instance of the breast being attacked with cancer has lately occurred in a patient aged only 13 years, who was last week under the care of Sir George Porter, in the Meath Hospital, Dublin. The part implicated was removed on the 24th ult., and the case is interesting in consequence of the youth of the patient. The cancer was not scirrhus, but consisted of a soft variety of the disease. —*Lancet*, November 3.

FRACTURE OF THE THYROID CARTILAGE IN LEGAL MEDICINE.—Suspicion of murder led to the disinterment in San Francisco of the body of a man who recently had been found dead. Upon examination, fracture of the right wing of the thyroid cartilage was discovered, showing that the man had come to his death from strangulation, due to pressure with the right hand of an assailant.—*Pacific Medical Journal*, October.

TREATMENT OF TAPE-WORM BY MALE FERN.—Empty the bowels by a mild purgative on the day before the specific treatment. Give the oleoresin of male fern, mixed with two parts of castor oil, in capsules containing about forty-five grains, of which six or eight may be given. Administered in this way, Dr. E. Dieterich says that it does not derange the stomach.—*London Medical Record*.

THE *Drug News* states that Dr. Brandini, of Florence, has recently discovered that citric acid will assuage the violent pain which is the usual concomitant of cancer. He applies to the part pledgets of lint soaked in a solution of four grains of the acid in three hundred and fifty grains of common water, with the result of affording instantaneous relief.

GERMAN HOSPITAL AMBULANCE SERVICE.—A HANDSOME DONATION.—The German Hospital of this city has received a gift of one thousand dollars from the managers of the German-American Bi-Centennial Association, through Dr. Ferdinand H. Gross, President. This amount will be devoted to establishing an ambulance service.

APPOINTMENT OF SURGEON-GENERAL.—Surgeon Robert Murray has been appointed Surgeon-General U. S. A., as the successor of Surgeon-General Crane, recently deceased.

FORMAD ON BACILLUS TUBERCULOSIS.—At the last meeting of the Philadelphia County Medical Society, Dr. H. F. Formad gave the results of his recent investigations into the pathology of tuberculosis, which will appear in an early issue of the *Times*.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY FROM NOVEMBER 10 TO NOVEMBER 24, 1883.

MOORE, JOHN, LIEUTENANT-COLONEL.—Relieved from duty as Medical Director Department of the Columbia. G. O. 29, Department of the Columbia, November 8, 1883.

BACHE, DALLAS, MAJOR AND SURGEON.—Ordered to report in person to the commanding general Department of the East for assignment to duty. Paragraph 10, S. O. 259, A. G. O., November 12, 1883.

BACHE, DALLAS, MAJOR AND SURGEON.—Assigned to duty at Fort Adams, Rhode I-land. Paragraph 5, S. O. 215, Department of the East, November 19, 1883.

BROOKE, JAMES, MAJOR AND SURGEON.—Relieved from duty at Angel Island, California, and assigned to duty as post surgeon, Presidio of San Francisco, California. Paragraph 1, S. O. 162, Department of California, November 14, 1883.

HORTON, SAMUEL M., MAJOR AND SURGEON.—Leave of absence granted October 20, 1883, extended three months. Paragraph 7, S. O. 266, A. G. O., November 20, 1883.

TOWN, F. L., MAJOR AND SURGEON.—Until further orders, to perform the duties of Medical Director Department of the Columbia. G. O. 29, Department of the Columbia, November 8, 1883.

WILLIAMS, JOHN W., MAJOR AND SURGEON.—Granted leave of absence for one month, on surgeon's certificate of disability, with permission to leave the limits of the Department. Paragraph 5, S. O. 157, Department of the Columbia, November 12, 1883.

APPEL, D. M., CAPTAIN AND ASSISTANT-SURGEON.—Granted two months' leave of absence. S. O. 68, Division of the Atlantic, November 16, 1883.

GARDINER, J. DE B. W., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty at Fort Huachuca, and assigned to duty as Post Surgeon at Fort Bowie, A. T. Paragraph 1, S. O. 104, Department of Arizona, November 8, 1883.

MUNN, CURTIS E., CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty at Fort Warren, Massachusetts. Paragraph 4, S. O. 216, Department of the East, November 20, 1883.

WINNE, CHARLES K., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty at Fort Winfield Scott, California, and assigned to duty as post surgeon, Angel Island, California. Paragraph 1, S. O. 162, Department of California, November 14, 1883.

APPEL, A. H., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Relieved from duty at Fort Warren, Massachusetts, and assigned to duty at Madison Barracks, New York. Paragraph 4, S. O. 217, Department of the East, November 21, 1883.

COCHRAN, J. J., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to duty at Fort Bayard, New Mexico. Paragraph 5, S. O. 236, Department of the Missouri, November 15, 1883.

ORIGINAL LECTURES.

REMARKS UPON CLINICAL CASES.

A Lecture delivered December 1, 1883, at the Pennsylvania Hospital,

BY PROF. J. M. DA COSTA, M.D.,

One of the Attending Physicians to the Hospital, etc.

[Reported for the MEDICAL TIMES.]

DIPHTHERITIC PARALYSIS, WITH REMARKS UPON ITS DIAGNOSIS FROM LEAD-POISONING.

GENTLEMEN,—The first case to which I will call your attention this morning is that of William S., 21 years of age, a laborer. He was admitted into the ward on the 26th of November. As regards his occupation, he states that he has worked a good deal in lead-works, and about April 1 of this year he was particularly engaged in working in a manufactory in this city, grinding, mixing, and packing white lead. He does not, however, seem to have suffered from any ill effects from the lead; in so far, at least, as there has been no history whatever of attacks of constipation, colic, or loss of muscular power. In August of this year, he had an attack of diphtheria, lasting for two weeks; he then returned to his work feeling as well as he ever did in his life. After working for a week, however, he found himself getting very fatigued at night. He had pains all through his body, and the limbs also, at that time. It seems, therefore, to have been a subsequent phenomenon to the severe sore throat. His symptoms getting worse, he gave up his work at the end of two weeks, to remain at home, though not in bed. Now, at this period there was marked difficulty in swallowing, and he found that liquids returned through his nose when he attempted to drink.

Upon admission to the hospital, what he most complained of was general tenderness and want of power in his limbs. His throat-symptoms were better; he could swallow without difficulty. We could detect no blue line upon his gums; but what was particularly noticeable, and what particularly brought him here for treatment, was that he could scarcely stand upon his feet, and was not able to walk at all. We found that this loss of power was not confined to the lower extremities, though it was there more marked; there was also loss of power in his arms; he had a weak grasp, and things would drop out of his hands. The

right hand showed rather more loss of power than the left. He has had no evidence of facial palsy; he was not constipated; his tongue was moist and slightly coated, and marked by the teeth. The lungs were normal. The first sound of the heart was weak, and there was a faint blowing systolic murmur; the second sound was distinct. The liver and spleen were normal in size.

He has only been in the hospital since the 26th of November, but in these few days he has been decidedly improving; though what brought him here, the loss of power, in the legs especially, is still a very prominent symptom. We will test the matter for ourselves. I have told you that he could not walk: now he can do so, but with great difficulty and the assistance of a cane; he stands without assistance. As he lies in bed, with his back supported, he has considerable power over the legs; you see that the loss of power is not complete; it is in walking that the loss of power is most marked. There does not seem to be any impairment of common sensibility to the touch, and tested with the æsthesiometer. Testing the tendon reflex, we find that the patellar tendon reflex is absent: this you may say of both legs. When I tickle the soles of his feet he feels it distinctly, but there is no reflex muscular action. He feels the prick of the pins and the compass-points. This is in the legs. We will proceed to test them with the battery. The muscular fibres of the gastrocnemius of the left leg, even with a strong faradic current, exhibit no contractions; a current of greater strength produces faint contractions. In the same way, with this very strong current acting upon the muscles of the anterior part of the leg, we obtain very slight contractions. The current, indeed, is so strong that the pain—for he feels this distinctly—produces reflex contractions of the muscles of the upper part in the thighs; the same result being obtained upon the right side as upon the left.

Therefore, we have greatly diminished, almost abolished, electro-muscular contractility, while the sensibility is fairly well preserved. In the thigh, both in the muscles of the front and the back, the electro-muscular contractility is better preserved, though even here, as compared with the normal, it is diminished, and the sen-

sibility is greater here, for with this same current the muscular sensibility is more evident in the thighs than in the legs; but on the whole, considering the strength of the current, I should say that it is actually, though slightly, diminished. Testing the fingers of the right hand with the æsthesiometer, while he feels the two sharp points he cannot tell them apart very readily: therefore there is some defective sensibility in the fingers of this hand; two points, half an inch apart, are only felt as one. In the left hand the same condition is found to exist.

In the muscles of the arms and forearms both, but more especially the forearms, we have the same electric reactions that we had in the muscles of the legs; that is, very much diminished electro-muscular contractility; and electro-muscular sensibility is also very much impaired. Even with this strong current you see that there is very little response. The flexors act better than the extensors, both in arm and forearm; he feels the current more decidedly than in the legs, but I should make the same observation here as before: the electro-muscular sensibility is reduced considering the strength of the current, for he does not feel the same pain that anybody else would. In the biceps and triceps the same inaction is observed. So, in the main, it comes to the same as in the legs. Observe, also, that the skin is rather bluish, both on the arms and legs; this is due to defective capillary circulation. I will repeat the observation made upon admission: there is no blue line upon the gums.

What is the matter with this man? Here is a double history,—a history of exposure to white lead, and a history of sore throat, which may have been diphtheria. You see at once that there is paralysis, and that it is general, both in the legs and arms. Is this palsy due to his occupation? or did it follow the sore throat which he called diphtheria? This is the problem that confronts us, and it is not as easy of solution as you might at first have thought. You may think that we will be able to get some assistance from the electric reactions that I have shown you, but the differences between the electric reaction of diphtheritic palsy and that of lead-poisoning are those of degree rather than of kind. In both there is greatly diminished electro-muscular contractility. It is true that in lead-poisoning this amounts to absolute

loss of power to contract even under the strongest electric currents, whereas in diphtheria this electro-muscular contractility is generally diminished rather than lost. Therefore, so far as this examination goes, the character of the paralysis is more in favor of diphtheria than of lead-poisoning, because we found that the muscular power, though diminished, was not entirely lost. And there are strong reasons for this view, and I announce it as my opinion, that the occurrence of the lead is a mere accident, and that all this paralysis is really due to diphtheria. I will give you my reasons for this view of the case.

In the first place, the *general* character of the palsy is in favor of diphtheria. It is in the arms as well as in the legs; in the flexors as well as in the extensors. In the palsy that exists from lead, this, as the rule, is not the case. I know there are exceptions, but, for the most part, the palsy from lead is local and limited to groups of muscles, especially the extensors. Therefore the extent of the paralysis is against lead and in favor of diphtheria.

Further, there has been here what is, I think, of considerable value in the history of the case: associated with the symptoms of loss of power in the extremities (which have now reached the point that he is unable to walk, except in a very limited way with assistance), there has been throat-palsy. The loss of power in the extremities was *preceded by signs of throat-paralysis*,—difficulty in swallowing, liquids regurgitating through the nose, etc.

Thus, in looking over the history of the paralysis, we find it to be that of diphtheria rather than of lead. You see I have been dwelling upon points of the paralysis itself and the way in which it originated, rather than upon the negative evidence of the absence of the blue line upon the gum and the absence of colic and constipation; for, after all, we might be deceived, and might lay too great stress upon their non-existence.

As regards the blue line upon the gum, it cannot always be detected in lead-poisoning; especially in cases like this might we be mistaken, where there is an accumulation of tartar on the teeth. Therefore do not dwell too much upon signs that are merely negative of lead in the system.

Now, when you come to examine further into this case you see evidence of a decided deterioration of the blood, which is

common in diphtheria,—that is, a soft murmur in the heart, due to blood-changes,—an anæmic murmur; the first sound of the heart is weak; the circulation generally is feeble. You have already noticed the defective capillary circulation.

You have had developed before you the diagnosis of this case of diphtheritic paralysis, which I have taken the opportunity of comparing with lead-poisoning, which also might have existed here from the peculiar history which we have obtained. The chief points upon which I base my diagnosis of diphtheria are, as you see, the general character of the muscular palsy (the loss of power being partial, not absolute); the existence of a certain amount of electro-muscular contractility; the history of antecedent sore throat, followed by difficulty in swallowing, and the rapid improvement in the paralysis (that of the throat having completely disappeared); and, on the other hand, the evidence of anæmia, defective heart-power, and enfeebled circulation, which are common to diphtheria.

Let us now ask ourselves what are the chances for his recovery, and what treatment will best bring about this recovery. The chances for his recovery are excellent. With the good care that he will receive here, the nourishing food and constant attention, I have no hesitation in saying that he will leave this hospital well. In truth, diphtheritic paralysis is one of those diseases where treatment can do a great deal.

Now, as regards the treatment of this case, I would say this: it must consist, first, in improving the quality of the blood. This is of course, and it is to be accomplished by iron,—the tincture of the chloride of iron, for instance. There is no better remedy than this, and you may give tincture of the chloride of iron in twenty-drop doses three times a day, which will be sufficient as a tonic dose. Then the remedy for cases of this kind, undoubtedly, in addition to the iron and plenty of animal food to improve the condition of the blood, is strychnia. The best means of using it is hypodermically; but there is a certain amount of inconvenience in administering it in this way. It is easier to give it by the mouth; but if I think that he is not improving as rapidly as he should, I will at once order it. He shall take it first in the usual way. We will give him the following:

R Strychninæ, gr. $\frac{1}{30}$,

in pill, thrice daily. He has been taking the fiftieth for several days, and it may now be increased. He shall also continue the tincture of the chloride of iron (gtt. xx t. i. d.) and a full nourishing diet.

The only question remaining to be considered in this interesting case is, Shall we make use of the battery as a part of the treatment? Hitherto it has been used only for diagnosis. What form of battery should be used? I will say this: there is no doubt that the muscular nutrition will be best kept up here by the judicious use of the battery to stimulate the various muscles. Where you find in these cases that the faradic battery produces contractions, use the induced current; where it will not, use the primary or galvanic current. Here the faradic current produces contractions, and we will adhere to it, applying it in turn to the different groups of affected muscles every other day.

This shall be the treatment, and, unless I am greatly mistaken, the man, in the course of a very few weeks, will present himself before you and walk into the clinic-room without a trace of his paralysis.

ACUTE PHTHISIS PULMONALIS.

James McB., 23 years of age, was admitted into this hospital November 21. His father died of pleuro-pneumonia after six months' illness. Remember, this is his own statement. His father died with progressive pulmonary disease, that is evident; but it is not likely that it really was pleuro-pneumonia, although he tells us so. It was a chronic lung-affection, probably phthisis, though it might have been one of those forms of inflammatory conditions of the lung which sometimes are continued for months. He says that his mother is living and well. One brother died with smallpox, two brothers and sisters are living and healthy.

Therefore, with the single exception of the father, who had what might have been pneumonic phthisis, or it might have been chronic inflammatory disease of the lung, there is no history of hereditary lung-trouble. Investigating his personal history, we learn that he is single, and is a tailor. He worked at his trade in 1876, and for some time after; he then tended bar for a while, then went on a farm for two years, and after that worked irregularly at his trade. He says that he has not been a drinking man.

About two years ago, he tells us, he was wrestling with a large man, and he was attacked by spitting of blood; and although the hemorrhage was quite free and he spat up a great deal of blood that afternoon according to his account, he did not seem to have any ill effects, for he went to his work as usual the next morning. I ask him if this is so, but I find that he is very deaf, and I fear that we will not be able to get much from him directly. I recall the fact that the history we have was only obtained with great difficulty, but we think that it is perfectly correct. I will adhere, therefore, strictly to the written statement, and give up any further attempt to get information from him.

He stated positively, and adhered to the statement, that he had no cough at all before the 3d of November, when he caught a severe cold. Since that time he has had cough, free expectoration mixed with blood, fever, night-sweats, prostration, and rapid loss of flesh. He has also complete loss of appetite, and constipation. The urinary examination was negative.

He has now not a great deal of cough, and a muco-purulent expectoration tinged with blood. He has had no free hemorrhage since the time he was wrestling that I have just mentioned, and, except an occasional mouthful of blood mixed with mucus, he has had none since he has been in the hospital.

You see by this record of the temperature, which is decidedly a temperature of fever, the character and progress of the disease since admission. It was 102° on the evening he came in, it has several times been down to 101° , and again here it goes up to $103\frac{1}{2}^{\circ}$, never down to normal, but usually showing a morning remission of one or two degrees. There are sweatings at night, and his cough is worse at night. The expectoration is not very profuse.

Now, gentlemen, he is emaciating rapidly, I am sorry to say: notwithstanding the strong efforts we have made, he has even fallen away considerably since he has been in the hospital; there is progressive emaciation.

Upon examining his chest, I find, by percussion, dullness over the whole right side; over here, on the left side, I do not find any dullness, except just under the clavicle, where it does not strike me as being perfectly clear. Everywhere on the right side

there is dullness, except at the apex in front, where the note sounds tympanitic. On auscultation, I find under the right clavicle, most distinctly, loud crackling sounds; they mask the breath-sounds, but on expiration I occasionally catch the respiratory sound, which is hollow and blowing. Lower down in the lung the sounds that are emitted are coarse, crackling, with a good deal of hoarse, harsh, almost bronchial breathing; that is, anteriorly. Posteriorly, I find also coarse, crackling râles at the apex, but not the hollow respiration which I perceived anteriorly; coarse râles, with here and there finer crackling and harsh, vesiculo-bronchial and in parts almost purely bronchial breathing, may be said to exist over the whole right lung posteriorly. Now let us see what the left lung will teach us. There is exaggerated breathing, which, at the lower part of the lung, may be said to be harsh respiration, perceptible everywhere. There are very few, if any, distinct râles anywhere, except that just about the middle of the lung I find a few, but none very distinct; and the only thing that strikes me at all—barring this harshness of murmur, which is most evident at the lower part of the lung—is a slight prolongation of the expiration which I notice at the apex.

Now, what is the matter with this man? I should not ordinarily discuss a case of this kind in the presence of the patient, but, as he cannot hear me, it will do no harm. He tells us that he has only been ill apparently since November 3, and we are now only at the end of the month. The question which arises is, "Has he or has he not tuberculosis?" Is it a case of phthisis, or one of ordinary inflammation of the lung? Gentlemen, I think it is phthisis. It is true it is confined to one side, but on no other view can I explain the rapid breaking down of the lung; while the night-sweats, and the rapid emaciation, also suggest this explanation of the case. Although he told us that he caught cold at the beginning, we know nothing of it: it may have been simply the commencement of those severe symptoms.

I am sorry to make the diagnosis—you know what it means to him—of acute phthisis; to say that the right lung is being destroyed, and that no treatment will be able to permanently stay the progress of the disease to its fatal termination.

The left lung, very probably, will also soon become implicated. This is the diagnosis and prognosis.

Let me point out a few points of clinical interest in this unfortunate case, where there is great and rapidly-progressing emaciation, fever, exhausting night-sweats, and marked destruction of the lung, coming on in the course of less than a month.

While there are those who believe that acute pneumonic phthisis and tuberculosis are distinct pathological processes, who hold the view that one originates in inflammation, the products of which become degenerated, and the lung converted into a caseous mass which subsequently breaks down, and yet there is no true tubercle, I must say this is a doctrine that I never did believe in, and I find myself believing in it less and less, the more I study such cases. I merely mention this as a matter of pathological interest, as this might be called by some a case of acute phthisis of inflammatory origin. I pronounce it a case of acute tuberculosis of the lung, for reasons which I cannot go into now, as it would lead into a discussion which would be more pathological than clinical.

The irregular fever, the cough, the night-sweats, the hemorrhage, and signs of softening make this case but too clear as being now one of acute phthisis, whether you look upon it as being inflammatory in its outset or tubercular from the first.

There is one point that should be mentioned: what about the original hemorrhage? Ought that to be considered as the cause of the subsequent events? I ought not to discard this from the history. Hemorrhage from the lungs may be followed by phthisis. I have seen persons apparently in perfect health, and in whom by no means of investigation could you have been able to detect any departure from health, who, as the result of a strain, have had an attack of congestion of the lungs and hemorrhage, which finally led to the development of phthisis. I merely point out that this has happened. I shall not detain you with a long account of how it happens. I simply state to you that if such an accident does occur, a part of the blood may be left behind to act as an irritant; and if the patient is at all disposed to tubercle, phthisis may afterwards develop as the result.

What can be done for this man? You think, probably, that I am entering into the question of treatment in a very hopeless frame of mind. This is true; but we must do the best we can for this poor man. There are cases in which the tubercular disease is stayed for a time, remains stationary, and life is thus prolonged. We will therefore do what we can to check the activity of the disease. We shall give him at night the one-hundredth of a grain of atropia to check the night-sweats. He shall have easily-assimilated food at short intervals, on account of his weakness; stimulants will be ordered, though in moderate quantities,—three ounces of whiskey a day, given in punch. We shall endeavor to keep down the irritative fever by a combination which is commonly used in these cases. It is a modification of Niemeyer's pill:

R Pulv. digitalis, gr. $\frac{1}{2}$;
Pulv. opii, gr. $\frac{1}{4}$;
Quininæ sulph., gr. i.

M. Ft. pilula.

Of this he has been taking one every three hours. He has been more comfortable since he has been taking this combination, and we will continue it. It is not a case for cod-liver oil, and not a case for nutrients,—I mean by that the iodide of iron and articles which change nutrition,—unless the man should happen to get rid of the fever and we have to do with a chronic case rather than an acute one. In its present condition the case is decidedly acute, and will be best treated by the measures we have indicated.

Gentlemen, I had other cases to bring before you; but, the hour having expired, I must reserve them for our next meeting.

THE INCURABILITY OF CONGENITAL COLOR-BLINDNESS.—Dr. B. Joy Jeffries calls attention to the fact that it is almost universally conceded by ophthalmologists and experts that congenital color-blindness is incurable. He refers to the contrary view held by Favre, of Lyons, France. Dr. Jeffries agrees in urging the value of educating the color-sense among the children of public schools.—*Medical Record*.

RESORCIN IN ANTHRAX.—In the treatment of carbuncle the following combination has been used with great satisfaction:

R Resorcin, $\mathfrak{z}\text{v}$;
Vaselin, $\mathfrak{z}\text{ij}$. M.

S. Apply.

ORIGINAL COMMUNICATIONS.

REPORT ON PROGRESS IN HYGIENE, TOXICOLOGY, AND MEDICAL JURISPRUDENCE.

BY HENRY LEFFMANN, M.D.

DANGER IN CANNED FRUITS.

THE extended use of articles preserved in tins makes the question of contamination by poisonous metals an important one. In some of the reported cases lead has been identified as the offending substance, but in my experience, notably with canned peaches, *tin* has been the metal dissolved. It appears by a report recently made by A. Winter Blyth, Medical Officer of Health to Marylebone, London, that of twenty-one samples of preserved fruits—apricots, tomatoes, and pine-apples—every one contained a dangerous quantity of tin, the least quantity found amounting to one and a half grain per pound, the largest to eleven grains per pound. The solution of the tin was, of course, due to the acid juices of the fruits. This solution, it may be observed, takes considerable time, and in the cases in which contamination has been found by me the fruits were more than a year old. Chemical tests were made on these samples, because they had caused some irritation of the stomach in persons who had partaken of them.

GENUINE WINES.

Those clinicians who are fond of extolling the merits of natural wines, and regard the artificial forms or simpler substitutes as not meeting indications, will be surprised to learn that, according to recent examination, natural wines are generally contaminated with substances of decidedly toxic qualities, as compared with ethylic alcohol. Some of these bodies—*i.e.*, amyl alcohol—are dangerous. The great regard which physicians generally have for the products of “nature’s laboratory” is not always based on facts.

THE USE OF ANTISEPTICS AND GERMICIDES IN ARTICLES OF FOOD.

The discovery of the specific preservative power exerted by such bodies as boric and salicylic acids has given rise to frequent use of them in various articles of food, and this fact renders important any inquiry as to the effect on the animal system of long-

continued use of these preservatives. A report has recently been published in Paris, which gives decided opinions on the question of the use of salicylic acid. It appears that some three years ago a Commission had, after investigation, decided positively against allowing this article to be used. The reasons given were that it has toxic properties, that the maximum safe amount is not known, and that, even if it were, the processes for estimating the acid in complex mixtures are not accurate enough to permit chemists to keep control over the articles sold. The Commission recommended the prohibition of the use of the acid, which was done. Much opposition, of course, arose from those who were engaged in selling articles thus preserved, and lately the question was reopened. It was pointed out, among other things, that new processes permitting of accurate determination have been discovered. The second Commission, however, after hearing all the arguments, refused to modify the original views. It still held to the views that the maximum quantity which could be taken was unknown, and that in many cases of disease, especially in affections of the liver and kidney, affections which are rather frequent, a contra-indication to salicylic acid exists. The prohibition against the use of this preservative is therefore continued.

The conclusions of the Paris Commission have an interest to us, because quite a number of preservatives and preserved articles are now in the market; the *rex magnus* which is being so extensively advertised is principally boric acid, but salicylic acid is also used, especially by brewers and bottlers.

The medical properties of boric acid and of its recent derivative boro-glyceride are little known, but the liberal use of these substances as antiseptics is likely to be for some time popular, and their effect when taken continuously in small doses is a matter of hygienic moment.

POISONOUS FOOD.

Many cases are recorded in which dangerous and even fatal symptoms have been produced by articles of food in which subsequent analysis has failed to establish the presence of any known poison. Comparison of different cases has not led to any very satisfactory result, for although it was evident that the food had in some way

suffered change, yet neither decomposition nor original disease appeared to be sufficient to render the substances poisonous. Many instances are noted in which putrefying flesh or flesh from diseased animals has been eaten without bad effects. The researches made in the last year or so on the products of putrefaction have given to us a clue, or at least the hope of one. The cadaveric alkaloids or ptomaines may very plausibly be regarded as the cause of poisonous effects. Some recent researches of Dr. L. Brieger, of Berlin, have an interesting relation to the question. In recording the recognition and isolation of new ptomaines, he points out that these products were only obtained in the earlier stages of the decay; as the process advanced the alkaloids were themselves destroyed. If this feature should be found to belong to all the ptomaines, we may certainly more easily understand the marked poisonous character of substances like sausage and cheese when in a state of staleness only, while similar articles are often eaten without effect when in even a marked condition of decomposition. Some years ago several deaths occurred in Philadelphia from eating old sausages. Specimens of the sausages were carefully tested, but no known poison could be found. They were not in a condition of active decay, but only markedly stale. It is not improbable that with the recently-acquired information on this subject a more satisfactory analysis could now be made.

ARSENIC IN KINDERGARTEN PAPERS AND TEXTILE FABRICS.

This subject has lately received some attention in medical journals. It appears that quite a large proportion of the papers sold contain arsenical colors, although non-arsenical papers are also furnished. Green colors are, of course, suspected at once; but reds have also been shown to be largely contaminated. Blue and yellow colors are mostly made with ultramarine and chrome-yellow, substances that cannot be considered as actively poisonous. The glazed papers are the most objectionable, for in these the colors are easily detached by the moist hands. The grade of papers known as "engine-colored," in which the coloring-matter is mixed in the pulp, is far more safe, because the material cannot be dislodged by water. A few weeks ago I made examinations of several samples of green paper of various shades

without finding arsenic. It is true, however, that these greens—which are possibly made of mixtures of chrome yellow and Prussian blue—are not so handsome as the arsenic-greens, while they are more expensive. The temptation, therefore, to use the more dangerous colors is very strong.

The supposed injurious effects of arsenical dyes are often referred to. Not only do the much-used aniline colors generally contain some arsenic as a residue from the arsenic acid used in the manufacture, but many of the chemicals used in the dye-house, such as sulphuric acid and tin chloride, are liable to arsenical impurity. As far as regards the arsenic in the dyes themselves, my examinations indicate that most of it remains in the dye-vat, since aniline reds which gave distinct reactions with Reinsch's test failed to communicate to yarn dyed by them any definite arsenical reaction.

POISONOUS HAIR-DYE.

No greater humbugs are palmed off on the community than quack medicines, and it is fortunate that many of them are frauds merely. Some of them are, however, decidedly dangerous, and among this class we find forms of hair-dye. An analysis of Ayer's Hair-Vigor, recently made in the laboratory of the Philadelphia Polyclinic, shows that it contains about a hundred grains of sulphur, and considerable sugar of lead. The sale of such a preparation under the deceiving title of a "hair-vigor" is a matter of moment in public hygiene. Cases of lead-paralysis from the local application of such dyes have been recorded, and the sale of these preparations ought to be prohibited by law. We have a poison-law in this State, which sets bounds on legitimate business; but the sale of any powerful poison is unrestricted if the name given to it is chosen to deceive.

ON THE ADVANTAGE OF AN ACQUAINTANCE WITH BOTANY AS A PRELIMINARY TO THE STUDY OF MEDICINE.

Read before the American Academy of Medicine, October 9, 1883,

BY BENJAMIN LEE, A.M., M.D., PH.D.,
UNIV. PENN.

Published with the approval of the Academy.

IN a paper which I had the honor to read before the Academy at its last meeting, and which was listened to with

much kind indulgence, I pointed, with what I considered to be a justifiable pride, to the noble record left by the founders of American medicine, and more especially by those who took the initial steps in the establishment of the first great centre of medical education in America,—the University of Pennsylvania. I was enabled to show that they were uniformly men of high culture and classical attainment, and that in the examinations which they instituted, the curriculum which they established, and the elevated and polished tone of their instructions, they aimed at perpetuating a line of physicians not less learned and accomplished than themselves. Not less clearly was I able to demonstrate the fact that this high standard of general attainment and elevation of character won for the profession of that day a social and political status commensurate with its true dignity, and truly enviable.

My task to-day is not of so pleasing a nature. I have to lament a fane neglected, a profession degenerate, an ancestry dishonored.

The retrospect of the succeeding epoch is by no means so flattering to the self-esteem of the patriotic student of American medical history. The age was possessed with the deceitful demon of an intense utilitarianism. It could see no good in anything which was not capable of being immediately and palpably converted into dollars and cents. All that could possibly be charged with the crime of being ornamental, of contributing to the adornment of life and of character, it scoffed at and frowned down. Medicine was compelled to share in the general debasement at the throne of Mammon. The style of education which it demanded was calculated to produce, and, with a few brilliant and praiseworthy exceptions, did produce, not physicians—men acquainted with the wide range of the physical sciences; not doctors—men learned themselves, and capable of teaching their fellow-men the great truths of physical life, of their relations to the world around them and to the forces of nature, and so induce them to lead healthier, happier, and more noble lives; but simply exhibitors of drugs, prescribers of pills and potions,—in the expressive language of the barbarians of our native wilds, “medicine-men.”

The call was for cheap doctors; and the supply was equal to the demand. All

over the country petty advertising agencies sprang up under the name of medical colleges, each new one offering its diploma at a less expenditure of time and for a lower standard of requirement than those already in the field. In order to keep their lecture-rooms full, the older colleges were compelled, or thought they were compelled, to accept students correspondingly less well prepared to enter upon the study of medicine, and to shorten rather than lengthen their terms of study, so that no opportunity was offered for supplementing this lack of qualification before graduation. The classics were soon kicked overboard. The Latin thesis, at first the rule, soon became the exception, and before many years was simply a curiosity of medical literature. The higher mathematics quickly followed, and finally the accessory sciences of botany, geology, comparative anatomy, and so on. Botany, however, held its own longer than any other of the supplemental departments of learning. In glancing over the interesting annals of the University of Pennsylvania, and its progenitor the Philadelphia Medical College, indeed, the attention bestowed upon this study from the earliest days of the College until comparatively recent times cannot fail to attract notice.

Three years after its foundation, in January, 1768, Dr. Adam Kuhn, returning from the completion of his medical education in Europe, where he had studied *materia medica* and botany under Linnæus himself, and the other branches at Edinburgh, received the appointment of professor of these two cognate subjects, which had heretofore been lectured upon by Dr. Morgan, as a part of his course on *Theory and Practice*.* This professorship he held for twenty-one years; but on the organization of the University of the State of Pennsylvania, in 1782, the two departments were separated, and the chair of Botany, after having been declined by Dr. James Tilton, of Delaware, was given to Mr. William Bartram. In 1789, when, through the exertions of Benjamin Frank-

* A letter of the great Swedish botanist is preserved, in which he thus congratulates Dr. Kuhn on this appointment:

“Viro Clarissimo Dno. Adam Kuhnio, in Philadelphia Botanices Professori, S. pl. d.

“Car. A. Linné.

“Tuas V. A. d. 12. Januarii datas hodie accepi et summo gaudio percepi, te professorem Botanices et *Materiæ Medicæ* in *Atheneo Philadelphico* constitutum; de quo, ex intimo corde gratulor! Hoc dixi uxori et literis, qui omnes, de tuâ hâc fortunâ, summum mecum percipere gaudium.”

lin and others, the College was again put in possession of its lost rights, Prof. Kuhn was reinstated, and continued to hold the position until the autumn of the same year, when he resigned it to accept the professorship of Practice of Medicine in the new university, and Dr. Benjamin Smith Barton, a native of Lancaster, in the State of Pennsylvania, was elected Professor of Natural History and Botany. This chair he filled most acceptably, not only delivering full courses of lectures for twenty-four years, and inspiring the students with a love of this science, which in several instances bore conspicuous fruits, but also publishing important contributions to its literature.* He resigned it only to take that of *Materia Medica* in 1796. Up to the year 1792, when the "University of Pennsylvania" assumed its present title and organization, attendance on the botanical lectures was compulsory. Dr. Barton, it may be said in passing, has been styled "the first teacher of natural science in this cis-Atlantic world."

Among those whom he trained as investigators in the rich field of the medical flora of the New World, and to whose efforts the whole world of medical science has tendered its acknowledgments for their valuable contributions to the *materia medica*, may be mentioned the honored names of Dr. William P. C. Barton, his nephew, Dr. William Darlington, Dr. William Baldwin, and Dr. Thomas Horsfield. In 1816 the chair of Botany ceased to appear on the list of regular professorships, from the fact that the trustees, in the vain hope of supplementing the purely technical courses by others designed to inform the students on allied branches of great importance to truly scientific men, established a "Faculty of Natural Science." This was the progenitor and model of the present "Auxiliary Faculty of Medicine," founded by the bequest of the late Prof. Wood, which is now doing a good but sadly-limited work among the post-graduates of the university and of other schools. First on the list of its professor-

ships was that of Botany; and Dr. W. P. C. Barton was at once called to assume its duties. Under his auspices renewed interest was aroused in the subject, and the trustees went so far as, with the aid of a liberal grant from the Legislature, to purchase a large tract of ground near the city, for the purpose of "establishing a garden for the improvement of the science of botany." This project, however, never seems to have been carried to its fulfilment. Among this gentleman's more important contributions to our knowledge of the therapeutic treasures in our fields and forests are his "Vegetable *Materia Medica* of the United States," "A Flora of North America," and "A Flora of Philadelphia."

The first mentioned of these works was a truly superb contribution,† in two large quartos, with finely-colored illustrations, and was "the first work of its kind ever published in America." Many of the plates were colored by the author's own hand.

In the course of the Preliminary Observations to the second volume the author complains feelingly of the growing influence of the spirit of which I have spoken in the opening of this paper. He says, "There are many discouraging circumstances connected with investigations of this nature, which I may not feel willing to combat or oppose. Among them is the notorious discouraging influence, at least in this city, relative to botanical pursuits, proceeding, too, from sources where accidental and professional elevation gives a kind of adventitious importance to opinions which would otherwise be wholly inefficient in their operation, if not beneath notice or refutation. As regards my own efforts, I am free to confess that my interests are too deeply connected with such opposition to the pursuits of the professorship I have the honor to hold, to be very solicitous to run counter to or struggle against such appalling circumstances. And at least necessity, if not the will, would urge a relinquishment of pursuits which are industriously taught to be incompatible with the severe and more useful occupations of medicine, or with the attainment of the more conspicuous eminence to which the practice of physic and surgery lead."

* "Collections for an Essay towards a *Materia Medica* of the United States. A paper read before the Philadelphia Medical Society by Benjamin Smith Barton, M.D., Professor of *Materia Medica*, Natural History, and Botany in the University of Pennsylvania, on the 21st of February, 1798." This little tract went through three editions, and introduced to the profession for the first time several remedies which have since become valuable stand-bys in practice. In 1803 he published his "Elements of Botany, or Outlines of the Natural History of Vegetables," illustrated by thirty plates, nearly all of which were original.

† *Vegetable Materia Medica* of the United States, or Medical Botany, etc. By William P. C. Barton, Surgeon in the Navy of the United States, etc., Professor of Botany in the University of Pennsylvania. Philadelphia, 1817.

In this work Prof. Barton introduces us to Dr. Schoepf, of Erlangen, Germany, a botanist who came to this country with the German troops during the Revolutionary War and employed himself in collecting materials for an American *materia medica*. In 1787 he published the result of his labors, in a small work entitled "*Materia Medica Americana Potissimum Regni Vegetabilis*," which Barton tells us, in his preface, laid the foundation of all the information we now possess concerning our native medicinal plants. Schoepf was certainly a most industrious collector as well as careful observer, the little vellum-bound copy of his book which I have had the good fortune to find in the library of the Pennsylvania Hospital containing three hundred and fifty-three distinct species, with their botanical characteristics, and, where known, their medicinal virtues, carefully recorded. It is written in classic Latin, and its thoroughness and conscientiousness certainly entitle it to Dr. Barton's encomium, although it is not the earliest work on this subject. The following extract from his preface is as pertinent to-day as it was a hundred years ago:

"I could not but wonder at the wealth which Bountiful Nature has bestowed upon the inhabitants of America, and the singular liberality with which she has furnished those broad and wide-stretching domains with all the aids, or at least those which are most essential, to the proper treatment of disease. But at the same time I was saddened that so many and such incomparable indigenous remedies should be almost entirely neglected in America itself, or, at best, known to but very few of the natives. For the great majority of those who practise medicine in America, although learned and cultivated men, who have studied the rudiments of the Art of *Machaon* either in the schools of Europe or in the colleges of America, learned their *Materia Medica* from the time-honored compends of European Physicians, and so, following the beaten track, neglect the supply of domestic simples in which their own provinces abound, and, as indeed is the case almost everywhere, look abroad for what they already have in abundance at home.

"Various reasons may be assigned for this neglect. To some a pompous farrago of remedies is distasteful, and, confining themselves to a limited selection of the

more conspicuous medicines, they despise all the rest. Others seem to think it below the dignity of a Physician to make use of simple indigenous remedies. In fine, some are unwilling, and others know not how, to step out of the trodden path. It is not every one who dares incur the risk of introducing a novelty."

In the Ridgway branch of the Philadelphia Library I find a quaint little time-stained volume, published more than a century earlier than the last, and entitled "*The American Physician; or, A Treatise of the Roots, Plants, Trees, Shrubs, Fruit, Herbs, etc., growing in the English Plantations in America. Describing the Place, Time, Names, Kindes, Temperature, Virtues and Uses of them, either for Diet, Physick, etc. Whereunto is added A Discourse of the Cacao Nut Tree, and the Use of its Fruit: with all the Ways of making of Chocolate. The like never extant before.* By W. Hughes. London. Printed by J. C. for William Crook, at the Green Dragon without Temple Bar. 1672."

Although pretentious in its name, however, it is not the work of a physician or of a scientific man, and takes no rank with the elaborate work of the German savant.

The period of our national history in which the Bartons lived was especially fertile in botanical research and authorship. As an appendix to his edition of Robin's "*Florula Ludoviciana*," or *Flora of the State of Louisiana*, Rafinesque gives the following list of botanical works then in process of publication or preparation (1817):

"*Botany of the Southern States, Carolina and Georgia.*" By Stephen Elliot, Esq., Charleston.

"*Descriptio uberior graminum et calamium Americæ Septentrionalis indigenarum et cicurum.*" Auctore D. Henrico Muhlenberg, Philadelphia.

"*Descriptio uberior plantæ Lancastriensis et Americanæ.*" Opus postum. auctore D. Henrico Muhlenberg.

"*Manual of the Botany of the Northern States.*" Albany.

"*Flora Novæ Angliæ, or Botany of the New England States.*" By Dr. Bigelow and Mr. Booth, Boston.

"*Prodromus Floræ Noveboracensis, or Catalogue of the Plants growing within Thirty Miles of New York, with some New*

Species." By Dr. Eddy, Messrs. Torrey and Knevels. New York.

"Flora Philadelphia," By Dr. W. P. C. Barton, Philadelphia.

"Synopsis of the Botany of the United States." By John Leconte, Esq.

"Medical Botany of the United States." By Dr. Bigelow, of Boston.

"Botanical Materia Medica of the United States." By Dr. W. P. C. Barton, Philadelphia.

Botanical Articles in the Journal of the Academy of Natural Sciences of Philadelphia.

Of the valuable and costly work of Dr. Barton I have already spoken.

I must not omit a reference to the superb work of Prof. Jacob Bigelow, of Harvard University, referred to in this list. A native of Sudbury, Mass., he practised medicine successfully for many years in Boston. He early published his "Florula Bostoniensis," and followed it not long after by his "American Medical Botany," in three large octavo volumes beautifully illustrated in color, the drawings having been made by himself. I take them to be the first specimens of chromo-lithography, or at least of printing in colors, ever executed in this country. This work appeared in 1817, and at once commanded marked attention, not only in this country, but in Europe. He also edited, with notes, Sir J. E. Smith's work on Botany, and was one of the committee of five selected in 1820 to form the American Pharmacopœia. In connection with this he is to be credited with the principle of the nomenclature, afterwards adopted by the British Colleges, of substituting a single word for a double in the *materia medica*, wherever practicable. He had the reputation of being an elegant classical scholar, and was as graceful as a writer in the general field of literature as he was able in the preparation of scientific essays. In the preface to the first volume of his "American Medical Botany" he pertinently says,—

"When we consider how small a portion of the vegetable kingdom has been *medically* examined, there can be little doubt that a vast number of active substances, many, perhaps, of specific efficacy, remain for future inquirers to discover. In this respect every successive age is making acquisitions. But a century or two ago the civilized world were unacquainted with the properties of *ipecacuanha*, of *jalap*, of

the Peruvian bark. The powers of *digitalis* in certain diseases are of very recent observation." And later in the same preface he appeals to the patriotism of his medical readers as follows: "It is the policy of every country to convert as far as possible its own productions to use, as a means of multiplying its resources and diminishing its tribute to foreigners. The plants of the United States are various in their character in proportion to the extent of latitudes and climates which our country embraces. . . . A great number of foreign drugs, such as gentian, colombo, chamomile, kino, catechu, cascarilla, cannella, etc., for which we pay a large annual tax to other countries, might in all probability be superseded by the indigenous products of our own. It is certainly better that our own country-people should have the benefit of collecting such articles than that we should pay for them to the Moors of Africa or the Indians of Brazil."

But it was not alone in the making of collections and publishing of treatises that the interest of that day in this most valuable science showed itself. When that enthusiastic young English botanist, Frederick Pursh, author of the "*Flora Americae Septentrionalis*," landed in this country, at the close of the last century, he found no less than four botanical gardens; well stocked, carefully maintained, and comparing very favorably with similar institutions in Europe. These were Marshall's, at Lancaster; the Bartrams', on the banks of the Schuylkill, near Philadelphia, founded under the patronage of Dr. Fothergill; the garden known as the Woodlands, also near Philadelphia, the property of William Hamilton, Esq.; and Dr. Hosack's, in New York, afterwards purchased by the State of New York. Pursh spent eleven years of indefatigable study in this country, and his work, in two volumes, containing accurate descriptions of seven hundred and thirty-nine specimens, and adorned with seventy-four fine engravings, has been a perfect mine for all subsequent investigators.

He was as brave as he was learned and diligent. On two occasions he made exploratory trips of three thousand miles through the pathless mountains and forests of what was then the extreme West, with no other companion than his dog and gun, being for weeks together out of sight of a human habitation or sound of a human

voice. His name has come down to us embalmed in the now fashionable laxative, —the *Rhamnus Purshiana*, or *Cascara Sagrada*.

The only treatise on this subject which American medicine has produced in comparatively recent times, which will at all compare in richness and beauty with the works of Bigelow and Barton, is Carson's "*Illustrations of Medical Botany*."*

This work was produced in five large quartos, the illustrations being life-size. It appeared in 1847. The author says in the preface, "Medical botany has been neglected in this country, not on account of its destitution of interest, but because the facilities of readily prosecuting its study have not been supplied, more particularly in the way of delineation. The connection between *materia medica* and botany is well understood; there is an indebtedness of the former to the latter, and a dependence either for the means of distinguishing between articles or of augmenting their number, too well settled to be controverted. Where an inability to understand the details of this science occurs, it must be a matter of regret to the individual, and cannot arise from any undervaluation of the subject. . . . Apart from the expediency of merely comprehending what is written in the books upon the department, the advantages and gratification experienced by one who has an insight into this scientific mode of description, exemplification, and arrangement will induce him further to pursue it. A wide field of research is opened, to be cultivated with infinite profit to himself, and, should opportunity present, with benefit to science itself."

In the same year with Dr. Carson's beautiful publication appeared an admirable text-book of "*Medical Botany*," the only one ever issued in this country, by Dr. Griffith, of Philadelphia. Since that time, now nearly forty years ago, the development of this important subject has been left almost entirely in the hands of the wholesale druggists.

The vast majority of medical graduates who devote themselves to the practice of their profession live either in the country or in rural towns, where the exigencies of

their practice take them into the country every day. How great are the opportunities of these practitioners, in their long, solitary daily drives, for making themselves thoroughly familiar with the flora of their respective neighborhoods! And how much might they not do towards developing the resources of our native *materia medica*! That such a systematic development is still greatly needed is sufficiently attested by the report made to the American Pharmaceutical Association by Mr. C. Lewis Diehl in 1870. He shows it to be a matter of the greatest difficulty to obtain any reliable information as to the collection of indigenous drugs. "It is a remarkable fact," he says, "that our Louisville druggists depend upon the New York markets for their supplies of indigenous drugs, many of which abound and frequently are collected in our immediate neighborhood. The Kentucky side of the river contributes to our supplies through a few small gatherers, chiefly Germans, but, taken altogether, our home-supplies far from meet the demand of our retail trade."

"Except to the initiated," says Dr. Maisch, in a paper read before the Philadelphia College of Pharmacy, April 16, 1872, "very little is known of the localities where many of the staple articles of the indigenous *materia medica* are collected for the general commerce, the information being usually limited to the geographical section of the country." "Although many of the indigenous plants have been used in domestic and in regular practice, the use of some seems to be altogether confined to certain localities, beyond which their medical properties are unknown or not appreciated."

"It would be very interesting to obtain reliable information concerning them. Dealers in indigenous drugs appear to sell them without questioning their identity, relying upon the statements of the Western collectors. The only way to arrive at correct results is to have complete specimens of the different species collected."

The germ of the science of botany was undoubtedly found in the study of the vegetable portion of the *materia medica* by the pupils of Aristotle. Shall it be said that medicine is unfaithful to its first love, and that the allegiance of more than two thousand years has now come to an end? Certainly it is a matter of importance that the country, if not the city,

* *Illustrations of Medical Botany*, consisting of Colored Figures of the Plants affording the most important Articles of the *Materia Medica*, and Descriptive Letter-press. By Joseph Carson, M.D., Professor of *Materia Medica* in the Philadelphia College of Pharmacy.

practitioner, should be able to distinguish between *dulcamara* and *datura*,—should possess, in other words, clear notions of the general aspect of deleterious plants as contrasted with harmless or beneficent ones. He may, of course, go much farther than this; for, as suggested to me by Dr. Rothrock, Professor of Botany in the Auxiliary Faculty of the Medical Department of the University of Pennsylvania, the mere fact of a plant belonging to a given order may not only determine it as being of therapeutic value, but may indicate the character of its medical efficiency. All gentians, for example, are tonics; most labiates are carminatives or aromatics.

Linnæus expressly says on this subject, "Plants that agree in genus agree in quality; those of the same natural order have nearly similar properties; and those of the same natural class are somewhat similar in their powers."

On this fact De Jussieu based his lectures on *Materia Medica* in the Paris Faculty of Medicine, eighty years ago. There are, of course, exceptions to this law, but the cases in which it holds good are so numerous as to make it of great practical value. It may also add greatly to the esteem in which a country physician is held by his neighbors, if he is able to tell them, on the appearance of a new plant in their neighborhood, its name, habits, and qualities, whether it will prove a friend or a foe, whether it will ruin their pastures or help to fatten their cattle.

Unprofessional men with a smattering of botany have not been slow to take advantage of this flaw in the armor of the regular physician. The result has been the development of a medical sect, who, wisely dropping the name of their father, Thompson, have caused the noble title of eclecticism to become a stench in the nostrils of every honest practitioner. For this we alone are responsible, for we have been unfaithful to our high and holy trust. In Europe, the study of botany is still obligatory upon the medical aspirant. In Sweden, so important is it considered that even the students of the Royal Gymnastic Institute, who intend to practise nothing but the Movement Cure, are compelled to pass a strict examination in it. One of the most thorough and enthusiastic botanists whom I know is a Swedish movement-cure licentiate, formerly one of my assist-

ants. If it be asked why, admitting the value of a knowledge of this science to the physician, it may not be studied after graduation, and be left optional with the individual, I would answer, first, that it is naturally an elementary and preparatory study, like chemistry, teaching us the history and nature of the tools we are to use; secondly, that a previous acquaintance with it will greatly add to the enjoyment and ready understanding of *materia medica*; and, thirdly, that all experience shows that, like other elementary studies, if it is not taken up before the more technically professional branches, it very rarely will be at a later period.

The Medical Society of the State of Pennsylvania, of which I have the honor to be a member, has been for years past silently but surely working for the elevation of the profession, by raising the standard of requirements for acceptance as a student of medicine. At the last meeting a report was adopted by a large majority, establishing a schedule of subjects for examination, and binding the County Societies to subject all applicants for admission into the offices of their members as students to such examination. I append the report in full to this paper. One of the sciences on which the Society has thought it desirable that the candidate should pass an examination is botany. A consideration of the claims of this study upon the attention of physicians generally, and especially of American physicians or those desirous of becoming such, has, therefore, a certain degree of pertinence at the present time.

It has been my aim, in this somewhat disjointed paper, to call attention to those distinguished members of our profession in this country who have delighted to devote their energies to developing our native *materia medica*, and whom the country and the profession have delighted to honor therefor; and, more by their shining examples and in their own forcible language than by argument or eloquence of my own, to stimulate others to renewed interest in this important department of medicine, and to call attention to the fact that this domain is by no means so fully explored that rich discoveries, full of honors to themselves and of benefits to their race and nation, may not await those who will even now thoroughly prepare themselves for its patient exploration.

REMARKS ON A CASE OF CARCINOMATOUS SARCOMA OF THE TESTICLE, AND ON MALIGNANT TUMORS OF THE TESTES.

BY W. G. MACCONNELL, M.D.

AT a recent meeting of the Pathological Society of Philadelphia I had the honor of presenting a specimen of carcinomatous sarcoma of the left testicle,* obtained from the Jefferson Medical College Hospital, from a young man under the care of Prof. John H. Brinton, who removed the diseased organ November 7, 1883.

The growth, in its histological features, is unique; at least I have not been able to find the record of a similar case.

It is claimed by the best authorities that by far the most frequent form of growth met with in this organ is the medullary carcinoma. Thus, Mr. Bryant, in an analysis of seventy-six cases, including the fifty-one cases of Mr. Ludlow, which were analyzed by him in reference to the ages of the patients, claims that they were of this type. Now, whilst so many very eminent authorities make this statement, a conclusion which I imagine to be based upon their gross appearances, I do not find it borne out by my own observations; for in twenty cases of tumors of the testes occurring in this city in the practice of Gross Sr., Agnew, Pancoast Jr., Gross Jr., Brinton, Levis, myself, and others, that I analyzed in reference to their histological characteristics, I found that ten were sarcomata of the round-celled forms, three were sarcomata of the ordinary spindle-celled forms, two were sarcomata of the large spindle-celled forms, three were tuberculous or scrofulous, one was a fibroma, and one was a carcinomatous sarcoma. The ages at which they occurred were from seventeen to twenty to forty years. These conclusions were verified by microscopical examinations, conducted by careful and competent observers. I therefore would award the first rank to the sarcomata in tumors of this organ. Prof. S. D. Gross, in the last edition of his "Surgery," also expresses the same view.

With regard to the location of this form of growth, I have found the disease to be invariably unilateral. The forms of tumors most frequently met with in this organ, in the order of their frequency, are as follows:

1st. Sarcomata.

2d. Chondromata (cystic degeneration may occur as a separate affection, but is more often associated with sarcomata, chondromata, and other growths). Next to the parotid gland, chondroma occurs most frequently in this organ.

3d. Myomata are among the rarest of tumors in this organ, and, when they do occur, are usually associated with carcinoma or sarcoma. Cases have been reported, however, by Billroth, Rokitansky, and Rindfleisch.

4th. Fibromata are the rarest of the tumor-formations in this organ. Cruveilhier has reported one case; Dr. Formad has reported one case. The so-called fibroplastic tumors of this organ, of Lebert and Hovard, may, I think, be relegated to the sarcomata.

5th. Malassez and others have reported cases of lymphadenomata.

6th. Van Buren has reported one case of dermoid cyst of this organ; Virchow records six other cases; Curling has reported ten cases.

The prognosis of sarcomata of the testicles is very unfavorable, the average duration of life, when they run a natural course, being about from ten to twelve months.

Implication of the glands, so rare in sarcomata in other situations, is frequently observed when the testicle is affected: indeed, the glands are more often affected in sarcomata than in carcinomata, so that this symptom affords us no aid in diagnosis. The frequent occurrence of lymphatic involvement tends to show, in the study of the histogenesis of sarcomata of this organ, that by far the greater number (if not all) originate from the endothelial cells of lymph-lacunæ that surrounds the tubules. The absence of glandular involvement in some of the cases that have been noticed can be explained, as was pointed out by Mr. Butlin in *The Lancet*, August 28, 1880, by the short duration of the disease.

Having stated that the prognosis, when the case is left to run its natural course, is very bad, I propose to show, by a few quotations, that an early removal not only prolongs life, but may, if performed soon enough, entirely prevent recurrence. Thus, of twenty-six cases analyzed by Prof. S. W. Gross, "three were well after castration for an average period of six years, two being free from recurrence for two years and one for fourteen years. Three pursued a natural course, and post-mortem showed generalization in

* For history of this case, see p. 217, *post.*—ED.

one, visceral tumors without glandular involvement in two. Of the twenty-six cases, twenty were castrated; of these, one was living with local recurrence and glandular involvement, and nineteen were dead, with glandular implication, and visceral deposits in lungs and osseous system in sixteen. Of these, in eighteen, or sixty-nine per cent., the retroperitoneal glands were the seats of secondary deposits."

Continuing, the same authority states that "of twenty-three patients subjected to operation, three were living at the date of the last reports for an average period of six years (and, strange to say, they belonged to the round-celled variety), one was still alive with local and general reproduction, and nineteen died of generalization of the disease, their average life having been twenty-seven months. Hence castration not only prolongs life, but may effect a cure. The total duration of life from the first observation of the disease until its termination after operation averaged eighteen months for the round-celled and twenty-eight months for the spindle-celled variety, and the former was followed by metastatic tumors in eighteen per cent. more of instances than was the latter."

I may also herewith append Curling's analysis of nine cases living after operation, but which do not seem to have been confirmed by microscopical examinations.

I was living 15 years after.

I " " 5 " "

I " " 7 " "

I " " 12 " "

I " " 9 " "

4 were " 5, 4, 3, and 2 years, respectively.

With reference to date of recurrence, I will give the period of recurrence in thirteen of the cases analyzed by Ludlow: five at two years, four at three years, one at ten years, and three at periods varying from six to eighteen months.

In the seventy-six cases referred to as analyzed by Bryant, which he calls medullary-carcinoma, the ages at which the disease occurred point strongly to the fact that most of them were sarcomata and not carcinomata. Thus:

Before 5 years,	6 cases.
From 15 to 20 years,	2 "
" 21 " 30 "	17 "
" 31 " 40 "	31 "
" 41 " 50 "	11 "
" 51 " 70 "	9 "

250 SOUTH TENTH STREET, December 3, 1883.

FOREIGN BODY IN THE BLADDER SUCCESSFULLY REMOVED BY SUPRA-PUBIC CYSTOTOMY.

BY DONNEL HUGHES, M.D.,

Philadelphia.

G. M., aged 42 years; married; weight, one hundred and sixty pounds; height, five feet ten inches. Has enjoyed good health all his life. While under the influence of liquor, and with a questionable motive, he introduced a steel bonnet-pin (five and a half inches long, having a glass head three-eighths of an inch in diameter) head first into his urethra, and accidentally pushed it out of reach. He first endeavored to remove it with an ordinary pair of tweezers, but, failing to do so, then tried to push the point through the wall of the urethra. While so doing, he snapped it off about one and a half inches from the point. Two hours after the accident I found him in a great deal of pain, with some urethral hemorrhage and a constant desire to urinate. As the point of the pin could be located, and was inaccessible by way of the meatus, I determined to perform external urethrotomy, which successfully removed the smaller portion of the pin. Finding that the other part was not in the urethra, a sound was passed into the bladder, and the remaining portion was very distinctly felt. After a consultation with Drs. John H. Packard and J. P. Stidham, it was determined to remove it by a supra-pubic operation. With the kind assistance of the above-named gentlemen, the following operation was performed. The patient having been etherized, I made an incision in the median line of the abdomen, extending from the symphysis pubis about three inches upward, dividing the skin, fascia, and aponeurosis. The bladder was distended with water, and a lithotomy-staff passed, the handle of which was well depressed between the thighs and firmly held there, in order to make the point of election more prominent. An opening was then made in the bladder about three-quarters of an inch in length, through which the foreign body could be readily felt by the finger and was subsequently removed with the forceps. The abdominal wound was closed with two hare-lip pins; the lower portion of which was occupied by a rubber drainage-tube extending into the bladder. The opening

in the bladder was left for nature to close. The hare-lip pins and drainage-tube were removed on the fourth day. After that time the urine was drawn every two hours with a gum catheter. The after-treatment was fifteen grains of quinine daily, and a two-grain opium suppository every four hours while awake and in pain. The abdominal wound was entirely healed on the eighteenth day, and all the functions of the bladder have been performed without any difficulty since that time.

17 SOUTH FORTIETH STREET, December 5, 1883.

NOTE ON IODOFORM.

BY PHILIP LEIDY, M.D.

FROM time to time recently there have appeared, in various medical journals at home and abroad, paragraphs recommending certain essential oils, such as the expensive oil of rose, geranium, etc., to be used for the purpose of concealing the persistent and disagreeable odor of iodoform. Considering the rank the latter has reached in therapeutics, such concealment is much desired. To add to the list I would recommend the oil of citronella as the most certain and satisfactory. Two drops of the oil to the drachm of iodoform will be found sufficient. It may be used for the same purpose with cod-liver oil when prescribed for external use. The oil itself is used as a rubefacient and anodyne externally, either alone or in combination. I am fully convinced of the advantages claimed for it. The price of the oil is a mere song, and as such is within the reach of all. The oil of chaulmoogra (very expensive), much lauded as an external application for sciatica, etc., I found much enhanced in its therapeutic value by combining with it the oil of citronella in the proportion of one-third of the latter. As it is comparatively little known to the profession in this country, I would recommend a trial, and am sure its use would become more general.

526 MARSHALL STREET, PHILADELPHIA.

POSTAL ARRANGEMENT FOR THE COLOR-BLIND.—It is claimed that many letters went to the Dead-Letter Office because of the inability of color-blind persons to recognize the difference in color between red and green. This is obviated by the law which has just gone into effect of having but one denomination and a uniform rate of letter-postage.

NOTES OF HOSPITAL PRACTICE.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

SERVICE OF L. A. DUHRING, M.D., PROFESSOR OF DISEASES OF THE SKIN IN THE UNIVERSITY OF PENNSYLVANIA.

Reported by HENRY WILE, M.D.

HERPES ZOSTER OF THE FACE.

GENTLEMEN,—This young man, 25 years old, presents an inflammatory eruption on the forehead over the right eye, extending from the eyebrow to the border of the scalp. From the color of the lesions we may infer that the eruption is in a late stage of development,—at any rate, that it is not as acute as it was a few days ago. According to the statement of the patient, it first made its appearance five days ago, in the form of papules, accompanied by an itching, burning sensation around the right eyebrow. He also states that on removing his hat he felt a pain shoot backwards over his head from the right eye. The case is not easy to diagnose, as the lesions appear in a somewhat anomalous form, yet there are sufficient appearances to characterize the lesions as those of herpes zoster. On one patch we see the disease in the vesicopapular stage, the lesions being crowded together in the form of variously sized groups or bunches, and affecting that region of the skin which is supplied by the right supraorbital nerve. They first appear as pin-head-sized papules, which soon pass into vesicles, the latter remaining intact, and at the end of two or three days drying up into crusts. The entire process is an acute one, and runs its course in ten or fifteen days. In the present case the disease is in a very light form; and in this stage, where there are crusts, small papules and vesico-papules, it may be confounded with acne or tubercular syphiloderma, but, bearing in mind the grouping of the lesions, their appearance along the course of certain nerves, and the history of the lesions, there is no difficulty about the diagnosis. No treatment is necessary in this case. The disease is self-limited, and will run its course in about one week; where, however, it is severe it demands treatment. The pathology of the disease shows it to be a nerve-affection, there being an inflammation of the cutaneous nerves, sometimes of the nerve-trunks. The treatment which is found most gratifying is that

by the galvanic current, a light current being used of five or ten cells. After the application the patients often express themselves as being greatly relieved.

As to local applications, one of the best is that of a lotion of the fluid extract of *grindelia robusta*, one drachm to one or two ounces. Another good lotion, and one which is useful in many other affections of the skin, is as follows:

R Zinci sulphat.,
Potassæ sulphuratæ, aa ʒss;
Aquæ, f ʒiijss;
Alcoholis, f ʒss. M.

Sig.—To be dabbed on the part every three or four hours.

*ECZEMA PUSTULOSUM ET PEDICULOSIS
CAPITIS.*

The next case is that of a little girl about 13 years of age, presenting a diseased condition of the scalp in the form of pustules, exudation, and a good deal of crusting. The hair is everywhere matted down by the exudation, doubtless through the agency of the many applications that have been made. In looking for a recent lesion, we find such to consist of small split-pea-sized pustules, and they are for the most part situated on the side of the face and on the back of the head, extending upon the neck. The mother of the patient states that the disease has existed ever since the child was six months old, sometimes being well, but relapsing from time to time.

Whenever we have this matted condition of the hair and the lesions described occurring in a child, we must suspect pediculosis. It often happens in chronic cases of this kind, where numerous applications have been made, that most of the pediculi have been driven away, and but few remain to keep up the mischief, so that it may become a difficult matter to find a *corpus delicti*. We can, however, prove the presence of pediculi by the presence of their ova. In this case, examining the hair on the sides and back of the head, we find them strung with nits, which, being once carefully examined, can hardly be mistaken. The appearance is sometimes simulated in seborrhœa by fine collections of epithelium which adhere to the hair, but in these cases a resort to the microscope will at once remove all doubt.

The case before us is, then, one of pustular eczema, which, judging from the lesions, has existed for some months, and upon which the pediculi became engrafted. A

practical point to be borne in mind in connection with this class of cases is the enlargement of the post-cervical glands. In this case these glands vary in size from a pea to a filbert.

The diagnosis having been made, the treatment is simple. The hair need not be cut, but the head is to be anointed with petroleum, covered with a flannel cap, and allowed to remain over-night. In the morning the scalp is to be washed with soap and water. One or two such applications are all that is necessary to remove the pediculi. Care must be taken not to use too much petroleum, as it may trickle down the back of the neck and produce excoriations. In order to remove the nits, some acid or alkali must be applied and the hair carefully combed. One of the best applications is that of acetic acid diluted, or common vinegar. When the pediculi shall have been removed, we will direct our attention to the eczema and order the use of an ointment of sulphur, one drachm to an ounce of cosmoline.

SYPHILODERMA TUBERCULOSUM.

The patient, a woman 40 years of age, exhibits on the flexor and extensor surfaces of both upper extremities an eruption consisting of flat tubercles, which have melted down, forming patches of a circinate shape, varying in size from a pea to a silver quarter-dollar. About the elbows are also fissured patches which have undergone ulceration, with the formation of crusts. The same formation exists upon the abdomen and about the thighs, the lesions consisting of characteristic crescent-shaped patches of flat tubercles. They are of a dull violaceous color, not coppery as is commonly the case with the tubercular syphiloderm. The scaling is insignificant, and not as in psoriasis, with which this form of disease may be confounded. The patient says that the eruption appeared four or six weeks ago. The lesions, however, look older. They exhibit a tendency to break down and ulcerate, so that unless treatment is at once commenced the disease may extend rapidly and assume a malignant type. The treatment will be internal, and the following will be ordered:

R Hydrarg. biniodid., gr. j;
Potass. iodid., ʒiiss;
Tinct. cinchon. comp., f ʒij;
Syr. aurant. cort., f ʒij. M.

Sig.—One teaspoonful three times a day.

Locally no treatment is necessary, and in two or three weeks we may expect to find a marked improvement.

TRANSLATIONS.

THE INFLUENCE OF DIABETES MELLITUS ON THE FEMALE SEXUAL ORGANS.—The ordinary occurrence late in life of diabetes in women has prevented the confirmation of the occurrence in them of complications of the sexual apparatus analogous to those which so often occur in men.

A case recently reported by Dr. Hofmeier, however, shows that when the disease occurs in young women disturbances of the genital system are also apt to present themselves. The case was one of an unmarried woman, 20 years of age, who had menstruated regularly from her fourteenth year up to one year before the time of the report, when she attended the clinic of the Berlin Hospital for Women for relief from pruritus vulvæ. It was then found on examination that the urine contained large quantities of sugar, and that the uterus was greatly atrophied, being less than 5 c.m. in length. Examination under anæsthesia by Prof. Schroeder revealed that the ovaries were also greatly reduced in size. As all other diseases were excluded, it was concluded that the atrophy was the result of the diabetes.

An examination of the records of the hospital was then made for similar cases. It was there found that of over one thousand cases attending for pruritus vulvæ nearly all had passed the age when menstruation ceases spontaneously. In all of these the examination of the urine for sugar was only omitted in seventeen cases, and of these only three had not reached the usual age of the menopause, and in these latter diabetes could be excluded by the other symptoms. There was only one case on record in which diabetes was present during the child-bearing age, and then, unfortunately, no record was made of the state of the menstrual function. These investigations point to the fact that in women diabetes ordinarily occurs late in life, and explain the apparent exemption of the sexual organs in diabetes in women.—*Berliner Klin. Wochenschr.*, October 15, 1883.

THE PHYSIOLOGICAL AND THERAPEUTIC ACTION OF CAFFEINE.—The following are the conclusions drawn by Dr. Leblond from a study of the physiological action of caffeine:

In physiological doses it is an excitant to the nerve and muscle system and decreases the number of pulsations of the heart, while the blood-pressure is increased by an increase in the vigor of the heart's beats; and by vaso-motor constriction. It reduces the peripheral temperature, and has no effect on the composition or quantity of the urine.

In poisonous doses, caffeine increases the excito-motor energy of the spinal cord, paralyzes the peripheral sensitive nerves, and reduces the irritability of the vagus nerve. In cold-blooded animals the heart beats gradually more and more slowly, and comes to rest in systole; in warm-blooded animals the heart beats faster at the last stage of the poisoning, and stops in diastole. Tetanus of muscular origin is also produced.

As regards its therapeutic application, it is stated that in general its administration is better borne than digitalis. When a commencement is made with small doses, the unpleasant effects which often accompany the use of digitalis are absent. It reduces the rate of the heart and produces a moderate diuresis. Its use is to be preferred to that of digitalis in serious cases requiring prompt treatment, as its effects are prompter and more certain.

The administration of caffeine should always be introduced with a dose not larger than 20 centigrammes, to test the susceptibility of the individual, and then increased to 50 or 75 centigrammes: it is applicable in all cases where digitalis is indicated. It may also be used with benefit in low fevers, where its stimulant effect on the heart and its power of reducing temperature make its employment advantageous: it has also seemed to be of benefit in albuminuria.—*Deutsche Med. Zeit.*, October 11, 1883.

ETIOLOGY OF LEPROSY.—In a monograph entitled *Sull' Etiologia parasitaria della Lepra*, Dr. D. Barduzza, of Pisa, contends that (1) lepra is parasitic and contagious; (2) the contagium is represented by bacteria, which penetrate the organism in the form of threads. It is necessary that the skin shall present a solution of continuity for their admission.—*Gazette Médicale de Nantes*.

EDITORIAL.

THE EXPERIMENTAL PRODUCTION OF DIPHTHERIA.

IN the essay which received the prize offered by the German Surgical Society, Heubner* considers the artificial production of diphtheria from two stand-points: first, the causes of the local infection in human diphtheria, and second, the cause of the general infection. The first part is concerned with the experimental production of the diphtheritic affection of the mucous membrane.

From the investigations of Cohnheim and Litten, who found that temporary arrest of circulation produced the diphtheritic process in the tissues deprived of blood (Weigert's coagulation-necrosis), the author was led to discard the ordinary method of corrosive application to the mucous membrane, and, instead, to employ this method of temporary arrest of circulation. The bladder of the rabbit was the tissue experimented on, and his plan was to ligate the neck of the bladder with a silk thread, and to allow the ligature to remain *in situ* for two hours. The changes in the vesical mucous membrane which followed this interruption of the circulation were then studied upon the following days.

During the first day after the operation there was a marked hemorrhagic oedema of the mucous membrane; its epithelial cells were swollen and loosened. In the second day there occurred a firm, coagulated exudation at the point of the earlier changes, and on the third day genuine diphtheritic patches were found in the mucous membrane, which were in all dis-

cernible respects identical with those occurring in human diphtheria. Subsequently there occurred a "coagulation-necrosis" of the epithelium, mucous and submucous layers of the membrane. This artificial diphtheria, therefore, originated precisely as Cohnheim has postulated,—through the union of violent inflammation and necrosis. The author also proved that the circulation was present in the diseased tissues only shortly before death.

Local membranous exudation, therefore, in man, may be explained as due to a temporary arrest of circulation in the mucous membrane through vascular spasm or through pressure, as by a swollen tonsil. The diphtheria thus produced by the author was not communicable by inoculation to healthy animals.

In the second part of his essay the author sought to produce an artificial synthesis of the local diphtheria and the general infection. He at first inoculated animals in whom this local diphtheria had been produced with the bacilli of splenic fever (*Milzbrandgift*), and found large collections of the bacilli in the diseased localities, but only within the vessels. Animals with artificial local diphtheria were then inoculated with diphtheritic matter from the human subject; the animal died in from two to three days, with all the symptoms of an acute general infection. The same result followed the employment of scarlatinal poison, and the author concludes that the bacilli which were found in both cases cannot be regarded as the diphtheritic poison. For, were this the case, they must be found in the vessels of the diseased membrane in diphtheria in man: he has, however, never succeeded in finding them there, and, moreover, the so-called specific diphtheritic fungus is not essential to the production of the general infection. He concludes, therefore, that the organisms often associated with diphtheria develop as a consequence of the disease, and not the reverse. These conclusions

* Centralblatt für Chirurg., October 20, 1883.

agree in the main with those obtained by Wood and Formad, who deny the specificity of the micrococcus which has been by some supposed to be the agent directly concerned in the propagation of the disease.

THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

WITHIN a few years the College of Physicians of Philadelphia, which, it may be necessary to inform a very few of our readers, is a scientific and social organization of medical men and not a medical school, has certainly entered upon a new and larger sphere of usefulness. Although its membership is restricted, the number of applications for fellowship is increasing, and it has now one hundred and eighty-three names upon the roll, a larger number than ever before. At every meeting this year, we believe without exception, papers have been read, the value of which the demand for the last published volume of *Proceedings* fully attests. At the December meeting, held on the 5th instant, three papers were read, the annual reports of the treasurer and standing committees were received, and nominations were made for officers for the ensuing year. Prof. Stillé, who has so ably presided during the past year, having declined re-election, Dr. Samuel Lewis was nominated for president. Prof. J. M. Da Costa as vice-president, Dr. R. A. Cleeman, secretary, Dr. Charles Stewart Wurts, treasurer, and Dr. J. Ewing Mears, as recorder, were renominated without opposition. Dr. S. Weir Mitchell retired from the Nurse Registry Committee, which now is well established and is a source of income to the library.

The report of the Library Committee, read by the chairman, Dr. Walter L. Atlee, contains some interesting facts. This library, which is the best private medical library in the country, and in size is exceeded only by the library of the Surgeon-

General's Office at Washington, now contains over twenty-six thousand volumes, exclusive of pamphlets and many unbound books.

This annual report showed that there have been added to the library during the past year 2186 volumes, 2107 pamphlets, and 2862 numbers of current journals.

In the collection there are 3381 duplicates, generally in good condition; and the committee wishes to call particular attention to this fact, inasmuch as it affords a rare opportunity to other libraries of augmenting their lists at a comparatively small expense.

The library is directly under the charge of the honorary librarian, Dr. James H. Hutchinson, and employs an assistant librarian and a clerk occupied in cataloguing.

The committee announces that for the ensuing year the library will be kept open, except on Sundays and legal holidays, from 10 A.M. to 5 P.M.

A Committee on Entertainment has been appointed, and, through the liberality of one of the Fellows, an Entertainment Fund has been instituted by a donation of five thousand dollars. Another well-known member of the College has given a large sum towards putting another story on the building, in order to make more room for the rapidly-growing library, and to accommodate the increasing pathological collection in the Mütter Museum, which in some respects stands unrivalled in this country.

A REMOTE DANGER OF ELECTRIC LIGHTING.

THE English medical journals have recently noticed the constant menace to life and health offered by the network of telegraphic, telephonic, and other electrophoric wires overhead in the streets, —public attention having been pointedly directed to the danger by an accident oc-

casioned by the breaking of a wire, which in its fall seriously injured a lady.

In a New York journal (*The Nation*, November 29) is an account of an accident that might easily have been even more disastrous in its consequences. On one of the avenues, a few evenings since, one of the heavy insulated wires belonging to the electric light system, by some means, fell to the ground across the roadway. A horse stepping upon it, there was a momentary flash of light, the horse fell dead, and all the lights on the avenue were extinguished. The account goes on to say that a second horse trod upon the broken wire, and he also fell dead. The streets were cleared by the police, and the wire was soon repaired. The possibility of such an accident happening to a pedestrian is a strong argument in favor of the underground system of conducting the wires; more especially since the experiments upon it in this city, not long ago, fully demonstrated the practicability of this method, which is now being introduced in our principal streets.

PROCEEDINGS OF SOCIETIES.

COLLEGE OF PHYSICIANS.

AT a meeting held November 7, 1883, at the College, the President, Prof. A. Stillé, in the chair, Prof. Roberts Bartholow read a paper entitled

ENTERIC PARAPLEGIA.

By the term enteric paraplegia I intend to express the conception of a spinal paralysis produced by an intestinal disorder. It is a truly reflex paralysis. The fact of the existence of such a malady is denied by many, and indeed most of the reported examples will not bear careful inspection, for it will be found, as I shall show, that they are really cases of ascending neuritis. Eliminating such from the examples of true reflex paraplegia to be found recorded, I intend to place the latter in a special group composed of cases presenting the symptoms of an enteric disease, during the course of which a motor and sensory paraplegia manifests itself and pursues a course obviously dependent on the original lesions. The cases I have lately seen occurred in men over sixty years of age,

and each one presented a morbid complexus so distinctive and uniform as to entitle it to be regarded as a substantive affection,—a pathological entity. Although such cases have been described as examples of reflex paralysis, they have not been adequately differentiated from others similarly classified but of different nature.

Before attempting the task of analysis and differentiation, I must give a brief outline of three cases, the most recent which have come under my observation.

Case I.—Mr. R., æt. 64, merchant and banker, of very vigorous and robust frame, rather spare and bony in outline, but capable of great endurance, called on me a year ago, among other physicians of this city, for relief to an obstinate bowel-affection. His story was this. For a year or more previously he had suffered with intestinal indigestion, colic pains, flatulence, and considerable depression of spirits. Soon after these symptoms were experienced he began to have pain in the back, with more or less band-like constriction of the abdomen, a feeling of numbness in the feet and legs, a strong sense of fatigue in the inferior extremities, followed by weakness and awkwardness of movements in walking, obstinate constipation, and slowness in the emission of urine. For the relief of these alarming symptoms he consulted an eminent practitioner of this city, who diagnosed myelitis, and advised cups, the moxa, and a pill which probably contained ergot. Without using any of the local applications, Mr. R. took the pills, which had a favorable effect in relieving the flatulence and constipation, but presently dysenteric attacks supervened, and then a remarkable change ensued in the spinal symptoms. Up to this period the paraplegia had steadily increased, and walking had become exceedingly difficult, but the change in the condition of the intestine effected a revolution in the state of the spinal functions, and in the course of a few weeks all the paralytic symptoms had disappeared. Still troubled with intestinal indigestion, Mr. R. finally consulted me among others, when I learned the details of the case just given. Very recently I have heard that Mr. R. continues free from the spinal symptoms, and has in the main got rid of his intestinal disorder.

Case II.—Mr. P., a tall, thin, but hardy Quaker farmer, æt. 72. I saw the patient at his home near Delta, York County, this State, in consultation with Dr. Hickman, a very intelligent practitioner living there. I learned that the patient some ten years before had experienced a similar attack, but had recovered rather suddenly under the influence of some remedies which were then prescribed. For some years he remained comparatively free from disorders of digestion. The present attack came on during the past winter. At first there appeared a very considerable dis-

turbance of digestion,—acidity, pyrosis, flatulence, and colic pains. The distress was increased by taking food, and apparently attained its maximum when the alimentary materials entered the intestines. In fact, the symptoms of intestinal indigestion were the most pronounced throughout, and to these was added obstinate constipation, the stool consisting of balls united by masses of mucus or coated with the same. Very soon after the gastro-intestinal catarrh was established, Mr. P. began to experience numbness of the feet and legs and an increasing difficulty of locomotion.

At the time of my visit with Dr. Hickman the patient was nearly entirely disabled. The history of very severe and continuous digestive troubles was repeated. I will, therefore, to occupy as little time as possible, pass on to the objective examination of the paraplegia.

He could not stand without assistance; there was an extreme degree of ataxia; the muscles were so weak that his utmost efforts could not at all hinder slight movement of extension when the legs were flexed on the thigh; the tactile sense was so lowered that the points of the æsthesiometer could not be felt at all; the muscles responded feebly to an induction current; the emission of urine was very slow, and there was much dribbling afterwards; and the bowels were extremely sluggish. There was a feeble knee-jerk.

With attention directed entirely to the digestive trouble, beginning with an exclusive milk diet, in two weeks a marked improvement was manifest in all the symptoms, the paraplegia disappearing. In a letter recently received from Dr. Hickman, I learn that, after a period of very great improvement, Mr. P. began to decline in strength, owing to failure of the functions concerned in nutrition.

Case III.—Mr. McK., of Clearfield County, about 60 years of age, has had for many years frequent attacks of sick-headache. Within the past year, pronounced symptoms of intestinal indigestion, pain of a colicky character, flatulence, and irregular action of the bowels, etc., have come on; but the symptom which has caused the greatest apprehension, and on account of which more especially he has called on me, is an increasing numbness with some diminution of power of the inferior extremities. The tactile, pain, and temperature senses are not abolished, only slightly impaired, and the tendon reflex is unaffected. A feeling of fatigue, of weight and heaviness, is felt in the legs, but locomotion is not as yet much affected. I await further developments in the symptoms referable to the nervous system, but meanwhile treatment is directed to the gastro-intestinal disorder.

Cases similar to those which I have thus briefly outlined have been recorded by vari-

ous observers. An admirable example, and one of the first of its kind, was narrated by that eminent clinician, Graves, of Dublin (*Clinical Medicine*, edition by Neligan, vol. i. p. 558). In this case extreme gastric disturbance, with less important intestinal, came on in distinct paroxysms, varying in duration from several days to two or three weeks, and accompanied by complete motor paraplegia. For a time, entire recovery took place, the paralysis disappearing with the cessation of the other symptoms. Finally the attacks grew so frequent as to be almost continuous, and death ensued from exhaustion. The minutest examination failed to disclose a lesion in any organ of the body. With the advance in our means of investigating morbid states, such cases of presumed functional disease of the nervous system are becoming more and more rare. That there is a condition of reflex paraplegia, due to anæmia of the cord, is a postulate I expect to maintain. That there is, however, a so-called reflex paraplegia connected with diseases of the gastro-intestinal and genito-urinary tracts, which is not truly reflex, is another postulate that I believe to be susceptible of demonstration.

There was a period, in England more especially, when the notion of reflex paraplegia secondary to intestinal, renal, and genital disease was widely entertained. The cases first reported by Stanley (*Medico-Chirurgical Transactions*, vol. xviii. p. 260); Brodie ("Lectures on Urinary Organs," p. 115), Stokes ("Practice of Medicine, Treatment of Nervous Diseases"), Graves, and others, were supplemented by the striking narratives of Gull (*Guy's Hospital Reports*, various papers). Then Brown-Séquard ("Lectures on Paralysis," etc., 1861) gave a scientific explanation of the mechanism, referring the paralysis to vaso-motor action. It must be admitted, nevertheless, that the doctrine of a reflex paralysis has not maintained the position it once had. In no modern work is the subject treated with the extent and gravity befitting an important disease.

The two postulates I purpose to sustain are—

1. That there is a reflex paraplegia due to a functional disturbance of the intestine,—enteric paraplegia.

2. That there is a paraplegia having its initial seat in the end-organs of the nerves distributed to the mucous membrane, thence ascending to the cord by a progressive neuritis.

As respects the first postulate, the cases I have narrated, and many others on record, demonstrate a causal connection between the enteric disorder and the spinal. That the paraplegia is functional is proved by its prompt cessation when the cause is removed.

One of the means of determining whether a given paraplegia is due to a myelitis or to mere anæmia—that is, functional—is the sub-

cutaneous injection of strychnine. At a late meeting of the American Neurological Association, Dr. Jewell, of Chicago, recounted his experiences with considerable doses of strychnine in cases of paraplegia, which improved so remarkably that they must have belonged to the merely functional group. It is in a high degree probable that cases of merely reflex paraplegia,—of enteric paraplegia,—especially as they occur in aged subjects, are relatively frequent, and happen from a degree of intestinal disturbance that seems a mere accident of the morbid complexus.

What is the mechanism? We are helped in our consideration of this question by physiological data. Kussmaul and Tenner (quoted by Erb) have shown that sufficient loss of blood will cause paraplegia. Tying the abdominal aorta, and its obstruction by disease,—of which Gull (*Guy's Hospital Reports*, 1858, p. 311) has given a striking example,—embolic blocking of the spinal vessels, as Panum (*Virchow's Archiv*, Band xxv.) has experimentally demonstrated, and large uterine hemorrhage, as Moutard-Martin (*L'Union Médicale*, 1852) has shown, have alike stopped the spinal cord functioning. In other words, an insufficient blood-supply—an anæmia—is a cause of paraplegia. Brown-Séquard, in his Lectures, published in 1861, maintained the thesis that a strong contraction of the vessels of the cord induced by reflex stimulation is the essential condition in reflex paraplegia. We should not lose sight, in this connection, of the degree of stimulation necessary. A moderate degree of intestinal irritation suffices; for the law of reflex contraction of the vaso-motor fibres may be formulated thus: irritation of the end-organs of the sensory nerves, not too violent and long-continued, stimulates the vaso-motor centre in the medulla, and causes a general contraction of the arterioles; but excessive and protracted irritation depresses the vaso-motor centre and relaxes the vessels. It seems probable that an ordinary intestinal indigestion and the stretching of the nerve-fibres produced by retained gas is a degree of irritation sufficient to produce the supposed effect. To the further elucidation of the mechanism of enteric paraplegia, it is necessary to recall the fact that the blood-pressure in the vessels of the intra-abdominal organs rises and falls within considerable limits in quite an independent manner, controlled, doubtless, by the same ganglia that regulate the calibre of the intra-spinal blood-vessels.

The circulation within the spinal canal is peculiar, in that the veins bear such a disproportionate volume to the arteries, and that the whole vascular supply is in a certain sense a diverticulum. Athérroma of the vessels will contribute to the result of reflex irritation; and hence it is that paraplegia has resulted from endarteritis of the spinal vessels.

The second postulate is that the paraplegia

which succeeds to certain cases of enteric, renal, or genital disease is due to an ascending neuritis. Chronic dysentery, pyelitis, and vesical catarrh are affections during the course of which the spinal cord has become diseased. Lesions of continuity involving the terminal nerves in structural changes are necessary to the production of this effect. The part which ascending neuritis may play in causing anatomical alterations of the spinal cord is exhaustively shown by Friedreich in his monumental work on progressive muscular atrophy (*Ueber progressive Muskelatrophie, über wahre und falsche Muskelhypertrophie*, Berlin, 1873, Hirschwald). Whether we accept his conclusions or deny them, we cannot withhold the full measure of admiration for his labors. Starting with the theory of an intramuscular neuritis, Friedreich holds that by an extension of this affection upwards the cord is ultimately reached and the changes belonging to progressive muscular atrophy are wrought. The intramuscular neuritis admitted, the rest may easily follow. Under the term "Chronic Ascending Neuritis," Duménil has described the changes in injured nerves which, caused by trauma, proceed from the point of injury up to and involve the cord. Vulpian has especially demonstrated the modifications produced in the spinal cord by the section of a principal nerve in a member, usually the sciatic (*Archives de Physiologie Normale et Pathologique*, No. 3, 1868, p. 443). The nerves of a limb amputated, as Dickinson has especially shown, undergo degenerative atrophy, and that part of the spinal cord in anatomical connection therewith also atrophies. Many other observations might be quoted, but these will suffice to show how changes in the cord follow injuries to peripheral nerves.

In paraplegia secondary to ulceration of the mucous membrane, we can readily, I think, conceive of a lesion of the peripheral nerves, and an ascending neuritis, to which the succeeding changes are due. It follows that such cases require a very different prognosis from those of simple reflex paralysis. The course and termination of the latter are affected by the causal lesions, whilst the former pursue a steadily unfavorable direction from the beginning of the spinal symptoms. The differentiation of reflex from secondary paraplegia is made by attention to the following points:

Reflex paraplegia is sudden in its onset, or, at least, develops quickly; secondary paraplegia is gradual in its evolution: the former is soon complete in all points of its symptomatology; the latter attacks one spinal function at a time. Reflex paraplegia follows the fortunes of the producing malady; secondary paraplegia pursues an independent course, and when the alterations begin in the spinal elements they proceed in their own way, just as after amputation of a limb the changes

of the cord go on in the associated nerve-fibres, or as in Landry's ascending paralysis the lesions proceed by contiguity of tissue. Reflex paraplegia, of and by itself, never proves fatal, nor does it inflict permanent damage; secondary paraplegia may be the cause of death, and, if not fatal, effects lasting mischief.

To this view of reflex paraplegia it may be objected that extreme variations in the vascular supply must ultimately lead to structural changes. This is certainly possible; but the spinal circulation, like the cerebral, is arranged to permit considerable variations in the amount of blood.

It remains to explain, if an explanation be possible, why intestinal or renal lesions may in one case produce a merely reflex disturbance and in another set up an ascending neuritis. There are, probably, two reasons: 1st, the depth and extent of the peripheric lesions; 2d, an inherent susceptibility to degenerative changes in the nervous elements. The first, to me, has profound significance, and I have already alluded to it. A degree of peripheric irritation not too great will merely stimulate the vaso-motor centres, and cause anæmia of the cord by tonic contraction of its vessels; but when the lesions of the mucous membrane are of a destructive kind, depression of the trophic centres, as well as of the vaso-motor, ensues. That there is a neuropathic type of constitution, in which the nerve-tissues are peculiarly prone to take on morbid changes, is an indisputable fact. When the two influences coincide, the result is not doubtful.

I must, then, conclude that there is a malady which may properly be entitled *Enteric Paraplegia*.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, November 22, 1883.

The President, Dr. TYSON, in the chair.

Large intestines from two cases of chronic dysentery, one of the specimens showing pseudo-polypi. Presented by J. H. MUSSER, M.D.

CASE I.—The patient had chronic dysentery; further clinical information not given, and no record of autopsy preserved. The specimen is from the museum of the Presbyterian Hospital, and I present it to-night on account of its rarity. It is a part of the large intestine, fourteen inches long. To the naked eye it shows thickening of the mucous and submucous layers and hypertrophy of the muscular layer. On the surface of the mucous coat innumerable polypoid growths are observed, some pedunculated, some sessile. The sessile growths are from the size of a millet-seed to that of a chestnut, round or ovoid. The others also vary in size

from a pea to a large bean; their pedicle is generally one-sixteenth to one-eighth of an inch long. The reporter remembers seeing the specimen when recently removed, and knows there were more pseudo-polypi than are here visible, many having fallen off from handling, etc.; that there was scarcely any healthy mucous membrane; that in this part of the intestine there was almost complete ulceration of the mucous coat. At one point a large stellate cicatrix, depressed in the centre, is noticeable, while all over the surface cicatricial lines are observed, most distinct about the bases of the growths.

Remarks.—In connection with this specimen, I would like to call the attention of the members to a minute description of a similar specimen by Dr. Woodward. His article may be found in the *American Journal of the Medical Sciences* for January, 1881, and is entitled "Pseudo-Polypi of the Colon: an Anomalous Result of Follicular Ulceration." According to the writer, the origin and development of these polypi is as follows: 1st. A granulating ulcerated surface of the intestine. 2d. Numerous islets of mucous membrane on this surface. 3d. "The formation of cicatricial contractions commenced in the infiltrated submucosa, constricting the margins of the islets of mucous membrane, which were further transformed by hyperplastic inflammatory processes until ultimately they acquired the form of pedunculated excrescences and projected into the lumen of the intestine, like so many little polypi,"—being pushed out by the contraction of the connective tissue. Although the surface of the mucous membrane appeared to the naked eye healthy, with the microscope it showed it was submucous connective tissue infiltrated with lymphoid elements. The pseudo-polypus was composed of a central portion of connective tissue and a peripheral portion of diseased mucous membrane, the former continuous with the submucous layer, the latter limited to the surface of the growth. The histological changes in the mucous and submucous layers resembled those of chronic inflammation. The remainder of the bowel showed follicular ulceration. I am unable to say what was the condition of other parts of the bowel in the specimen exhibited.

Case II.—For this specimen I am indebted to Dr. Gittings, of West Philadelphia, for whom I made the autopsy. It was removed from a well-known druggist of this city, who had been a sufferer from chronic dysentery for some time. The bowel-affection was especially severe during the past summer. He had been ill of an acute exacerbation for about one week when Dr. Gittings was asked to see him. The symptoms were of an acute dysentery, but not alarming. The effects of the habit of using chloroform, chloral, and alcoholics to excess, which habit he continued during his illness, complicated the clinical features. About the tenth day of his illness

the typhoid state suddenly developed, and he died in coma two days thereafter. His temperature never was higher than 102°; tormina and tenesmus were marked, bloody and mucous discharges were excessive.

Autopsy, eighteen hours after death.—Rigor mortis marked. Body well nourished. On section, the abdominal walls were loaded with fat, and large deposits of this tissue were found in the great and lesser omentum, the meso-colon, and the epiploicæ. The mesenteric and lumbar lymphatic glands were not enlarged. The cæcum was surrounded by old lymph, the appendix bound down by adhesions and thickened. The cæcum was dilated, the transverse and descending colon contracted; the walls of the entire colon were thickened. On opening the large intestine it was found to be extensively ulcerated. The mucous membrane and the ulcers were strikingly anæmic and of a pale cream-color; there were no points of hemorrhage. The walls were thickened; the mucous membrane was swollen; the ulcers were more numerous and larger in size at the cæcum. The smaller ulcers were the size of a dime; some of the larger extended around the gut, and were one-half inch to an inch wide. The edges of the ulcers were regular, bevelled, and thickened, the floor rather clean; the deepest did not extend beyond the muscular coat, the more superficial only included the mucous membrane. The larger ulcers were on the tops of the folds of the intestines. A tenacious, thick mucus covered alike the ulcers and the adjacent structures.

Condition of other organs.—Liver enlarged and fatty. Kidneys markedly cirrhotic. Spleen normal. Heart slightly hypertrophied.

Microscopical examination revealed the changes in the intestine of chronic inflammation, and that the ulceration was of a simple nature and not due to tubercle.

Case of carcinomatous sarcoma of the left testicle. Presented by Dr. W. G. MACCONNELL.

This specimen was removed from a young man by Prof. Brinton, at the surgical clinic of the Jefferson Medical College Hospital, on Wednesday, November 7, 1883.

History.—Jacob A., æt. 26 years, a clerk: about eighteen months ago he struck his testicle, in mounting his horse, on the pommel of the saddle, from the pain of which he fainted. No inflammatory enlargement, however, of the organ ensued. Last May he noticed that the left testicle had begun to enlarge, which continuously increased in size until it had attained its present volume. There was a sense of heaviness in the tumor, but no pain was experienced until about two weeks prior to its removal, when he noticed a periodical pain, of a burning nature, which, with the increasing size of the organ, caused him to apply for relief. It weighs about eight

ounces, and measures in its long diameter four and a half inches, transversely three and a quarter inches, and about two and a quarter inches in thickness. No lymphatic involvement was present, nor was the cord involved. The veins of the scrotum were enlarged and prominent. The tunica vaginalis testis is slightly thickened and very opaque. The tunica albuginea is also thickened. A slight remnant of the epididymis exists in the form of a small fibrous lump. Its shape is somewhat that of a kidney, and upon section showed a moderately firm, buffy-colored tissue. It did not cry under the knife. In color and consistence it resembled the soft fibromata. Distinct remains of the fibrous septa are to be seen. There are no cystic changes nor any chondroid tissue present. Its microscopical appearance and consistence suggested a spindle-celled sarcoma; and as such, upon section, I diagnosed it. Microscopically, at a first examination, from the great ecstacy of the epithelium present I was inclined to regard it as a pure medullary carcinoma; but, after a careful study of several sections, I am inclined, by reason of the juvenescence of the connective tissue, both round and spindle cells being present, to call it a carcinomatous sarcoma. There was no history of syphilis, scrofula, or tubercle, nor had any member of his family ever labored under any form of tumor.

Dr. NANCREDE called attention to the fact that modern microscopic study has shown that carcinoma of the testicle is a rare disease; most malignant tumors of that organ being really sarcomata. In this connection it is of much practical interest to note that the system becomes infected at a relatively late period of the disease, so that when a sarcomatous testicle is removed at an early stage of the disease, prolonged immunity, if not actual cure, may result. The inguinal and retroperitoneal glands were those usually affected, their enlargement, by pressure, pain, etc., being the ultimate cause of death. Even more distant lymphatic glands are in rare cases involved.

Dr. FORMAD agreed with Dr. Nancrede. Some years back he had paid special attention to the study of malignant growths of the testicle and ovary. Of the former he had examined thirty cases, all of which were sarcomata. He did not believe in the existence of such a growth as true carcinoma of either the testicle, ovary, or kidney. The so-called carcinoma of those organs exhibits cells of a *connective-tissue* type rather than of an epithelial. Dr. Formad considered, with many other observers, that the so-called epithelial cells of kidney, testicle, and ovary are really *endothelial*, and gave reasons in support of this view. He further said that there is a variety of endothelial carcinoma occurring in the breast, which is that usually described as alveolar sarcoma. Here the endothelial cells of the

lymph-spaces proliferate, but the glandular elements of the mammæ do not participate. It is doubtless from the examination of such tumors that Virchow, and Cornil and Ranvier, have gained the erroneous idea that true carcinoma takes its origin from connective tissue. The speaker would suggest the term "*endothelial carcinoma*" for such tumors instead of "alveolar sarcoma."

Dr. DAVIS could not think that Dr. Formad was correct in absolutely denying the existence of carcinoma of the testicle, ovary, and kidney.

Dr. MACCONNELL agreed with Dr. Nancrede as to the relative frequency of sarcoma of the testis, having examined a large number of such specimens. He could support the views of Dr. Formad as to the growths of the testicle originating largely in proliferation of the endothelia of the lymph-spaces and tracts.

Sarcoma of the breast. Presented by Dr. G. E. DE SCHWEINITZ.

Some weeks ago, I had the pleasure, through the kindness of Dr. Ashhurst, of exhibiting a specimen of cysto-sarcoma of the female breast, and to-night I am once more indebted to him for the privilege of showing this tumor, also a cysto-sarcoma, but differing in type from the previous growth. It is another instance of the truth of the remark, so justly made by Rindfleisch, that the expression cysto-sarcoma is by no means to be conceived as the designation of a definite, perhaps round-celled sarcoma, with cysts, but it only tells us that a new formation with the textural character of histoid tumors had attacked the mamma and dilated its pre-formed cavities.

This growth was removed from the person of a lady of middle age, married, but childless. She assigns no cause for its appearance. The growth of the tumor has been slow, it having originally been noticed six years prior to the date of operation. The weight of the mass immediately after removal was three pounds and one ounce. On palpation there was a distinct sense of fluctuation. The skin over the tumor was discolored, but not adherent. On section the growth is seen to be composed of two parts, the one about the size of a closed fist and the other somewhat smaller. The section evacuated a quantity of bloody, mucus-like fluid. The centre of each mass is seen to be cystic, or, rather, the masses are the papillary and irregular excrescences which have protruded into the dilated ducts. The growth is composed of numbers of variously-shaped nodules, whitish or yellowish-white in color, but in some spots semi-translucent and resembling somewhat colloid material. The microscopic examination of various portions shows a similar result, differing only in degree; large round-celled sarcoma tissue, and some spindle cells,

generally diffuse, but in places tending to alveolar arrangement, here and there round, stellate, and spindle cells branched and anastomosing (mucoid tissue), numerous blood-vessels, usually wall-less, or mere channels passing through the tissue. In many places the sections show the enlarged ducts cut transversely and lined with a single layer of columnar epithelium. Surrounding them is a dense matrix of connective tissue. It may not be uninteresting to state that the specimen has been preserved in a solution of hydrate of chloral (gr. xx- $\frac{3}{4}$), after the manner originally recommended by Dr. W. W. Keen, with what success the beautifully-fresh and natural appearance of the growth plainly attests.

C. B. NANCREDE,
Recorder.

NEW YORK PATHOLOGICAL SOCIETY.

A REGULAR meeting was held November 28, 1883, GEORGE F. SHRADY, M.D., President, in the chair.

HYDROCEPHALUS.

Dr. H. N. HEINEMAN presented the brain of a child who died at about the age of two years, at the Mount Sinai Hospital, with the history that when about two months old it fell upon the head from a chair, since which time it had not been well. There had also been an eruption upon the body. About the twelfth month the head measured in its occipito-frontal diameter twenty-three centimetres, and from ear to ear posteriorly fourteen centimetres. There was a perceptible increase in size the last six weeks of life. There was an elevation of temperature preceding death; some vomiting; no convulsions. The patient lay in bed, with the head resting upon a pillow. It was quite small for a child two years of age: at death the body weighed twelve pounds. The chief interest of the case related to the brain, the convolutions of which had been greatly thinned and unfolded by the action of the fluid within the ventricles. The fluid amounted to more than a quart. There was no distention of the central canal of the cord. There was slight broncho-pneumonia, which probably had been the immediate cause of death.

SARCOMATOUS TUMOR OF THE STERNUM.

Dr. CHARLES HEITZMAN presented the specimen, and said that the patient, a physician, had come to him in April, 1882, to have his blood examined under the microscope, thinking that he was suffering from leucocythæmia. Dr. Heitzman found the opposite condition from what the patient expected,—a diminished rather than an increased number of the colorless blood-corpuscles. Afterwards, some specimens of fluid obtained by aspiration of a small tumor over the sternum were

sent him for examination, but the first examination was negative. The last specimen, however, presented appearances which were believed to indicate approaching dissolution. The patient died, and at the autopsy the body was found greatly emaciated. The tumor over the sternum, now the size of a large egg, communicated, through a small opening in the sternum, only large enough to admit the little finger, with a cavity in the anterior mediastinum below, which contained blood. The pleura and the apices of the lungs were transformed into dense, fibrous connective tissue, believed not to be of malignant character. The tumor itself was a sarcoma. The spleen was enlarged and very firm. The patient had suffered from malaria. The liver was the seat of interstitial hepatitis.

In reply to a question, Dr. Lange said that clinically the tumor had been regarded as a sarcoma.

Dr. HEINEMAN thought it was the rule that in carcinoma and sarcoma of the lungs and in pleura the diagnosis was not made out during life.

Dr. VAN GIESON referred to a case in which the malignant process commenced in the lung and extended to the sternum, and in which there had been no difficulty of diagnosis. Statistics of a large number of cases gave a correct diagnosis during life in forty-five per cent.

Dr. HEITZMAN had once made the diagnosis of sarcoma of the lung from the presence in the sputa of a large number of globular elements, smaller in size than pus-globules. A diagnosis of carcinoma of the lung had been made by the physicians in charge. The autopsy showed sarcoma.

ACUTE PYÆMIA OF URETHRAL ORIGIN.

Dr. G. L. PEABODY presented the heart of a man who had died of acute pyæmia of several days' duration, following the introduction of a sound into the urethra. There had been stricture at the bulbous portion, necessitating the use of the catheter. When the sound, No. 15, was passed, but little injury was believed to have been produced. Notwithstanding, a chill and fever followed, and led to death. Pericarditis and endocarditis had been diagnosed during life. At the autopsy there were found well-marked signs of pericarditis and ulcerating endocarditis, and also commencing abscess of the kidney-structure. In the blood-vessels in the neighborhood of the abscesses in both the kidneys and the heart were large numbers of micrococci.

GREAT DILATATION OF THE URETER IN A CHILD.

Dr. R. VAN SANTVOORD presented the ureters of a child, 12 years of age, who was admitted to the Randall's Island Hospital, with the following history. At the sixth month of age an operation, the nature of which could

not be learned, was performed for spina bifida, the cause of paraplegia and of paralysis of the sphincter of the rectum and of the bladder. The operation resulted in cure of the spina bifida, with return of power to the legs and the sphincter ani; the difficulty with urination continued. A catheter was passed on admission to the hospital, and a quart of urine withdrawn. The catheter continued to be passed daily. The patient lost appetite, had nausea and fever; the urine was turbid and contained pus and albumen. Death took place in three months, from exhaustion. At the autopsy the vesical walls were much thickened and sacculated, the left ureter enormously distended, being larger than the small intestine. The pelvis of the kidney was also dilated, and the organ itself contained abscesses. The right ureter was less dilated, and the right kidney also contained abscesses. They were not permitted to examine the spinal cord.

EXTIRPATION OF METACARPAL BONES FOR BUNION.

Dr. L. H. SAYRE presented metacarpal bones removed from both feet of a man who had suffered for years from bunions which had given much trouble and on two occasions had been the seat of ulceration. An incision was made on the dorsal aspect of the members, the affected metacarpal bones were removed with the bone forceps, and the edges of the wounds were closed with black silk. Union took place inside of two weeks, and the patient was soon able to be about with comfort, and had a movable joint.

ULCERATION OF STOMACH PRODUCING FATAL HEMORRHAGE—OBSCURE SYMPTOMS.

Dr. BEVERLY ROBINSON presented the specimen, which was removed from a man, a salesman, who entered St. Luke's Hospital, having suffered for some time with difficulty of breathing and cardiac palpitation. On admission there was slight mental alienation; the feet were œdematous; there was some albumen in the urine; there was double pleuritic effusion; the heart was enlarged and dilated. His condition changed but little until November 19, when his face was observed to be very pale. He was breathing with difficulty, and in this condition he soon died. A considerable serous effusion into the pleural cavities was found; the heart was dilated; there was no valvular lesion; the lungs were in a state of brown induration; the stomach was distended with blood, which had escaped from an open blood-vessel at the seat of an ulcer at the pyloric orifice. The interest of the case was the presence of so large an ulcer, and of internal hemorrhage resulting in death, with so obscure symptoms. It was remembered that there had been some discharge of a bloody fluid from the rectum the evening previous to death. Digestion had been good.

PARIETAL ABSCESS—MENINGITIS—DEATH.

Dr. W. P. NORTHRUP presented the skull and brain of a child which died when about eight months old, having had for two weeks preceding death an abscess of the right parietal bone. The cause of the abscess was unknown, and the symptoms produced were very slight, such as scarcely to attract attention. There was some irritability, hyperæsthesia, and stiffness of the muscles of the neck. At the autopsy the convexity of the brain was coated by a thick layer of pus; no direct relation could be traced between the parietal abscess and the inflammation of the membranes of the brain pathologically.

Dr. W. M. CARPENTER asked if the meningitis might not have developed independently of the external abscess.

Dr. PETERS remarked that a number of cases had been published in the Transactions in which direct extension of the inflammatory process could not be traced from the external abscess to the membranes within.

A VERY THIN SKULL.

Dr. J. A. WYETH presented part of a skull which had broken to pieces with a slight blow of the hammer when he was about to open it for demonstration to his class. The bone was but little more than one-sixteenth of an inch thick. He inquired, would not this condition explain how fracture and death occurred in some cases where but a slight blow had been inflicted upon the head?

PHILADELPHIA COUNTY MEDICAL SOCIETY.

AT a conversational meeting, held at the hall of the College of Physicians, Philadelphia, November 21, 1883, Dr. William M. Welch, President of the Society, in the chair, Dr. J. H. Musser read a paper entitled

FURTHER NOTES ON THE USE OF HAMAMELIS IN THE TREATMENT OF VARICOSED VEINS.

After referring to his original paper in the *Medical Times*,* which first called attention to the use of hamamelis in the treatment of varicose veins and their sequences, he reported the subsequent experience of a number of clinical observers upon its effects, several of which confirmed his statements as to the value of the remedy in varicose veins. The fluid extract—a dark-colored preparation—is used in doses of a drachm three or four times daily. It had also been found useful in phlebitis of chronic Bright's disease, hæmaturia, menorrhagia, and bleeding hemorrhoids; cases of which were mentioned in the communications he had received in response to the original paper. The combined testimony

shows that the remedy has a decided effect upon the venous structures.

NOTE ON PARALDEHYDE AS AN HYPNOTIC.

J. C. Wilson, M.D., read a note upon paraldehyde, in which he gave a description of its physical characters and chemical constitution. A limpid fluid of an ethereal taste and odor, it may be administered internally in doses of half a fluidrachm to two fluidrachms well diluted with water. Given in this way, it produces drowsiness without preliminary excitement, and it has been utilized by Italian physicians in dementia paralytica, in hysteria, and in other forms of disorder of the nervous system. In several cases mentioned by the lecturer it acted well as an hypnotic, its usefulness being shown most markedly in a gentleman suffering with depression and sleeplessness after a debauch, upon whom bromide of potassium and chloral, in reasonable doses, failed to have any influence. In its action it most resembles chloral, and it may prove a useful addition to our sleep-producing drugs.

REVIEWS AND BOOK NOTICES.

THE MEDICAL STUDENT'S MANUAL OF CHEMISTRY. By R. A. WITTHAUS, A.M., M.D., Professor of Chemistry and Toxicology in the University of Buffalo and the University of Vermont, Professor of Physiological Chemistry in the University of the City of New York, Chemist to the City of Buffalo, etc. Wm. Wood & Co., New York. 8vo, pp. 356.

While occupying the position of municipal chemist, and filling the chairs of chemistry in three colleges in cities far separated, Dr. Witthaus has found time to produce two textbooks. The Student's Manual is, in a measure, a new edition of the "General Medical Chemistry," written by Dr. Witthaus for Wood's Library of 1881. Medical students will find it generally satisfactory, as it contains more or less information on all of the more ordinary chemical compounds, as well as many of the rarer substances.

Due prominence is given to the description and instructions for examination of constituents of the body, urine, etc. It is to be regretted, however, that the details of analytical methods are printed in type so small as to tax the eyes severely.

That portion of the book devoted to the compounds of carbon is rather more extended than required in a work intended for students. Indeed, the molecular structure of carbon compounds, as here explained, could hardly be understood by one who had not already studied the subject, in which case the graphic formulæ would be superfluous.

Dr. Witthaus has abandoned, as arbitrary and unscientific, the classification of the ele-

* For April 21, 1883.

ments as metals and non-metals, but retains the terms metal and non-metal for the sake of convenience.

We notice that glucinum is classed with aluminium, while its atomic weight as given would require its introduction into the magnesium group.

Considering the difficulties in the way of combining the chemistry of the Pharmacopœia, general, medical, hygienic, with theoretical chemistry, we think that Dr. Witthaus has fairly succeeded in his task. G.

THE COLLECTIVE INVESTIGATION OF DIPHTHERIA, AS CONDUCTED BY THE THERAPEUTIC GAZETTE, DETROIT, MICHIGAN. WITH AN EDITORIAL SUMMARY BY J. J. MULHERON, M.D. Detroit, G. S. Davis, 1883. 8vo, pp. 120.

This book is made up of the replies of one hundred and four practitioners in the United States, of three in Canada, and of one in an unaccredited locality, to the following queries:

"1. What is your opinion in regard to the local or constitutional nature and treatment of diphtheria?

"2. On what clinical facts observed by you do you base your opinion?

"3. What is your opinion as to the contagiousness of diphtheria?

"4. What facts in your experience bearing upon this question?

"5. What microscopic examination, if any, have you made of the diphtheritic membrane?

"6. What measures, if any, have you adopted by way of prophylaxis, and what success has attended those efforts?

"7. What local treatment have you found most efficacious?

"8. What general treatment has been most successful in your hands?"

The replies are in many instances as vague as the questions, and embody views almost as diverse as the localities whence they come. This does not, however, relieve in the slightest degree the sense of annoyance produced by one hundred and eight repetitions of more or less concisely expressed opinions upon the same subject,—an iteration altogether beyond that to which it has grown customary to apply an adjective by no means polite. Nor is the editor's summary of this scattering vote altogether satisfactory. It seems an expression of his personal views of the matter rather than those of the majority represented. The result would have been by far more valuable if the questions had been so framed as to accumulate *observed facts* rather than *mere opinions*. No one would expect to obtain satisfactory knowledge of the depth of a body of water by questioning the men composing the crew of a ship sailing it. The man heaving the lead would know, but the others would be able only to guess at it. Moreover, the depth is not everywhere the same. To consult the charts of the coast survey would give

definite information. Where no such charts exist, or where they are incomplete, it behooves those interested to collect with all diligence the facts (not any man's opinion) with which to construct them. The etiology and pathology of diphtheria are yet involved in the most dense obscurity. Laborious research, conducted in the spirit of science, proceeding step by step, alone is capable of the solution of such questions. That is not the method pursued in the investigation of which this volume is the record. If ten times one hundred and eight practitioners had contributed to it, the advancement of knowledge would have been just the same. J. C. W.

A DICTIONARY OF THE ENGLISH LANGUAGE. By JOSEPH E. WORCESTER, LL.D. New Edition, with Supplement. Philadelphia, J. B. Lippincott & Co., 1883. Quarto, pp. 2058.

Worcester's Dictionary of the English Language, which in the recent edition is the most complete ever published, as a work of reference is thorough, accurate, and trustworthy. It has been adopted as the standard authority for the English language by distinguished men of letters and scholars of this country, by the various departments of our national government, and by the great newspapers. The present edition of this classical work contains over a hundred thousand words, twenty thousand more than any preceding work of the kind, its definitions are clear, satisfactory, and concise, it is well printed and amply illustrated. It also contains chapters upon Principles of Pronunciation; Orthography; English Grammar; Origin, Formation, and Etymology of the English Language; Archaisms, Provincialisms, and Americanisms; History of English Lexicography; Pronunciation of Greek and Latin Proper Names; Scripture Proper Names; Modern Geographical Names; Names of Distinguished Men of Modern Times; Abbreviations used in Writing and Printing; Words, Phrases, and Quotations from the Greek, Latin, French, Italian, and Spanish Languages; and a Supplement, with Additional Vocabulary and Synonymes. At the present time, when a special effort is being made to sell dictionaries to professional men, we think it proper to call the attention of physicians to the importance of having a copy of "the Standard English Dictionary" for reference in all cases of doubt or dispute as to orthography, orthoëpy, or definition. For professional men there is no rival to Worcester; without it no library is complete; with it other English dictionaries are, for ordinary use, superfluous.

A TREATISE ON THERAPEUTICS. By H. C. WOOD. Fifth Edition. Philadelphia, J. B. Lippincott & Co., 1883.

This work has been in its successive editions so thoroughly reviewed in these columns

that we cannot accord more space than is necessary for the announcement of the rapidly succeeding revisions: indeed, latterly the editions come so fast that they seem like a succession of dissolving views. Although all parts of it have been brought up to the latest dates, the chief alteration in the present volume, compared with its predecessor, is the adaptation to the Pharmacopœia of 1880.

INSANITY CONSIDERED IN ITS MEDICO-LEGAL RELATIONS. By T. R. BUCKHAM, A.M., M.D. Philadelphia, J. B. Lippincott & Co., 1883.

This rather odd and interesting book opens with an introductory chapter which is very consoling to the medical man who has been berated by some legal opponent, because it shows what a chaotic mass of contradictions and foolishness is the law, as enunciated from the lips of its judges. This Introduction portrays, indeed, the failure of the pure psychical theory of insanity, but is also largely composed of pithy condensations of judicial opinions, which are given more fully and with full references in the Appendix.

Chapters ii., iii., and iv. are respectively devoted to the discussion of—first, the “physical media” theory,—*i.e.*, the theory that the mind is an incorporeal or distinct essence working through a physical medium the brain, and that insanity is due to disorder of this instrument; second, the “somatic or materialistic” theory, that thought is a brain-secretion; third, the “intermediate” theory of Wharton and Stillé. We agree with Dr. Buckham that the exact nature of the latter theory—the exact meaning of Wharton and Stillé—is hard to make out; but either Dr. Buckham or ourselves have failed to grasp it, for his many pages seem to us not exactly to the point.

We must confess to weariness and distaste for these discussions, which must always end, to our thinking, where they start, because they are concerning that which is beyond the limits of human science. If a man's nature, education, belief, or what not, make him a materialist, he will believe in the somatic theory of mind, whereas if he start from a Christian stand-point he will believe in some form the physical media theory. The practical outcome is merely that we can know mind only through matter, and that an insane man is one with a perverted brain.

The early part of the fifth chapter of the book ought to be read aloud by the crier in every criminal and civil court in the land, and committed in extracts to memory by every Governor: then might we hope to see expert testimony less farcical than it now is. The following extract will show the drift of this chapter:

“Judges ought to know, lawyers ought to know, and the public ought to know that general medical practitioners, however able and

deserving of confidence they may be as such, are not experts in insanity; that no amount of general will compensate for the want of special knowledge; that they know no more respecting insanity than any equally well educated person outside the profession of medicine, and to the practice of using such physicians as experts is due largely the disgraceful character of the verdicts in every trial in which insanity is an element.”

In America there is always a tendency to worship the man whose work is palpable, and the surgeon has blood, legs, arms, and what not, to show for his labor, so that he is glorified by the crowd. It would perhaps be too much to expect the average surgeon not to share the popular prejudice as to his own superiority, but we once did hear a *great* surgeon say in court that because he was a surgeon therefore was he not a neurologist. Most numerous are, however, the little surgeons: so now, when in this city an insane commission is to be appointed, or an opinion to be delivered as to mental capacity, to the front goes the man of the dissecting-room and the surgical ward, and the hewer of flesh essays to be the gauger of intellect.

The latter portions of the fourth chapter are occupied with an elaborate and very able discussion of the question whether the expert or the judge should decide the question as to the sanity or insanity. It is clearly shown that common sense lays the responsibility upon the expert, but it is equally apparent, especially from the pages of Wharton and Stillé, as reproduced in the foot-notes, that under our present system of trial it would not be proper to take away the power and responsibility from the judges. We agree with our author that our whole system of trial is an abomination and ought to be reformed. Whether or not the elaborate scheme he suggests would be practicable, this is scarcely the place to discuss.

H. C. W.

ARCHIVES OF OPHTHALMOLOGY. Edited by Dr. H. KNAPP, of New York, and Dr. C. SCHWEIGGER, of Berlin. Vol. XII., Nos. 3 and 4. New York, G. P. Putnam's Sons, 1883.

Numbers 3 and 4 of this well-known journal appear in one publication, completing vol. xii. Thirteen original articles are contributed, the last one being the usual ophthalmic summary so essential to all who wish to keep pace with the progress of ophthalmology. The remaining articles may be thus classified: 1. Brief ophthalmic studies: (a) On the Representations of the Limits of the Visual Field, by Hilbert, of Königsberg. This paper has reference to the imperfect representations of the visual field afforded by the ordinary perimetric chart, and offers formulæ by means of which the latter may be transformed into a field such as would be obtained by the ordinary black-board. (b) The Focal Line in Astigmatism.

In this paper Dr. Swan Burnett calls attention to the error of applying the term focal plane to a plane supposed to pass through a focal line of an astigmatic system, and develops the distinction which exists between corneal astigmatism and the astigmatism of a system composed of a spherical and cylindrical lens. (c) Interchange of Liquids within the Eye, as shown by Injections of Fluoresceine, by Ulrich, of Strasburg. Dr. Ulrich contributes the results of some additional investigation with fluoresceine, and offers an explanation of the formation of the vertical line of Ehrlich. 2. Reports of Cases: (a) Tubercular Tumor of Choroid, by Swan Burnett, M.D. The removal of the eyeball in this case was followed by induration and softening in front of the ear of the same side, induration of the cervical lymphatics, ulceration of the conjunctiva, death apparently from phthisis. Drawings showing a longitudinal section of the eyeball and the microscopic appearances illustrate the paper. (b) Wound of Eye by a Cross-Gun Missile, by Webster, of New York. In this case there was found a cystoid cavity in the iris. (c) Eye Symptoms of a Case of Glioma Sarcoma in the Left Occipital Lobe, by Tany, of Breslau. Dr. Tany is inclined to refer the defect of the visual fields in this case to the lesion of the cortex of the left occipital lobe; it seems to us that he lays too much stress on this defect in his paper, as it cannot be regarded as a pure instance of right hemianopia. (d) Ectopia of the Eyeball induced by Orbital Osteophytes, by Birnbacher, of Grätz. This is a rare case, well reported. (e) An Anomaly of the Optic Nerve, by Purtschen, of Klagenfurth. This anomaly consists in an elevation of a sector of the optic nerve. We suppose all careful observers have recognized this anomaly. 3. Elaborate clinical studies: These are The Eye-Disturbances in Tabes Dorsalis, by Schmeichler, The Relations between Cerebral and Ocular Disease, by Nieden, Ocular Lesions after Injuries of the Brain and Spinal Marrow, by Nieden, Neurasthenia, by Wilbrand, of Hamburg. We hope to give abstracts of these papers in the next ophthalmic report, and defer critical notice of them for the present. All the articles referred to in this notice will be read with interest, and we commend those under the third heading to the attention of those practitioners who are accustomed to employ the ophthalmoscope as an aid in the diagnosis of disease. H.

A MANUAL OF PRACTICAL HYGIENE. By EDMUND A. PARKES, M.D., F.R.S. Edited by F. S. B. F. DE CHAUMONT, M.D., F.R.S. Sixth Edition, with an Appendix by F. N. OWEN. Vol. I. New York, William Wood & Co.

This new edition comes to us in the form of the September number of Wood's Medical Library. The work has been so long and so favorably known that but little is left to critics

but to repeat the encomiums which have been bestowed upon previous editions. The public interest in questions of preventive medicine is undoubtedly rapidly increasing: all departments of the science are being placed on a scientific basis, and the right of the State to preserve the public health by measures as summary as those by which it preserves public morals is gradually being acknowledged. On every side we see the tendency to appoint State Boards of Health, State chemists, and other official care-takers. We may regard this tendency as to a certain extent a reaction from the indifference with which public hygiene has long been regarded, and also a result of the recent developments in the theories of the origin and development of disease.

Under these circumstances the work of Parkes becomes especially valuable. Its author was a man of large practical experience and sound common sense. Every page of the work shows a disposition to avoid that sensational spirit which has been often displayed in the literature of hygiene. The first volume is devoted to the subject of water, air, food, and soils, principally considered in reference to civilian life; the discussion of military hygiene is deferred to the second volume. One hundred and eleven pages are devoted to water, and all the recognized methods of chemical and microscopical analysis are given. The preference is given, naturally, to Wanklyn's ammonia process, which has won of late years so much favor among water-analysts on account of its simplicity and the supposed trustworthiness of the data it affords. Very recent investigations have, however, somewhat altered its standing, and at the present time chemists may be said to be without any definite method of determining the potability of a water. The question is, indeed, largely an engineering problem.

In the department on food we notice that the sensible view is expressed that the butter-substitutes—*e.g.*, butterine—are not hurtful. A statement like this from high authority will go far towards upsetting the sensationalism which has been attached to this subject.

Concerning the topic of alcoholic beverages the language of the work is clear and positive, and the questions as to the effects of alcohol on the human system are discussed thoroughly. The array of facts presented leaves no doubt of the inadvisability of the use of even small quantities of alcohol as a part of our regular diet.

It is scarcely necessary to allude to the general fulness and accuracy of detail which characterizes all parts of the volume. It is a complete manual of hygiene, suitable both for student and for practitioner. Very few typographical errors occur. We notice a few: for instance, in Plate VI., Figure 1 should be 1'.

The general execution of the work is of good quality, the plates and cuts are well printed, and the type is clear. H. L.

GLEANINGS FROM EXCHANGES.

SUCCESSFUL RESECTION OF THE PYLORUS.

—The *Wiener Medicinische Wochenschrift* (Nos. 23 and 24) contains an account of a successful resection of the pylorus, and some observations on a gastroscopic symptom of cancer of the stomach, by Professor Mikulicz, of Cracow. The patient was a peasant, 25 years of age, the mother of three healthy children. Up to five months previously she had been in perfect health, but since that time had suffered from bad appetite, and discomfort and pain in the stomach occurring some hours after food. For the last three months she had, in addition, suffered from repeated vomiting. On admission to the Cracow Hospital, on February 9, 1883, her condition was as follows. Nutrition fairly good; skin and mucous membranes pale; both breasts swollen, red, and painful to pressure (the patient having only just weaned her last child), but not diseased; abdomen somewhat distended; abdominal walls thin; in the epigastric region a hard, apparently movable tumor, the size of a goose's egg, and painful to pressure, was made out. The stomach was considerably distended, its lower border reaching to three fingers' breadth below the navel. Bowels constipated; urine normal. The diagnosis of carcinomatous stricture of the pylorus was made. For the two days preceding the operation, which was performed on February 22, the patient had only fluid diet, and immediately before it the stomach was washed out with warm water. The operation was performed in the usual manner, and lasted two hours and a half. The tumor was freely movable. No spray was used, and iodoform dressing without drainage was employed. The portion removed measured three inches in length, and included, of course, the pyloric opening, which was found to be so narrowed that a little finger could scarcely be passed through it. Microscopic examination showed the growth to be a colloid cancer. An enlarged lymphatic gland removed at the same time showed no trace of cancer-elements. There was very little shock after the operation, the pulse the same evening being 72, and the temperature 98.5°. On the evening of the second day the patient vomited twice, and several times on the third, fourth, and fifth days; but on the sixth day the vomiting ceased. The vomited matter consisted each time of mucus without any admixture of bile. The pulse and temperature remained normal throughout, except on the fifth day, when the temperature reached 103.5° and the pulse 112, and on the evening of that day the patient had an offensive diarrhœa. During the first five days she took cold water by the mouth, and was fed by the rectum with peptonized enemata. On the sixth day she had soup and eggs, and on the eighth solid food. On the twentieth day the dimensions of the

stomach were normal, and the patient suffered from no gastric troubles. On March 22, the twenty-eighth day after the operation, she left the hospital in good health.

From a consideration of the absence of all signs of peritonitis in the case, from the course which the wound took, healing by first intention, from the considerable dilatation of the stomach that existed from the third to the fifth day, and from the character of the vomited matter, Mikulicz considers that the vomiting was due to a complete but temporary obstruction of the new pyloric orifice. The cause of the obstruction he thinks might have been due to an inflammatory swelling of the wound at the pylorus, or the dilatation of the stomach and the weakness of its walls might be insufficient to propel the contents through the new orifice. According to Mikulicz, thirty-two cases of resection of the pylorus have been published, of which twenty-four ended fatally and eight recovered. Of the eight successful cases, two were operated upon for ulcer of the stomach, and six for cancer. Of the twenty-four unsuccessful cases, twenty-three were for cancer, and one for ulcer. In twenty-one of the twenty-four fatal cases the cause of death is given. Fifteen died of collapse, one of inanition, and five of peritonitis,—the peritonitis in two cases being due to perforation at the seat of union, and in two cases to gangrene of the transverse colon. These four fatal cases of peritonitis, and the case of inanition, were due to causes which at the present time might be avoided. The large number of cases which died of collapse, Mikulicz considers with Billroth to be due to the general marasmic condition of the patients, and to the severity of the operation in those cases where the tumor was large and had formed adhesions to neighboring parts. Only cases where the patient is well nourished, and the tumor of moderate size and movable, are, he considers, suitable for operation. The future of resection of the pylorus depends, he holds, on improvement in the diagnosis of cancer of the stomach at an early stage, and he looks to the general use of the "gastroscope" as likely to afford valuable aid in that direction. In a large number of cases of cancer of the stomach examined by him he has found certain appearances and symptoms which may be of use in diagnosis. In a healthy man, the pylorus, examined "gastroscopically," appears as a longitudinal, oval, or triangular slit, or as a circular opening surrounded by close, bright-red mucous projections and folds. Owing to the irritation caused by the instrument and to the inflation, the opening is continually changing its shape, and the folds moving with each contraction of the muscular wall. The fundus of the stomach, on the contrary, remains stationary. In cases of cancer of the stomach he has noticed that the coarse folds are either entirely wanting, the walls being quite smooth,

or are only slightly marked; and, secondly, that the movements are altogether wanting. Also in certain cases he has noticed considerable pallor of the pylorus; in others quite a dark cyanotic appearance. In one case the submucous veins were dilated, and of a deep-blue color. No ulceration of the cancerous mass has he ever seen. The explanation of these changes he considers to be that, the walls of the stomach being infiltrated by cancer, the movable organ is changed into a comparatively rigid tube, in which the formation of folds and the changes in shape cannot occur.—*Medical Times and Gazette*.

TWO CASES OF ABSINTHE-POISONING.—Dr. Albert S. Adler, of Lordsburg, New Mexico, writes, "A few nights ago I was called upon to attend two individuals who had been drinking heavily and were now in convulsions. Hastening to their place of abode, I found one of the patients, a woman, in an epileptiform convulsion,—unconscious, small pupils, and frequent and small pulse. The other was also unconscious, but not then in spasms. All questions in regard to poisoning were altogether refuted by the other inmates of the house. I was about to resort to some stronger means in order to relieve their sufferings, when the young girl, returning suddenly to complete consciousness, claimed that she and her male friend had partaken of over a quart of some alcoholic liquor, the principal part of which was absinthium. The epileptic convulsions had commenced half an hour prior to my arrival, and, as before stated, lasted in the girl but a short time during my presence: they had been more vehement and frequent in her, because she had taken a larger quantity. The man was restored to his senses by slapping his face with wet towels. These cases of epilepsy are of more frequent occurrence than generally supposed. Magnan ('De l'alcoolisme, des divers formes du délire alcoolique,' etc., Paris, 1874, and *Annal. Méd. Psych.*, 1874, page 302) was the first to describe the danger of absinthe-drinking. His experiments on animals, as well as observations on man, have demonstrated that it was not the alcohol which brought forth the spasms, but that the absinthium was the source of the vehement symptoms. Alcohol occasions delirium and tremor, absinthium these two and epilepsy in acute alcoholism. Small doses of wormwood given to animals have the effect of producing tremor of the muscular system, dizziness, and in a surprising manner upstarts of individual muscles, in larger doses a completely-formed epilepsy. In man, besides the alcoholic delirium, epilepsy is noticed. Among three hundred and seventy-seven persons addicted to the use of alcohol, Magnan found, in 1870, but thirty-one epileptic cases, and in 1871, among two hundred and ninety-one, only fifteen. In France it is regarded by the legal authorities as a poison, and only allowed to be sold in drug-

shops. Magnan comes to the conclusion that if epileptic attacks happen in acute alcoholic poisoning, it was only in absinthe-drinkers, and that acute alcoholism without epilepsy, but with tremor of any degree, was seen only in persons partaking freely of wine or whiskey."—*Medical Record*.

LYMPHO-SARCOMA.—A number of specimens illustrating a malignant form of Hodgkin's disease were exhibited by Dr. Carrington at a recent meeting of the Pathological Society of London. The patient, a woman, aged 55, had died in Guy's Hospital under the care of Dr. Goodhart. She stated that she had first noticed swelling of the glands on the left side of the neck in June, 1882; in August following, the legs and abdomen became swollen. When admitted, on February 7, 1883, she was very anæmic and emaciated, and the subcutaneous tissues were generally œdematous; the cervical, submaxillary, axillary, and inguinal glands were enlarged; the spleen was very large, reaching as low as the crista ili. An examination of the blood showed that there were about 4,720,000 red corpuscles to the cubic millimetre, and about 4.3 white corpuscles to every thousand red corpuscles. A week after her admission she was seized with palpitation; there was no fever, but the urine was found to contain a trace of albumen, and the patient died the same day. At the post-mortem examination, in addition to the great enlargement of the superficial glands noted during life, the mediastinal glands were found to be enormously enlarged, extending along the bronchi into the lung, but not involving the pulmonary tissues. The stomach was studded, on its mucous surface, with numerous cream-like flattened tumors; the pyloric orifice was involved, but the duodenum was free from disease. The valvulæ conniventes of the small intestine below the duodenum began to show disease, being firmer than natural, and swollen; lower down they became polypoid and creamy. The solitary glands and Peyer's patches were enormously swollen; the cæcum contained a mass of growth that weighed half a pound; the spleen, though greatly enlarged, and weighing forty-four ounces, retained its natural form, and it was everywhere permeated by a soft new growth. Microscopic examination of the growth showed it to be of a lymphomatous nature. Dr. Carrington had been able to find only four similar cases recorded in the Transactions of the Society. The president considered the case to be of great interest; he had never seen a similar one. Dr. Pye Smith referred to a case of this kind recorded by Dr. Behier about twenty years ago, which was, he believed, the earliest on record; it was a case of lymphatic overgrowth of the lymphatic structures of the intestinal canal. Dr. Sydney Coupland observed that an instance of this disease had

been preserved by Cruveilhier in his Atlas; it was probably the earliest case of which any note remained.—*British Medical Journal*.

HAMMOND ON SPASMODIC STRICTURE.—Referring to the peculiar condition which Sir James Paget has called stammering of the bladder, Dr. Wm. A. Hammond gives an interesting reminiscence. He says,—

"It is undoubtedly due to a spasm of the organic muscular fibres of the urethra and of the compressor urethræ muscle. It is exactly similar to the condition sometimes excited in nervous individuals by attempts to pass a bougie. The canal closes tightly against the point of the instrument, but a steady gentle pressure continued for a few minutes usually overcomes the obstruction. The remarkable fact, one which all physicians and surgeons have observed, is that the condition should be excited by mental influences and certain associations of ideas. I have known men who could not urinate when asked to do so, unless the water above the urinal were allowed to run at the same time, so that the idea of a flowing stream should be excited in their minds. The fact is common enough, and it is one well known to people generally. I recollect when a college boy being witness to a wager between two men that one of them could not urinate in the other's hat. A ring of curious spectators was formed around the individual desirous of exhibiting his powers of urination; he had a full bladder, he said; he prepared himself, held the hat of his adversary in his hand, but not a drop would come, and the more the lookers-on laughed and cheered, and the more he strained, the less real ability he seemed to exhibit. At last the referee announced that the time, a half an hour, was up, and he lost his bet without having passed a single drop. Five minutes afterwards, in the solitude of a woody lane, he evacuated over a pint."—*New York Medical Gazette*.

ERYTHRASMA.—In his service at the Hospital St. Louis, Dr. Ernest Besnier showed a patient affected with a disease little known and yet somewhat frequent, and which may easily give rise to errors in interpreting it. It consists of spots having the appearance of intertrigo, but presenting a certain amount of pigmentation. The spots are more or less rounded, or in the form of disks, and occupy at times quite an extensive surface. They are seated in the axillæ, groins, scrotum, and chiefly at all those points where intertrigo occurs. In those parts which are outside of folds they present a pale-red color, which has given the disease its name,—erythrasma. There is but little itching, without intense reaction, and it is on this account that it is seldom observed, the patients not attaching sufficient importance to it to occupy themselves about it. The author considers it a parasitic disease, whose

parasite, of an extraordinary tenuity, can only be observed by means of an objective by immersion, and called *Microsporon minutissimum*. Histological examination shows that in the horny layer of the epidermis there is contained a very large number of these cryptogamic elements. The coloration of the spots is due not only to the extreme abundance of the parasite which infiltrates this layer, but also to the presence of pigment-granules mixed with spores, which is the result of cutaneous irritation, and of chronic pruritus also. The affection is not a grave one, yet it is important to recognize it, and not to mistake it for pityriasis versicolor, to which it bears some similarity.—*Medical Review*.

PROLONGED SUSPENSION OF VITALITY FOLLOWING THE HYPODERMIC INJECTION OF MORPHIA AND ATROPIA.—A woman, 37 years of age, upon whom an operation had been performed for the removal of the left ovary, at noon, four days after the operation, became very excited and disturbed the dressings of the wound, when twelve minims of the hospital solution of morphia and atropine were injected. This represented three-fifths of a grain of morphia and one-fortieth of a grain of atropine. At one o'clock she became livid, and the nurse by mistake injected another five minims of the solution before the house-surgeon arrived. When he came, he injected ammonia, gave brandy enemata, used artificial respiration, and applied electricity, without effect. At 4 P.M. the nurse was laying the woman out, but the doctor came in and determined to proceed with artificial respiration, galvanism, and frictions. Up to 5.30 P.M. only a spasmodic breath every quarter of an hour, and a feeble beat of the pulse every now and then, could be detected. At 7 P.M. a nurse poured some coffee into the patient's mouth, and she suddenly fell back as if dead, but by turning her over on her side she was made to vomit. By nine o'clock the respirations were beginning to be more frequent and the pulse stronger; she soon became conscious after this, and recovered perfectly.—Dr. Alexander, in the *Boston Medical and Surgical Journal*.

TRANSIENT ANÆSTHESIA WITH BROMIDE OF ETHYL FOR MINOR OPERATIONS.—Dr. A. E. Prince, of Jacksonville, Illinois, recommends ethyl bromide, not as a substitute for chloroform and ether, but for its primary effect, it having a period of primary anæsthesia extending from fifteen seconds to two minutes. This makes it of special value for short operations, such as pulling teeth, opening a felon, stretching the sphincter ani, or for diagnosis, and, if the effect is desired to be continued, chloroform or ether may be used. It is as a substitute for nitrous oxide gas that he especially prizes the ethyl bromide.—*St. Louis Medical and Surgical Journal*, October, 1883.

LOCOMOTOR ATAXY NOT TABES DORSALIS.—Matters seem to have rapidly reached a height towards which they have for some time been tending. Before recent years it was something to know that locomotor ataxy was associated with, if not caused by, posterior sclerosis. A fresh and important step in advance, for which we are indebted to Pierret, was made when that able observer declared that the only region sclerosis of which was necessary for the production of the signs of locomotor ataxy was the postero-external column, or "root-zone" of Charcot. Many clinical investigators have shown that the most characteristic symptom of "tabes dorsalis" may be long or even altogether absent,—that the awkward gait might never make its appearance. Coetaneously with the propagation of these doctrines,—by Buzzard, Gowers, and others,—Pierret, and afterwards Déjérine, were upholding the doctrine that most, if not all, the symptoms of "tabes dorsalis" might be due to multiple peripheral neuritis. In a partially successful case of nerve-stretching for locomotor ataxy by Langenbuch, the patient died at a second operation, apparently from the administration of chloroform. It was found that no changes existed in the spinal cord. Though the peripheral nerves do not seem to have been examined, the instance is of importance in the light of the latest researches of Déjérine. Disturbances of sensation and disorders of locomotion, apparently absolutely identical with the signs of classical tabes dorsalis, have now (*La France Médicale*, October 30) conclusively been shown to have existed in two cases in which the spinal cord, spinal roots and ganglia were perfectly healthy, but in which the peripheral nerves exhibited the changes ascribed to atrophic parenchymatous neuritis.—*Lancet*.

MISCELLANY.

A STRANGE BEQUEST.—*The Medical Press* details the sad circumstances attending the death of M. I. Khan, M.R.C.S., of University College Hospital, who committed suicide by taking poison. The deceased was an Afghan, who, after successfully pursuing medical studies in England, and obtaining a double qualification, found his color and nationality a bar to obtaining employment there, and, growing discouraged by disappointment, and being without resources, he at length put an end to his life. In a letter addressed to the coroner Mr. Khan expounds his views as to suicide, which he justifies in himself; and then makes a strange bequest of his body for dissection at University College, a request being added that his skeleton shall be preserved in the museum.

The story is a very sad one, and if, as is said to be the case, the offer of the deceased is accepted by University College, his skeleton will be not the least interesting object in the collection.

BENZOPHENID.—In a recent trade report Messrs. Gehe state that they have taken an opportunity, while saturating a large quantity of benzoic acid sublimed from resin, to isolate the adherent body, upon the presence of which depends the brown color that is now one of the official characters of benzoic acid in the German Pharmacopœia. It is believed to be "benzophenid," and when treated with alkalis breaks up into benzoic acid and phenol (*Pharmaceutical Journal*, September 29). Some physiological experiments made with the substance by Dr. Robert, of Strasburg, seemed to show, however, that a similar decomposition does not take place in the body when benzophenid is administered internally; at least, no increase of phenol has been detected in the urine; in this behavior it resembles chloral hydrate, which does not yield chloroform. Rabbits did not appear to be affected by it when administered in doses of ten grammes, and an alcoholic solution injected under the skin of a frog produced no perceptible symptoms.—*Lancet*.

FATAL HEMORRHAGE FOLLOWING EXTRACTION OF A TOOTH.—A young man, 26 years of age, of English birth, had the right superior second molar tooth extracted on account of its badly-decayed condition. Constant oozing from the socket followed, and the patient died on the eighth day. He had had teeth drawn previously without serious hemorrhage. The family history showed a marked hemorrhagic diathesis, confined to male members, his father, two uncles, and a cousin having died of hemorrhages from wounds. The patient refused medical or surgical treatment on conscientious grounds, as he was of the Mormon faith, or his life might have been saved.—*The Dental Cosmos*, November.

SUPPRESSION OF QUACKERY.—At the annual meeting of the New York County Medical Society, held October 22, the sum of three thousand five hundred dollars was appropriated for use during the ensuing year in prosecuting illegal practitioners. The report of the proceedings of last year showed that the proper officers of the Society had performed their unwelcome and often disagreeable task with satisfaction, and had found, with few exceptions, that they had the co-operation of the court in carrying out the law.

SALICYLIC ACID PASTE IN ECZEMA.—

℞ Acidi salicylici, gr. x;
Petroleol., ℥iv;
Pulv. zinci oxidi,
Pulv. amyli, āā ℥ij. M.

Rub up into a smooth paste.

VAN HARLINGEN.

GOOD ADVICE, BY THE EDITOR OF *The Planet*.—Life may be taken away at any moment, even while we are sitting in our room, where we would think death could not possibly reach us. Property may be lost by fire, insurance only partially remunerating us; but as regards money, good management evidently may save from ruin; but how many people conceive what constitutes good management? Speculation and extravagance in living are our two pursuing devils, who are ever seeking for whom they can devour.

If we are to remain with our confrères and live, let us attend to our church duties, to rules of hygiene and temperance, let us curb our tempers, try to be agreeable towards everybody, bring up the family in decency and propriety, and, lastly, avoid extravagance.—*The Planet*, November 15.

NOTES AND QUERIES.

THE BALTIMORE CORRESPONDENT'S ANSWER.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

SIR,—I have just returned to this city, after a month's absence, and find, on looking over late numbers of the *Times*, that my letter on "Medical Education in Baltimore" has given great offence in a certain quarter. Had Drs. Monroe and Byrd, in replying to my strictures on the methods of the Baltimore Medical College, confined themselves to correcting alleged misrepresentations, the necessity for writing this letter would not have arisen; for the article in the Educational Number of the *Times* contained no misrepresentations.

In the letters of Drs. Monroe and Byrd, however (*Times*, November 3, p. 118), appear several statements which demand my attention, inasmuch as they call in question my veracity and reliability as a correspondent of such a reputable journal as the *Times*, and hence I ask sufficient space to place the institution defended with such wealth of quotation and lavish display of italics by Dr. Byrd in its proper light.

Dr. Monroe says the Baltimore Medical College was organized to graduate a superior class of doctors,—to quote the words of the catalogue, "Not to make many doctors, but good and competent ones;"—and then goes on to enumerate the methods by which this result shall be attained.

In this connection, I would merely remark that certain circumstances which have come to my knowledge have convinced me that they have not met with any marked degree of success in carrying out their high ambition.

Dr. Byrd objects to my statement that the members of the faculty of this institution "should likewise be professors of Christianity." He says that the charter "requires that all its professors and teachers shall declare their belief in the Christian religion ere entering upon their respective duties." I can really see no difference in meaning between the two versions, except that mine seems the clearer statement.

Drs. Monroe and Byrd both deny that the establishment of a pulpit was contemplated. My information was derived from the only morning paper here which thought it matter of sufficient interest to notice the last introductory exercises. The report, so far as I was aware, had not been contradicted.

And now, with reference to the number of graduates of the Baltimore Medical College practising in West Virginia. Drs. Monroe and Byrd both know—in spite of their assertion to the contrary—that only one of the graduates of this school is practising in that State by warrant of law, and he not by virtue of his diploma. If any other graduates of the Baltimore Medical College are practising medicine in that State, they are doing so surreptitiously and in defiance of the law. Drs. Monroe and Byrd know these facts as well as I do.

Dr. Byrd accuses me of "absolute falsehood;" I have shown that my statements were but the exact truth. I can assure Dr. Byrd that denouncing a statement as untrue does not make it so; and, if he will accept a little advice from me, I would suggest to him to be sure of his own facts before he again undertakes to question the accuracy of those of

GEORGE H. ROHÉ.

BALTIMORE, November 24, 1883.

RESOLUTIONS UPON THE DEATH OF DR. J. MARION SIMS.

"At a called meeting of the Faculty of the Baltimore Medical College, held on the 27th of November ultimo, the following preamble and resolutions were offered by Prof. Harvey L. Byrd, and adopted unanimously,—viz.:

"Whereas, We have learned with profound sorrow and deep regret of the death of Dr. James Marion Sims, which sad event occurred in New York City on the 13th instant;

"And whereas, It behooves us as a corporation and as individuals to bear testimony to his brilliant career and great achievements, which have enriched the profession of medicine so much, especially in the knowledge and skill he so successfully applied for the relief of suffering womankind; be it, therefore,

"Resolved, That we deplore the decree of our Heavenly Father which called from the midst of the living James Marion Sims, and from the profession which he so much honored, and thus stilled forever the cunning hand that had wrought relief to so many suffering women in both hemispheres.

"Resolved, That these proceedings be spread upon the minutes of this meeting, and that a blank page of the records of this corporation be inscribed with his name and the dates of his birth and death; and that a copy of the foregoing be forwarded to his bereaved family, with the assurance of our sincere sympathy and condolence in their irreparable loss.

"Resolved, That the editors of the *Medical Record* and the *Philadelphia Medical Times* be respectfully requested to publish the same."

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM NOVEMBER 24 TO DECEMBER 8, 1883.

WOLVERTON, WILLIAM D., MAJOR AND SURGEON.—Assigned to duty as post surgeon at Washington Barracks, D.C. Paragraph 7, S. O. 222, Department of the East, November 27, 1883.

BROWN, PAUL R., CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty in the Department of Arizona. Paragraph 4, S. O. 273, A. G. O., November 28, 1883.

CARTER, W. F., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty at Washington Barracks, D.C., to take effect at the expiration of his present leave of absence, and assigned to duty at Little Rock Barracks, Arkansas. Paragraph 4, S. O. 224, Department of the East, November 30, 1883.

MERRILL, JAMES C., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty in the Department of the East, and assigned to duty at Columbus Barracks, Ohio. Paragraph 4, S. O. 270, A. G. O., November 24, 1883.

SHUFELDT, R. W., CAPTAIN AND ASSISTANT-SURGEON.—Now on sick-leave, relieved from duty at Jackson Barracks, New Orleans, Louisiana. Paragraph 3, S. O. 224, Department of the East, November 30, 1883.

BREWSTER, WILLIAM B., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Extension of leave of absence granted September 15, 1883, further extended two months. Paragraph 4, S. O. 271, A. G. O., November 26, 1883.

MADDOX, THOMAS J. C., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Granted leave of absence for two months. S. O. 136, Department of the Missouri, November 24, 1883.

RICHARD, CHARLES, FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to duty at Jackson Barracks, New Orleans, Louisiana. Paragraph 2, S. O. 224, Department of the East, November 30, 1883.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY FROM NOVEMBER 24 TO DECEMBER 8, 1883.

Medical Inspector D. KINDLEBERGER to be relieved from duty on the Retiring Board on December 9.

Medical Inspector D. KINDLEBERGER ordered to the U.S. steam-ship "Hartford," Pacific Station, per steamer of the 10th inst.

Medical Director A. L. GHON detached from duty as member of Board of Inspection and Survey on the 15th inst., and placed on waiting orders.

Medical Director GEORGE PECK ordered to report on the 15th inst. as member of the Board of Inspection and Survey.

CLINICAL LECTURE

ON REMOVAL OF THE OVARIES FOR MENORRHAGIA—OÖPHO- RECTOMY FOR CONFIRMED MAS- TURBATION—OVARİOTOMY FOL- LOWED BY ABSCESS IN THE ABDOMINAL WALL—CRIMINAL ABORTION—PROLAPSE OF THE UTERUS WITH PROLAPSE OF ONE OVARY.

Delivered at the Hospital of the University of Pennsylvania, October 3, 1883,

BY WILLIAM GOODELL, M.D.,

Professor of Gynecology in the University of Pennsylvania.

Reported by WILLIAM H. MORRISON, M.D.

REMOVAL OF THE OVARIES FOR MENORRHAGIA.

GENTLEMEN,—This patient has suffered from excessive menorrhagia and from severe ovarian pains and aches. She had been attended by many physicians, and at last she came to me to see what I could do for her. I tried various modes of treatment, but with very little benefit. I finally removed the ovaries, eleven days ago; and I bring the patient before you to-day that you may see her condition. She was very much reduced in strength before the operation, but she has not had a single bad symptom. The great majority of these cases that I see are so worn out that they are nothing but skin and bone, and they have not the resiliency and strength to endure the operation as they would have if not quite so much reduced. Yet I prefer a certain amount of emaciation, for then the opening in the abdominal wall is not so deep.

I now show you the wound at the end of eleven days. The operation was done with every antiseptic precaution. It was done under the spray; the instruments were immersed in a solution of carbolic acid, the sponges in the same, and every effort was made to obtain cleanliness in all respects. The gentlemen who assisted me had on clean clothing, and had washed themselves very carefully. I make it a point, although I take a bath every morning, to take a soap-bath on the morning that I am going to perform an ovariectomy. This wound has been dressed with gauze which had

been kept for weeks in a solution of one part of crystallized carbolic acid to seven parts of glycerin. The gauze was laid directly on the wound, and over it was placed a pad of cotton which had been baked in the oven; this was secured by a flannel binder. The result has been perfect union.

The operation which was performed in this case was oöphorectomy, which literally means removal of the ovary. It is precisely the same as ovariectomy, but oöphorectomy has been restricted to the removal of ovaries which may or may not have any intrinsic disease, but which are extirpated in order to arrest menstruation. Ovariectomy is limited to the removal of ovaries which are diseased and usually much enlarged. The former operation has also been termed normal ovariectomy,—that is, removal of the normal ovaries for a specific purpose. In this case I did not remove the ovaries because they were diseased, but for the purpose of bringing on the change of life, which in the majority of cases it does. Occasionally menstruation persists after the removal of both ovaries. This is explained on the supposition that in these cases there has been a third ovary, or that all of the ovarian tissue has not been removed, a result which is likely to occur with inexperienced operators.

When do we perform oöphorectomy? It is often employed in pernicious menstruation, which is a generic term covering a great deal. If there is a fibroid tumor of the womb producing an excessive menstrual flow which cannot be checked, we would call such a condition pernicious menstruation. Sometimes epilepsy occurs at the menstrual period, or just before the period; the woman will have hallucinations, or there may be ovarian insanity. These come under the same label of pernicious menstruation. At other times the woman is bedridden, suffering severe pain from the congestion and enlargement of the ovaries. This is another example of the same condition. By the removal of the ovaries relief from these symptoms is in the great majority of cases secured. The operation is still young, and, I think, has been abused, and is in danger of being abused. It requires the utmost caution on the part of the surgeon to decide whether or not to remove the ovaries. The extirpation of these organs does not unsex the

woman in regard to her appearance, to her feelings, or to her place in society; it simply prevents her from having children. There are several cases reported in which both ovaries have been removed by careful surgeons, and yet the woman has, months or years afterwards, given birth to a child. This has most likely been due to the presence of a third ovary, together with its Fallopian tube. I have never met with such a case, but there are numerous instances in which a third ovary or ovarian structure has been found in the broad ligament, apart from the two ovaries.

REMOVAL OF THE OVARIES FOR CONFIRMED MASTURBATION.

Three weeks ago I had this patient before you, and told you before she came in what a sufferer she had been, and told you that I should perform oöphorectomy. The operation was done eighteen days ago. In this patient there was considerable fat, so that, in order to obtain a sufficient opening, the incision had to be extended high up. On the other hand, I do not like to have the patients too thin, because loss of flesh means loss of vital power, and such women are not so likely to survive the operation. There has been since the operation an amelioration of the symptoms, and I think that she will continue to improve. Since last May it has been necessary to employ a catheter. I think that in time she will regain control over her bladder, and this difficulty will be overcome. It is a nerve-symptom, and is due to contraction of the muscular fibres surrounding the urethra.

The operation of oöphorectomy is performed in the following manner: The spray-producer is set about six feet from the patient and the spray directed over the wound, not so as to drop into the wound, but so as to go directly over it and carry away or destroy any germs that may fall from the air. The instruments are placed in a tin pan and covered with a five-per-cent. solution of carbolic acid. Just before the operation, hot water is added, reducing the strength of the solution to two and a half per cent. The sponges are put into a warm solution of the latter strength. The incision is made in the linea alba with considerable boldness until the peritoneum is reached. It is recognized by the overlying fat. All bleeding points are caught with pressure-forceps, and there may be a dozen of these dangling from the wound at one time.

The rule is to stop all bleeding before the peritoneum is opened. A great deal of caution must be exercised in opening the peritoneal cavity. This operation is more difficult than ovariectomy, for the intestines are immediately under the wound. If an intestine were glued to the peritoneum, it might readily be opened. This accident has repeatedly happened. Almost all the gentlemen who perform oöphorectomy have opened the intestine. So far I have not had this accident occur. I open the abdominal cavity in this way: When I get to the peritoneum, which I recognize by its blueness, thinness, and tendency to bulge into the wound, I catch hold of it with a tenaculum. I take a very superficial hold of it, raise it up, and, cutting laterally, make a little nick on one side. In this way I make a minute opening and can see whether or not I am in the abdominal cavity. I then enlarge the opening with a director and scissors, or, as I consider the better way, introduce a finger and cut on it. Having done this, two fingers are passed in, and the position of the fundus of the womb is determined. The fingers, one on each side of the broad ligament, are then passed down, and the ovary is caught between them and brought far enough up to be grasped with the forceps. Sometimes the ovary eludes the fingers; it then has to be caught with the fenestrated polypus forceps. The ovary having been brought to the external wound, the broad ligament is transfixed with a double thread low down, and ligatured on each side. Then the ends of one ligature are brought entirely around the stump and again tied. The stump is caught with a small pair of forceps and the ovary removed. The pedicle is next examined, to see if it is sufficiently long, and whether there is likely to be any bleeding. The same thing is done with the other ovary. I usually pass a sponge into the cavity of the abdomen, to catch any blood that may escape. The ovaries being removed, a small sponge, held by forceps, is passed into Douglas's cul-de-sac, to remove any blood that may be there. In closing the abdominal wound, threads eighteen inches long, armed at each end with a needle, are used. These are kept in a five-per-cent. carbolic acid solution. They are passed from within outwards. This is done for three reasons: 1, if passed from the outside and the patient should happen to cough, the intestine

may be wounded; 2, if the needle become blunted, it may strip off the peritoneum without penetrating it; and, 3, as the peritoneal is the vulnerable surface, it is desirable to have the stitches placed there as neatly as possible. The needles are passed about one-fourth of an inch from the edge of the peritoneum, and about the same distance from the edge of the skin. The mistake which beginners make is to include too much skin. I used to include half an inch. If this is done, the edges do not come into close coaptation, but pucker. While the stitches are being inserted, a sponge is kept in the abdominal cavity, directly under the incision, to prevent blood from getting into the cavity. When all the stitches are in position, the ends on one side are brought together, twisted into a cord, and grasped with forceps. The same thing is done on the opposite side. One finger of each hand is placed in the wound, and the sutures separated. A careful examination is then made to see whether or not there is any collection of blood in Douglas's pouch. All sponges are then removed, and the edges are brought together by pressure, in order to chase out the air, and the sutures are rapidly tied. After tying, the ligatures are cut off, leaving ends an inch and a half long. The wound is dressed with carbolic acid and glycerin, as before described.

The after-treatment consists in giving no food for twenty-four hours. Milk in tablespoonful doses is then cautiously allowed. I tell the patient that if she feels inclined to break wind she is not to restrain herself on account of the presence of any one in the room. The escape of wind from the anus is, in these cases, a most welcome sound. It indicates that the intestines are not paralyzed, that there is no peritonitis, and that there is to be no collection of air in the intestine. Tympanitis is in these patients a very distressing symptom, and sometimes requires the introduction of the catheter into the bowel. (The patient was now removed.)

This, gentleman, was the case of excessive masturbation which I showed you on a former occasion. I told you that to a certain extent the operation was an experiment. She has improved, and is now more calm and placid. I feel pretty sure that if I could have her under my direct control for a month I should cure her of

this habit. I shall watch the case with great interest, and shall report the result in a few weeks.

OVARIOTOMY, WITH ABSCESS OF THE ABDOMINAL WALL.

This third case is one of ovariectomy on which I operated three weeks ago. The wound has healed in every respect but one. This occasionally happens in spite of antiseptic precautions. I refer to the development of little abscesses along the suture-tracts. These heal up rapidly. I used to attribute their formation to the inclusion of the fibres of the recti muscles in the suture, but I do not now think that this is the true explanation. The abscesses are probably due to the bruising of the parts by the pressure-forceps. All of these cases have recovered without a bad symptom. This patient has lost considerable flesh, and, although only 48 years old, looks much older. These furrows about the forehead and lines about the eye are characteristic of the *facies ovariana*. In fibroid tumors this expression of countenance does not exist. There is usually then a brown discoloration of the skin. A woman with a fibroid tumor has also a tendency to become fat, or, at any rate, she is in pretty good condition, and does not emaciate like a case of ovarian tumor. Strange as it may seem, the loss of blood tends to the production of fat, but the fat is of a flabby kind. In some parts of Europe it is the custom of butchers to bleed the calves in order to render the veal white and fat.

In this patient, both ovaries were diseased, and were accordingly removed. Here is a point which is an indication that both ovaries were affected. She has, as you can see, considerable hair on her chin and upper lip. In women past the climacteric, whose ovaries are shrivelled and shrunk, a beard develops; but here is a comparatively young woman who should not have a beard. This is due to the condition of the ovaries.

I here show you the temperature-chart of this woman. The evening after the operation, the temperature was 98°; the next morning, 100.6°. It then continued normal until the abscess developed, when it ran up to 100°. The disturbance has not been as great as would ordinarily follow the amputation of the little finger. She was kept twenty-four hours without anything to eat. Sometimes I give nothing for thirty-six hours, except a little cracked

ice, and, if necessary, an occasional teaspoonful of good brandy or whiskey. She then received a tablespoonful of milk every two hours. The next day the quantity was increased to two tablespoonfuls, and the next day to three tablespoonfuls every two hours, the quantity being gradually increased. She has now an excellent appetite. The loss of flesh is due to the abstraction from the blood of the rich constituents of the fluid. I have known an ovarian cyst after being tapped to fill up at the rate of a pound a day, which meant the loss of nearly one pound of blood each day.

She is now taking strychnia, in the form which we term the "lemonade iron." It is prepared as follows:

R Strychninæ sulph., gr. $\frac{3}{4}$;
Tinct. ferri chloridi, ʒiv ;
Acidi phosphorici dil., ʒvi ;
Syrupi limonis, vel simp., q. s. ut ft.
 ʒvi . M.

Sig.—A dessert-spoonful after each meal.

This preparation of iron is very good for children. I give one minim for each year of age. Iron in a fluid form is, I think, more readily assimilated than when given in pills. The objection to the tincture is that it injures the teeth. The precaution should be taken to have the medicine well diluted and taken through a glass tube and the teeth well brushed with soda and water.

CRIMINAL ABORTION.

Before bringing in the next case, I want to tell you something that happened to me lately. I have often told you to be cautious in passing the sound, so as not to produce abortion. You will often be urged by unmarried and married women to bring on a miscarriage for them. I urge you not to accede to their wishes. I do this for two reasons: first, because it is a criminal act and a great sin before God and man; and, second, because you are liable to get into trouble. Years ago, I have had persons approach me in this way, but I thought the time for that had gone by. Night before last, a young woman came into my office and said she wished to see me. I told her that if she wanted an examination I could not make it then, but that she would have to come in the morning. She returned yesterday morning and told me that she had gone two months without seeing her monthlies, that she knew she was pregnant, and that she wanted

me there and then to bring on an abortion. I was very angry, and asked her who had sent her to me. She had heard that I treated female complaints, and thought that I would help her. I explained to her that it was a great sin. She admitted that, but said that she was going to have it done. So I bade her "good-morning."

PROLAPSE OF THE UTERUS WITH PROLAPSE OF ONE OVARY.

This is a patient that I have not seen before. She states that she is 28 years old, has been married nine years, and has had four children, the youngest of whom is two years old. She complains of severe bearing-down pain; she at times becomes very melancholy, has pains in the left side, and lifting tends to bring on the monthlies. I have an idea as to the nature of the trouble. I have seen analogous cases, and have frequently found two conditions,—retroversion of the uterus, and prolapse of the ovaries. In one case I slipped the ovary up and introduced a pessary, and the patient immediately improved and became brighter. In a short time the ovary fell down again, and she came back with a suicidal tendency. After the ovary was pushed up, she again got better, but now she is much worse; and it is a question whether or not it would not be best to remove the ovaries.

This patient says that she passes a great deal of water, and that it is of the color of spring-water. This would seem to indicate a nervous element. Examining per vaginam, I find a tear of the cervix and some enlargement of the glands of Naboth. There is no retroversion, the womb being in a good position of anteflexion. There is, however, prolapse of the anteflexed womb. The left ovary is prolapsed, but I cannot feel the right ovary. If I were to press on it and squeeze it, as I might a cherry-stone, between my fingers, it would slip away, and she would jump as though I had stabbed her with a knife. I was partly right and partly wrong in my supposition.

She has no retroversion, but the womb is prolapsed and presses upon the nerves. She also has prolapse of the ovary. The sound gives a measurement of three and a quarter inches. If the laceration were closed, the measurement would be at least three and a half inches. There is subinvolution, and I have no doubt that there are within the cavity fungous vegetations. She has a dislocated ovary, which is

larger than it should be. The congestion of the ovary has acted secondarily on the womb. As I have often said to you, the word "woman," or *womb-man*, is a misnomer. She is a woman because she has ovaries,—not because she has a womb. A woman who is born without ovaries remains a child and undergoes no development, while, on the other hand, many a woman is born without a womb and yet has all the development and attributes of womanhood. The scientific label of woman should be "ovary-man."

The congestion of the ovaries causes an interference with the circulation of other parts; the womb is enlarged and prolapsed, and presses upon the ovary, giving pain. If the ovary were a little lower than it is, there would be another symptom; *i.e.*, when the fæces were at all hard and there was straining when the bowels were moved, there would be pain radiating down the leg. She does not have much pain at this time, but feels a chill from her head to her feet. In reply to a question, she tells me that there is pain in the marital relation. The pain would be worse if the ovary were in the median line in Douglas's pouch, but it is in the lateral pouch, and is not so much impinged upon.

What shall we do for her? The proper plan is to give some remedy which will lessen the flow of blood to the ovaries. I shall give her ammonium chloride in combination with ammonium bromide, as follows:

R Ammonii chloridi, ℥iv;

Ammonii bromidi, ℥iv;

Infus. gentianæ comp., ℥vi. M.

Sig.—A dessert-spoonful before each meal.

If it prove too irritating for the stomach, it may be given after meals, in water. She will also take ten drops of tincture of digitalis, three times a day. This, besides being a heart-tonic, lessens the amount of blood going to these organs. At the end of a week we shall be able to give the iron preparation before mentioned. She is not now in a condition to take iron. It is best to prepare her for the iron by the use of a purge and the administration of such remedies as the chloride of ammonium. With the iron she will receive strychnia. Sometimes iron cannot be given because it increases the flux of blood. She will also need a properly-fitting pessary. I think that, if the melancholy is not due to incipient insanity, she will be greatly improved.

ORIGINAL COMMUNICATIONS.

REPORT ON THE PROGRESS OF MEDICAL CHEMISTRY.

BY WILLIAM H. GREENE, M.D.

THE CHEMISTRY OF URINE.

PARAXANTHINE.—By operating on large quantities of urine, G. Salomon has succeeded in extracting a new matter which he calls *paraxanthine*. The urine was collected in vessels containing a small quantity of nitric acid to prevent ammoniacal fermentation, and, in quantities of twenty-five to fifty litres, was rendered alkaline with ammonia. 0.5 or 0.6 gramme of silver nitrate per litre was added, and the dirty-white precipitate collected and washed as long as the washings contained chlorides; it was then suspended in water and decomposed by hydrogen sulphide, and the filtered liquid evaporated until an abundant deposit of uric acid was formed. The remainder of the latter acid was precipitated by an excess of ammonia, and the new filtrate obtained, after standing two days, again precipitated by silver nitrate. The compound of silver nitrate and hypoxanthine was thus separated, while xanthine and the new substance remained in the mother-liquor, from which they were precipitated by the addition of ammonia. This last precipitate was decomposed by hydrogen sulphide, and the clear liquid treated with ammonia, evaporated to small bulk, and again filtered. On crystallization, xanthine separates first, and from the strongly concentrated mother-liquor the paraxanthine is deposited in large colorless hexagonal tables. It is slightly soluble in cold water, much more soluble in hot water, and insoluble in alcohol and ether; the solution is neutral. No hydrochloride could be obtained, but the substance combines with the alkaline hydrates, forming microscopic crystals, which are precipitated when potassium or sodium hydrate is added to a concentrated solution of paraxanthine. Successive treatment with nitric acid and caustic soda produces a pale-yellow color. Weidel's test (evaporation with chlorine water and a trace of nitric acid, and contact of the residue with ammonia vapor) develops a rose color. From twelve hundred litres of urine only 1.2 gramme of paraxanthine was obtained, and new experiments must show whether this substance, to which the formula $C_{15}H_{17}N_9O_4$ is

assigned, pre-exists in the urine or is formed during the manipulations.

UROSEÏNE.—This substance is the cause of the rose color assumed by many specimens of urine several minutes after the addition of strong hydrochloric or dilute sulphuric acid. Nencki and Sieber have never found it in normal urine, but in about ten per cent. of pathological specimens; these represented the most varied affections,—diabetes, chlorosis, nephritis, typhoid fever, carcinoma of the œsophagus, etc. The diet appears to have no influence on the appearance of this substance in the urine: in the same case it may disappear for a few days and its elimination be resumed as before. Its detection is not difficult. To fifty or one hundred cubic centimetres of urine, five or ten cubic centimetres of sulphuric acid diluted with three times its weight of water are added, and then a few cubic centimetres of amyl alcohol. The tube is agitated, with precautions that the mixture may not form an emulsion, and the alcohol, dissolving the uroseïne, separates with a bright rose color. The solution causes a spectroscopic absorption-band between D and E, and concentrated solutions allow the passage of only red and orange rays. Ether, chloroform, benzol, and carbon disulphide do not remove uroseïne from the urine. Ammonia and solutions of the alkaline hydrates and carbonates decolorize the solution of this coloring-matter, but the color reappears on the addition of an acid. Powdered zinc agitated with the acid solution bleaches the color in the same manner, but it is restored on exposure to the air. Uroseïne is unstable, resembling in this property the red coloring-matter of the retina: urine which has assumed a rose color by the addition of an acid is spontaneously decolorized after standing a few hours; after evaporation of the alcoholic or aqueous solution only a resinous brown matter remains. However, by the following process a solution is obtained which may be kept for several weeks: a few litres of the urine are rapidly concentrated to half the volume in flat dishes on a water-bath; after cooling to 30° C., hydrochloric acid is added, and the color is fixed on clean wool, sodium acetate being added if necessary. The wool is then carefully washed in water, dried in the air, and digested on a water-bath with absolute alcohol containing a little sulphuric acid.

The alcoholic solution so obtained is the purest and most stable which the authors could prepare.

LACTIC ACID.—Nencki and Sieber have found that even large doses of lactic acid—twenty grammes of sodium lactate per twenty-four hours—are completely oxidized in the human body in glycosuric conditions as well as in health. This observation is entirely contradictory to the statement of a large number of experimenters that normal human urine contains lactic acid. The authors have consequently made a critical examination of all the publications on the subject, and conclude that, except in two cases, one of which was acute phosphorus-poisoning and the other trichinosis, in which the lactic acid was isolated from the urine and its zinc salt analyzed, none of the analyses warrant the conclusion that lactic acid exists in human urine. To a case of diabetes, in which from 400 to 600 grammes of glucose were eliminated in twenty-four hours, and in which it might consequently be supposed that the oxidizing powers of the system were very low and that no foreign matter would be burned, twenty grammes of neutral sodium citrate and sodium lactate were administered per day, and the urine contained neither citric nor lactic acid. On the contrary, injections of benzol were followed by the appearance of notable quantities of phenol in the urine. In a case of leucocythæmia, in which the daily excretion of uric acid was increased to one gramme, not only could no lactic acid be detected in the urine, but the patient was still able to oxidize twenty grammes of sodium lactate per day. These results are important in relation to the pathology of diabetes and other affections in which we would be tempted to conclude that no such oxidations could occur.

ACETYL-ACETIC ACID.—The violet or red color produced by the addition of ferric chloride to urine is attributed by Tollens to the presence of acetyl-acetic acid, and Rudolf von Jaksch has confirmed the opinion. By agitating with ether urine acidulated with sulphuric acid, shaking the decanted ether with water and cupric hydrate, rapid evaporation of the solution in a vacuum, and extraction of the residue with absolute alcohol, Jaksch obtained a copper compound the analysis of which gave the figures required by the compound of acetyl-acetic acid. The

salts of zinc, barium, and ammonium were prepared from urine in the same manner, and the results fully sustained the indications furnished by the copper compound. These salts decompose rapidly in solution, as does also the free acid, which disappears from fresh urine after standing twenty-four hours, and more quickly if the urine be warmed.

DETECTION OF GLUCOSE.—Gautrelet remarks that we may readily distinguish between a reduction of the cupro-potassic solutions by glucose and a similar reduction by uric acid. The reduction by glucose takes place as soon as the liquid begins to boil, and is not increased during cooling. If, however, a reduction begins when the tube is withdrawn from the flame, and continues during cooling, it is to be attributed to uric acid.

DETECTION OF ALBUMEN.—Arthur R. Haslam finds that a very dilute solution of albumen, to which a little common salt is added, is precipitated by ferric chloride, and proposes the use of the latter for the detection of albumen in urine. The test is worthy of no confidence, for the author himself directs that acetic acid should first be added to the urine in order to prevent the precipitation of the ferric chloride by the phosphates. The precipitation of albumen by ferric chloride and by ferric acetate is a long-known fact, but the precipitate is soluble in an excess of the reagent.

ESTIMATION OF UREA.—L. Hugounenq estimates urea by heating five cubic centimetres of urine, previously filtered through animal charcoal, with fifteen to twenty cubic centimetres of water to 190° C. in a sealed tube. The quantity of ammonia formed is then determined by the aid of a normal sulphuric acid containing forty-nine grammes of sulphuric acid per litre. The required number of cubic centimetres multiplied by six gives, in grammes, the quantity of urea in a litre of urine. This method is not applicable to urine containing sugar; that containing albumen must first be boiled. The process is quite as troublesome as that of Bunsen, over which it possesses no advantage.

BILE-PIGMENTS AND ACIDS.

E. Drechsel proposes the substitution of phosphoric acid for sulphuric acid in Pettenkofer's reaction. The solid substance to be tested, together with a grain of

sugar, is dissolved in one to three drops of a mixture of five volumes of syrupy commercial phosphoric acid and one volume of water. The test-tube is warmed by immersion in boiling water.

According to St. Capranica, solutions of bilirubin and biliverdin in alcohol, ether, or chloroform assume, after the successive addition of bromine, water, chloric acid, and iodic acid, a green color which deepens to blue and violet, then changes to orange, and finally disappears. The conversion of bilirubin into biliverdin is effected in neutral solutions by the action of light, and the former compound may so be distinguished from the hematoidin of the corpora lutea, whose solution is decolorized by exposure to light and does not become green. Whether the hematoidin of old apoplexies is identical with that of the corpora lutea is still doubtful. St. Capranica considers it improbable that the bile-pigments are derived from the coloring-matter of the blood, notwithstanding that they are related by many properties, as by their reduction, which in each case yields hydrobilirubin. Solutions of the latter do not become red on addition of bromine-water, but are colored violet-red by the chloric and iodic acid. A sharper test consists in agitating an ethereal solution of hydrobilirubin with aqueous iodic acid, which so acquires a violet-red color.

TIME REQUIRED FOR STOMACHIC DIGESTION.

E. Jessen has made some experiments on the time required for the digestion in the stomach of several articles of diet. The stomachs of the persons submitting to the experiment were emptied by the aid of a pump, and one hundred grammes of raw or cooked meat mixed with three hundred cubic centimetres of water were introduced. The experiment was considered ended when the stomach-pump could remove no particles which exhibited the microscopic appearances of muscular fibre. The results were as follows:

Raw and finely-cut beef,	2	hours.
Partially-boiled "	2½	"
Well-boiled "	3	"
Rare roast "	3	"
Well-roasted "	4	"
Raw mutton,	2	"
Raw veal,	2½	"
Raw pork,	3	"

The digestion of milk was examined in the same manner, a quantity of milk being used of which the percentage of nitrogen was equivalent to that of one hundred grammes of beef.

602	cubic centimetres	raw	cow's milk,	3½	hours.
602	"	boiled	"	4	"
602	"	sour	"	3	"
675	"	skimmed	"	3½	"
656	"	raw goat's milk,		3½	"

A SUGAR-LIKE BODY EXTRACTED FROM THE LUNGS AND SALIVA OF PHTHISICAL SUBJECTS.

A. G. Pouchet has by a somewhat complicated process extracted from the saliva and lung-tissue of consumptives a carbohydrate having the composition $C_{12}H_{20}O_{10}$. It is an amorphous white powder, the aqueous solution of which rapidly becomes brown and mouldy. It does not reduce Fehling's solution, but acquires reducing properties by boiling with acids. It is feebly dextrogyrate. It produces a cloudiness with silver-nitrate solution, and soon afterwards a separation of metallic silver. It is distinguished from glycogen by its reactions and by its perfect solubility in water.

BORIC ACID AS A FOOD-PRESERVATIVE.

J. Forster has made some experiments on the influence of boric acid on digestion. Starting with the assumption that the most perfect digestion is that which furnishes the least quantity of solid excrements, he weighed the dried excrements, estimating also the nitrogen, of an individual who was kept on a constant diet of eggs and milk. During certain periods of two or three days this food was administered pure, and during similar periods with the addition of from 0.5 to three grammes of boric acid. The results indicated that the boric acid increased the quantity of dry excrements and nitrogen. Some experiments seemed to show that the proportion of albuminoid matters contained in the excrements was also augmented by the ingestion of boric acid. The author remarks that, should these results be confirmed by more extended experiments, boric acid must no longer be highly esteemed as a food-preserver, and that particularly must attention be given to the fact that this substance is frequently added to milk intended for the use of infants and invalids.

FIBRIN AND FIBRINOGEN.

Denis distinguishes three modifications of human fibrin: 1st, *concrete modified*

fibrin, obtained by whipping arterial blood or by diluting with water venous blood received in a solution of sodium sulphate; this is insoluble in solutions of common salt, and identical with ordinary fibrin; 2d, *concrete fibrin-globulin*, from venous blood coagulated by rest; this is swollen and gelatinized by ten-per-cent. salt solution; 3d, *concrete pure fibrin*, formed by beating venous blood, perfectly soluble in salt solutions. The difference between these varieties, which has been denied by Eichwald, is in the main sustained by Hammarsten, who considers the first-named insoluble variety as the type. The gelatinization, or the second variety, may be produced from fibrin by the addition of a large proportion of white blood-corpuscles. The third and soluble variety, which Denis obtained from human blood by adopting special precautions, Hammarsten has prepared from the fibrinogen of horses' blood by taking advantage of a characteristic but not entirely typical property of that substance, by the addition of a large quantity of paraglobulin or an insignificant amount of free alkali; carbonic acid retards the change, but does not exert any modifying influence on the resulting fibrin. The later researches of Hammarsten indicate that, besides the necessary salts pointed out by Schmidt, only two bodies are required for the production of fibrin: they are fibrinogen and the fibrin ferment; paraglobulin may increase the production, because it opposes certain of the influences preventing coagulation of the natural fibrinogen solution. Hammarsten's estimations of the fibrin yielded by solutions containing no paraglobulin agree perfectly with those of Schmidt and Frédéricq; the fibrinogen always yielding less fibrin than would be required by its weight,—from 61.63 to 94.1 per cent. Fibrinogen coagulating at 56° C. disappears rapidly from its solutions, which then contain a new globulin, precipitated by magnesium sulphate and more readily by sodium chloride than is paraglobulin; this globulin coagulates at 64° C., and exists also in the serum of blood. By warming a fibrinogen solution to 50°–60°, an insoluble substance coagulates, and the liquid then contains the globulin coagulable at 64°. The insoluble substance contains more nitrogen than does fibrinogen; the soluble substance consequently containing less. Hammarsten does not

consider these products to be formed by decomposition, which would otherwise yield them in constant proportions. Agreeing with Denis, he believes that there is a soluble intermediate fibrin formed during the coagulation, and that this is at least partly, and perhaps by oxidation, converted into globulin.

SUCCESSFUL OPERATION FOR VESICO-VAGINAL FISTULA.

BY HILLARY RYAN, M.D.,

Caldwell, Texas.

OF all the ills that flesh is heir to, I know of none in which there is no danger to life, and but little to the general health, that entails on the poor sufferer so much discomfort and mortification as vesico-vaginal fistula.

The physical discomfort is great, but the mental suffering is greater. The constant dribbling of urine keeping the parts wet and excoriated, with the offensive smell, produces a condition which alone is sufficiently painful to elicit the sympathies of all connected with the unfortunate sufferer. But when we remember that the organs that a modest woman desires to be kept from the thoughts and attentions of those with whom she is surrounded are constantly kept vividly in her own mind, and, as she necessarily supposes, in the minds of those with whom she is associated, her chagrin excites our warmest sympathies. After reading the history of the many efforts to cure this distressing affliction, we feel surprised that more had not been done centuries ago than was done; and we are further surprised that better success did not crown the efforts at first of those eminent surgeons that did attempt the relief of this unhappy condition. Dr. J. Marion Sims says that he operated on three cases about forty times without making a perfect cure. The operation in the hands of Dupuytren, Jobert, and Velpeau was not encouraging.

Yet, with all those failures, the operation can now be performed on healthy subjects with perfect success, by following out the principles so clearly laid down by the well-known writers on the subject. Concerning the *technique* of the operation, we notice that Gosset* recommended

gilt silver-wire sutures. Hayward† advised the very free vivifying of the edges of the fistula. Mettauer‡ recommended lead wire because it could be tightened.

Dr. J. Marion Sims, in an elaborate article published early in 1852,§ advised that the sutures shall not enter the bladder, but pass through the edges of the fistula before entering the mucous membrane of the bladder.

These principles are all collected in an excellent article|| by Dr. Walter F. Atlee, who, with them, gives the additional advice to pass the sutures out some lines from the mucous membrane of the bladder, so as to make a ridge in the bladder when the fistula is brought together, instead of a sulcus.

In Dr. Atlee's operation a broad raw surface is made in the vagina, fully one-third of an inch from the edge of the fistula, and the sutures being passed in this way, at some distance from the mucous membrane of the bladder, the orifice is closed by twisting the wires together, as usual.

Dr. Atlee justly claims for his operation that there is a contact of surfaces instead of edges, and that a crest projects into the bladder instead of the depression into which the urine settles and finds its way into the sutures. The method by which this has been accomplished is readily understood.

Dr. Myers, of Lyons Station, sent to me for operation Caroline Jackson (colored). She was 33 years old, of medium size, stout, and had given birth to six children,—the last one in November, 1881. This had been a tedious labor, and had resulted in vesico-vaginal fistula. On examination, on the 5th of May, I found the fistula about half an inch in front of the mouth of the womb. It was large enough to admit my index and middle fingers. The right proximal edge was somewhat bound down to the os pubis, so that the distal and proximal edges would not meet well in apposition.

Before preparing her, or rather to prepare her, for the operation, I introduced into the urethra sponge tents, so as to dilate the urethra and raise the vagina as much as possible from its attachments. I passed them directly into the bladder. When

§ Ibidem, January, 1852.

|| Ibidem, January, 1882.

* Lancet for November, 1834.

they enlarged, I tore off the end in the bladder through the fistula, and withdrew it, as it made her quite sore. I waited a few days before introducing a larger one. By this means I lengthened the proximal edge so that it would meet the distal pretty well.

Having prepared her in the usual way by purgatives, on the 28th of May, assisted by Drs. Darr, Womach, Matthews, Cearnals, and Armstrong, I proceeded to operate as advised by Dr. Walter F. Atlee in the article referred to, except that I had her nearly on her elbows and knees.

We placed her on a table before a south-west window at two o'clock P.M., her body raised by bedquilts rolled up and placed under her abdomen so as to raise her hips until her knees would rest on the table. While in this position, with her shoulders a little raised from the table, her right hip a little more elevated than her left, the perineum well held back by a Nott's speculum used as a Sims's, and the vulva held apart by two spatulas, the patient being fully under the influence of chloroform, I vivified the vagina and the edges of the fistula with a Bozeman's knife, with the aid of the bistouries and scalpels such as are usually found in a pocket-case, for fully half an inch all around the fistula, going down on the edges to the mucous membrane of the bladder. This stage of the operation was tedious and troublesome.

There was but little hemorrhage, and that was easily controlled by ice placed on the parts.

After the arrest of the hemorrhage we commenced at the right side, where we found the worst adhesions and the most difficulty in making the ligatures meet and pass. We used a short, curved needle, armed with a silk thread tied at the end, in which was looped a silver wire. The needle was passed into the vagina one-third of an inch from the edge of the vivified surface, brought out in the middle of the raw surface, passed into the distal side opposite the place it was brought out of the proximal edge, and carried out one-third inch from the vivified edge on the distal side, just in front of the mouth of the womb. The silk was then drawn through, drawing the silver wire with it, until the wire, which was eighteen inches long, was half through. The ends were now fastened together and another stitch

made in the same way, until we completed the twelve which it took to reach the left side. We then again commenced, but on the right side, and with a fenestrated ball-forceps passing the wire through the fenestræ until the points of the forceps were within half an inch of the vagina, when I twisted the wires until I brought the parts together. I continued in like manner with all until the parts were well drawn together; but, upon close examination, I found that I had not commenced close enough to the edge, and so I put in another stitch at the right side. I then fastened the wires together with a piece of dressed buckskin. Having replaced her on her back, I introduced a silver catheter into the bladder, and with a Davidson's syringe washed out the bladder with warm water, and then the vagina. I then placed cotton-wool, saturated with laudanum, in the vagina over the fistula. Then, the operation being completed, I introduced a gum catheter into the bladder and placed her on a mattress.

28th. Morning. Temperature 101° , and badly nauseated. I thought the nausea was possibly from the chloroform and a dose of morphine given her. I gave her ice *ad libitum*, washed out the bladder and vagina, and replaced the cotton and laudanum. Iced milk-whey for diet.

29th. Evening. Washed out the bladder and vagina with warm water, and replaced the cotton and laudanum.

30th. Temperature 100° . No nausea. I washed out the bladder and vagina, and renewed the cotton and laudanum.

31st. Temperature normal. No pain in any part. Washed out the bladder with warm water; renewed the cotton and laudanum; changed catheter. At every dressing the catheter was cleansed, but we found it necessary to replace with a new one every day or two.

On the 1st, 2d, 3d, 4th, and 5th of June the treatment was the same, except her diet, which was of wheaten bread, tea, and milk. No other diet allowed; but she was allowed tea or milk as she chose.

6th June. When we used the warm injection in the bladder, blood issued from the vagina. We were greatly troubled, fearing that the operation was not a success; but when the woman who nursed her came, she suggested that it was her "sickness" on her. We examined the parts as best we could, and could see noth-

ing to indicate ulceration or that the stitches had given way. We still used the same washings and opiate applications. Her menses lasted until the 10th, then ceased. On the 11th I ordered an enema to move the bowels, and it acted well.

15th June. I was summoned to Lampasas on professional business. Before leaving, I cut off the wires at the vulva, which she thought I "ought to have done at first," and let her walk around as she pleased. I was detained at Lampasas three weeks. On returning I found our patient well.

At this visit I found five of the sutures on the left had grown out. I cut off the distal end of the others and carefully drew them out also. In two weeks more, one could not have told where the fistula had been. I think it wholly unnecessary to leave the sutures in so long, but in this instance I feared sexual intercourse, which the wires prevented.

I think that this case demonstrates the truth of the assertion of Dr. Atlee that, if broad, raw surfaces are fastened together by sutures, not entering the bladder at all, the sutures, of silver or gilt silver, being introduced so as to make a crest in the bladder instead of a depression, and a contact of surfaces in place of edges, the operation will be a success no matter what kind of instruments you use. For in this instance, with the exception of a Nott's speculum used as a Sims's and a Bozeman knife, I had nothing but what was improvised for the occasion. I may have been extravagant with wire,—for I used up about twenty feet,—but the subsequent progress showed that no case could have done better.

AN EXAMINATION OF THE FÆCES OF TWENTY PERSONS RECEIVING INUNCTIONS OF COD-LIVER OIL.

BY N. A. RANDOLPH, M.D.,

Assistant Demonstrator of Physiology, University of Pennsylvania, Instructor in Physiology Towne Scientific School,

AND

A. E. ROUSSEL, M.D.,

Resident Physician at the Philadelphia Hospital, Late Resident Physician Orthopædic Hospital.

IN a study of the fæces of starch-fed infants* one of us observed a specimen in which there was present a very notable

amount of oil-globules. Upon inquiry, it was found that the child in question had been receiving inunctions of cod-liver oil.

The same coincidence was a second time noted, and the following series of experiments was then instituted.

The fæces of fourteen infants, in fairly average health, were examined with negative results as far as oil was concerned, except in one case.

These infants were then thoroughly rubbed with cod-liver oil twice daily for eleven days, care being taken to cleanse the surface of the body after each inunction, and the fæces of each examined for oil at the end of the third and of the eleventh day of inunction. At the end of the third day, traces of fat were observed in the majority of the specimens. On the eleventh day all but three specimens exhibited, on microscopical examination, a decidedly notable quantity of unabsorbed fat,—numerous oil-globules being apparent in every field.

In like manner an examination was made of the dejecta of six adults, after which each was twice daily well rubbed with cod-liver oil in the groins and axillæ for a period of three weeks. The fæces of the adults contained normally much more fat than those of the infants, but in all but one case there was a well-marked increase in the proportion of fatty globules at the end of the treatment.

The circumstances of the examination precluded the application of the ether method for the estimation of fats, and we were forced to rely upon a close microscopical examination. For the micrometric method only relative accuracy is claimed, and we hope soon to be able to go over the same ground, substituting a chemical for the optical method in the determination of fats. By the use, however, of well-mixed specimens, and by carefully averaging the contents of many fields from the same specimen, we have obtained results which we believe accurately represent the changes in the *relative* proportion of fat in the specimens examined, although the unit assumed may not correspond with that obtained by gravimetric methods.

The individuals under observation were upon a diet practically uniform in composition and quantity, both before and during the treatment. At the end of the period of inunction a marked gain in

* Randolph: Transactions of the College of Physicians of Philadelphia, 3d series, vol. vi. p. 443.

weight and general health was noted in the majority of the cases.

The results of our study are indicated in the following table :

cases, and that by the application of this test both the frequency of exhibition and the amount of a remedy rather repugnant to the average patient may be reduced to

No.	Age.	Diet.	Fat in Fæces before Inunction.	After Three Days' Inunction.	After Eleven Days' Inunction.
1.....	2 months	Milk and crackers	Negative	Negative	Negative
2.....	3 "	" "	" "	" "	3 per cent.
3.....	4 "	" "	" "	Traces	3.5 "
4.....	5 "	Corn-starch and milk	" "	" "	5 "
5.....	5 "	Milk and crackers	" "	" "	3 "
6.....	5 "	" "	" "	Negative	Negative
7.....	6 "	" "	Traces	Traces	Traces
8.....	6 "	" "	Negative	Negative	3.5 per cent.

10.....	11 "	" "	" "	Traces	3.5 "
11.....	12 "	" "	" "	" "	3 "
12.....	14 "	" "	" "	" "	3.5 "
13.....	14 "	" "	" "	" "	2.5 "
14.....	15 "	Corn-starch and milk	" "	" "	3.5 "

No.	Age.	Diet.	Fat in Fæces before Inunction.	Fat in Fæces after 21 Days' Inunction.
1	Adult.	Hospital Diet	Traces	Traces
2	"	" "	2 per cent.	5+ per cent.
3	"	" "	2 "	10+ "
4	"	" "	3 "	10 "
5	"	" "	Negative	Traces
6	"	" "	"	"

It will be seen, from the table given above, that in eighty per cent. of the cases a notable increase of the fatty matters passed per anum was observed after the persistent inunction of cod-liver oil. In the remaining twenty per cent. the quantity of fæcal fats was unaltered by the treatment, and in one case remained negative throughout.

We venture to suggest, as a provisional hypothesis, that by the continued inunction the circulating fluids became to some extent surcharged with fats, and that, in consequence, a certain amount of the fatty constituents of the food was refused by the absorbent surfaces of the intestine and passed from the body unaltered. This supposition is strengthened by the observations of Berthe,* who showed that pure cod-liver oil, given internally, could be taken for a longer time without appearing in the fæces, than could an equal amount of butter or any of the other animal and vegetable fats.

We further suggest that, in practice, the increase of fat in the stools constitutes a physiological test for the efficiency of the aliptic treatment in the great majority of

the minimum necessary for efficient treatment.

BIOLOGICAL LABORATORY OF THE
UNIVERSITY OF PENNSYLVANIA,
November 10, 1883.

NOTES OF HOSPITAL PRACTICE.

PENNSYLVANIA HOSPITAL.

CLINIC OF DR. R. J. LEVIS, ONE OF THE ATTENDING SURGEONS TO THE HOSPITAL.

Reported by GEORGE F. SOUWERS, M.D.

REMARKS ON FRACTURES.

GENTLEMEN,—During the course of the college term I endeavor in this hospital to demonstrate as far as possible all the different forms of fracture. Nearly all the common forms of this surgical injury, and many uncommon ones, are thus brought to your notice in the lecture-room of this institution.

CASE OF FRACTURE OF THE FIBULA.

In pursuance of this plan, I bring before you this morning the individual to whose case I now call your attention. Before examining him, I shall premise that he met with his misfortune through being thrown off a street-car, striking upon the ground with his foot turned laterally, the result being, as I shall demonstrate to you, a form of fracture which is nearly always produced by falls or twists with the foot turned in this particular manner. The fracture referred to is that of the fibula, the seat of injury usually being about one and a half or two inches from the lower end of the bone, or the outer malleolus alone may be chipped

* L'Union Médicale, t. x. No. 62, 1856.

off; but we find the most common seat to be, as I have said, about an inch and a half to two inches above the lower extremity, at the point where the bone is thinnest. The fracture of this bone may be very simple in character, or it may be complicated by reason of a dislocation also of the astragalus, constituting the celebrated "Pott's fracture."

It is, when simple and uncomplicated, a fracture that is very likely to deceive one. Not unfrequently has this fracture been mistaken for a simple sprain of the ankle, for while at times there may be great deformity of the leg in the victim of this accident, yet we cannot say that there is always deformity. The most marked evidences of the fracture are the great lateral mobility of the foot, and the outward displacement of the ankle and foot. Knowing now what I have just told you, you must remember to watch cases of this kind narrowly and examine them critically. There are two methods by which you may arrive at a diagnosis. One is to grasp the foot and move it outwardly and then inwardly towards its normal position; this process will, of course, elicit crepitation, and this, together with the pain produced as you force the foot out, and its extreme range of lateral motion, will indicate with what you have to deal.

The method of procedure just spoken of answers very admirably where the patient is not fleshy, and where the fracture is decidedly marked by greater or less deformity, and possessing all or most of these features characteristic of the fracture, and which will distinguish it from simple sprain.

If now, however, you come in contact with a case of this fracture where there is but little displacement, or where the patient is very stout, fat, or muscular, you will not unfrequently find great trouble in arriving at a satisfactory conclusion as to the injury present. There is one method under such circumstances which I have tried and found to answer most admirably, and that is this: feel for the head of the fibula just near its junction with the tibia, in the neighborhood of the annular ligament; at this point make decided pressure so as to produce a tilting motion at the distal end of the bone; if fracture is present, pain will be felt, not at the spot at which pressure was made, but at the point of fracture; if you thus elicit pain you can rest assured of the diagnosis, and can direct your treatment accordingly. I may

say here that this fracture is peculiarly the fracture of the leg consequent upon falls from a height, especially where the man strikes with the foot slightly everted. Fractures from a misstep, as where one falls in walking from the pavement to the gutter with the foot everted, nearly all take place here. Further, where there is lack of co-ordination in walking, as in drunken men, fracture of the leg, if it takes place, seems to select the lower end of the fibula as its favorite seat: indeed, so commonly do we admit drunken men to this hospital suffering under this lesion that I call it the "drunken man's fracture." As to treatment, do not imagine, as many seem to do, that because you apply a certain form of splint or bandage, the reduction of the fracture is thereby accomplished and the cure fairly inaugurated. Let splints for this or any form of fracture be your last thought: you can arrange splints according as circumstances and cases arise: your judgment must dictate to you what kind to employ, and not any set rule or form. Let, then, your first and primary object be the proper reduction and coaptation of the fragments. The medical mind seems to be so associated with splints for fractures that not enough care is bestowed on this item of proper reduction. A pillow for the leg and foot to rest upon, and to make equable pressure in order to retain the parts properly *in situ*, together with a fracture-box, will answer all purposes in ordinary, simple cases, and complicated cases, of course, must be, as I have said, treated on their merits.

FRACTURE OF THE STERNUM.

In this, our next case, we have an extraordinary case of fracture. While in private practice it is rare to see the form of injury we are about to examine, yet in this institution we see it with a fair degree of frequency,—that is, considering its acceded rareness. For instance, in the past two months two cases of the kind have been admitted to the wards, one of them being the case before you. This man, while at work, had a wall fall upon him, the result being a fracture of the sternum, or what generally is classed under that head. As a rule, the so-called fracture of the sternum consists of a dislocation of the manubrium, or upper segment of the bone, and this, I think, is what took place in this case. Of course we may have true frac-

ture and even comminution of the sternum, but this is generally the result of great, direct violence, as from the passage of a heavy weight across the chest, or a crushing force squeezing the chest, as in bumper and other railway injuries. The most common cause of the accident, as we here see it, is from violence that bends the body over very strongly, a force that carries the shoulders and chest into undue flexion. For instance, a not uncommon manner of this accident's occurrence is where a man working at the bottom of a well has a bucket of earth or a large stone precipitated on him from above; in stooping to protect his head the shoulders receive the impact of the blow, and this is expended ultimately on the sternum. The chest at the point of fracture or dislocation, which is generally situated at or about the second intercostal cartilage or space, is driven in so as to leave a large depression, similar to the one in this man's case, which admits of the burial of his fist in the deformed chest-wall. Indirect violence, as by a fall on the shoulder, will also produce this accident, which, as I have said, is more of an epiphyseal separation than a true fracture. The contiguous ribs stand out prominently and boldly at the seat of injury. The best method of reduction is to pile pillows upon each other under the patient's back till a high fulcrum is formed, over which he is bent backwards by the shoulders; extreme retroflexion is made, until the peculiar snap of the fragments returning into place is heard. In those cases where the accident follows violent direct injury, death generally occurs, in consequence of rupture or injury of the heart, lungs, or great vessels, and nothing can be done for the relief of the victim, such cases not being amenable to treatment. Pressure at the seat of accident will generally elicit pain, as in all other forms of fracture. After reduction the patient should be kept in the recumbent posture and carefully watched for chest-symptoms.

FRACTURE OF THE FEMUR, WITH DELAYED UNION.

At the last clinic I showed you a case of delayed union in a case of fracture of the femur, the patient being a man who was somewhat advanced in life, and who had at various times in his career suffered other forms of fracture, in which delayed union was present. The case I now bring to your

notice shows the same condition, in the femur of a boy about 12 years of age. This boy has had also previous to this a fracture of the bones of the opposite leg below the knee; this, however, healed nicely and without complications. Now, ten weeks after receiving this fracture of the femur, we find a condition of pseudo-arthritis, or false joint, though there seems to be a good deal of callus thrown out around the point of fracture. In some this condition of delayed union seems to be traceable to some vice or debility of the system, as a syphilitic or cancerous cachexia. In others we may have various causes; a piece of tendon, muscle, or bone may by its position prevent proper coaptation and union of the fragments; or we may have a condition that obtains in some cases, —namely, instead of the inflammation following such an injury being an inflammation of repair, it seems to be an inflammation of rarefaction; callus is not deposited, but the ends of the bone become rounded off, attenuated, and flail-like in character. In private practice I have found that too tight bandaging, by interfering with the nutrition of the parts, is a most prolific cause of this disastrous termination of fractures. The best remedy in any case is to build up the system, get the patient out of bed and into the open air, allow him to walk about on the injured leg, having first enclosed it in a permanent dressing, and, by means of the attrition thus produced of the ends of the bone, strive to set up a reparative inflammation. The leg naturally hangs down, and in its normal position with this increased stimulus it may be that sufficient extra circulation may take place in the part to accomplish the desired end.

TRANSLATIONS.

TREATMENT OF WENS BY ETHER-INJECTIONS.—A communication to the *Bulletin Générale de Thérapeutique*, by Dr. Lemoyez, Interne at the Hôpital St.-Louis, Paris, discusses the different methods of treatment of sebaceous cysts of the face and scalp, and recommends parenchymatous injections of pure sulphuric ether. A case is reported of a man debilitated and affected with chronic alcohol-poisoning, therefore a bad subject for a surgical operation, who was relieved of a wen of five years' growth

by ten hypodermic injections of ether practised at intervals of a day or two. The result was the conversion of the tumor into a cyst with fluid contents, the evacuation of the same, and speedy destruction of the cyst-wall by inflammatory action. In the case quoted, the treatment resulted in a perfect cure in a month, without keeping the patient in bed or restricting his movements as would have been required by the ordinary operation.

The advantages claimed for this method are its simplicity, painlessness, and efficiency, without exposing the patient to the risk of a surgical operation or in any way interfering with his business. The injections are made into the interior of the cyst, five or ten drops at each sitting, the needle of the hypodermic syringe being moved about so as to break up the contents as much as possible. They are discontinued when inflammation or suppuration begins.

TREATMENT OF CHRONIC URETHRITIS AND CYSTITIS.—Dr. Guyon lays much stress upon the constitutional treatment with cod-liver oil, arsenic, iodide of iron, the sulphides externally and internally, balsams, douches, etc., according to the diathesis. The local treatment by injections, instillations, and catheterization is also of great value. Injections are only useful when judiciously employed; although most frequently used, they often fail on this account. They are either too strong or not strong enough; they either do injury or they are not efficient. Instillations made with an olive-pointed catheter in which an opening exists at the side of the olive are more valuable. A syringe is adjusted to the other extremity of the catheter, and the instrument is gradually introduced into the urethra until it meets a slight sense of resistance, when five or six drops of the solution are thrown in; after waiting a few minutes, the instrument is introduced farther, and, when it reaches the posterior extremity of the urethra, twenty to twenty-five drops are injected. The medicament usually employed by M. Guyon is the nitrate of silver ($\frac{1}{20}$ to $\frac{1}{50}$); he also uses the sulphate of copper ($\frac{1}{10}$ to $\frac{1}{30}$). Catheterism is not to be practised early, for fear of complications, orchitis, cystitis, etc., but in obstinate cases it may be cautiously used every second day; the metallic bougies are the best for the purpose. Medicated bougies seem to be without utility. Should

blennorrhagic cystitis with hemorrhages occur, it is best treated by instillations of nitrate of silver, which rapidly stop the bleeding. This treatment is also effective in chronic cystitis, which is particularly liable to be persistent and have relapses.—*Bulletin Général de Thérapeutique*, November, 1883.

SPONTANEOUS PYÆMIA.—A young man, 32 years of age, was suddenly taken, without appreciable cause, with muscular pains, and swelling of the sheaths of the tendons of the wrist and of the foot, which appeared rheumatic. Upon examination there was found very marked tenderness and swelling along the course of the tendons in the leg, in the forearm, and in the calf of the leg, present in all of the four extremities, but more marked, however, upon the arm and leg of one side. M. Guyot, who had the case under observation, pronounced it one of pyæmia, but was unable to detect any cause for it. There had not been any traumatism, no trace of any cachexia, no evidence of over-fatigue, no diabetes, no albuminuria, no marked alcoholism. The diagnosis of idiopathic pyæmia was then made. The patient died twenty-four hours later. [The record does not state that the possibility of the case being one of trichinosis had been considered, although some of the symptoms might suggest this explanation.—Tr.]—*Revue de Thérapeutique Méd.-Chir.*, No. 23.

CHARCOAL-AND-CAMPHOR DRESSING FOR WOUNDS.—Barbocci (in *Raccogliatore Medico*) recommends a mixture of equal parts of camphor and animal charcoal as a substitute for Lister dressings. The camphor acts physiologically in destroying microbes, the charcoal physically by absorbing and disinfecting the discharges. This is especially useful in old, excavated ulcers; the application removes fetidity and also relieves pain.—*Revue de Thérapeutique Méd.-Chir.*, December 1.

EDITORIAL.

THE COMPLIMENTS OF THE SEASON.

AS this is the season of the year for compliments, greetings, and mutual wishes for success, we but follow a graceful custom in cordially tendering those of the *Philadelphia Medical Times* to its readers. In doing so we may be pardoned a few remarks upon the standard to be adopted in estimating the measure of professional success, and, perhaps, a suggestion as to its essential elements and conditions. In what follows we will express sentiments which are those of the better portion of the profession, and which we feel certain will meet the approval of our readers.

Action, said to be the secret of oratory, is certainly one of the necessities for success; what is called genius is often merely a talent for steady, persistent labor. But when men are actively striving for progress in the same direction, there is danger that some, in their eagerness for personal advancement, may disregard the rights of others. In a profession, which is distinguished from a business by an elevation of the claims of the mass above those of the individual in certain directions, this danger of encroachment can be avoided only by mutual agreement as to the principles which shall regulate conduct, and the recognition of this truth has led to the establishment of what have been called codes of ethics. Since the introduction of the Code of Ethics of the American Medical Association, it has been observed that the tone of professional intercourse in this country has manifestly improved,* and for this reason it is warmly

* See the address of Dr. John L. Atlee before the American Medical Association this year.

defended, and rightly so, by the great mass of the profession. The Code is now taken as the measure of a physician's duty to his colleagues, and his failure to obey it, in letter or in spirit, in his daily life, is regarded as failure in his highest obligations to his profession. For failure in this duty we feel that no other kind of success can atone, be it political, social, or financial. Too often a superficial estimate of success is made, based upon the apparent material prosperity of an individual; but a little reflection shows that the real standard of success is character, whether in private or in professional life. How often it is that a man's true nature is better known to his associates than he is himself aware! When a man actuated solely by selfish motives enters upon the practice of medicine, and, in pursuit of personal aggrandizement, profanes its solemn and responsible duties, he cannot long conceal this fact from those around him. The success of the charlatan certainly may be his, but never the love and esteem of his professional brethren; and the more self-asserting and the more conspicuous he is, the more obvious and melancholy is his failure. A true estimate of professional success is based upon services to humanity and to the profession. In the real physician, if his life-work be crowned by wealth and honors, they but lend a setting to the jewel; if these linger, success has not been missed. Of the late Dr. J. D. Trask, of Astoria, New York, who died a short time since, and whose death was called a public affliction, an entire community attending his funeral, it was said that "as an author, practitioner, citizen, and Christian he did his work effectively, quietly, conscientiously, and for the work's sake." The *Medical Record*, in whose columns this touching tribute appeared, adds, "It would be well if such could be said of all of us." This is the life and this the success that we cordially wish for all our readers. Its rewards may not be so alluring, but they

are more permanent and satisfying than those of the less honorable course indicated above, which is sometimes considered a successful life, though judged according to a mercenary and not a high professional standard. We owe it to the profession and ourselves to use our best efforts to elevate it, and, in order to do so, we should urge men of lower ambition to—

"Shun braggart glory, crave no sounding name;
Good deeds in heaven's scales weigh more than fame.
All pomp and vain display avoid, although
The foolish world is led by empty show.
Be always what you seem, seem what you be;
With learning couple large integrity.
Through merit seek to rise, and not by dint
Of blazoning your names in public print,
Or pseudo-scientific pamphlets, which
Not science, but their writers seek to enrich
Through wondrous tales of cures adroitly told,
To snare the credulous and filch their gold.
Praise not yourselves, nor others' praises buy;
As men, not showmen, with each other vie.
Upon the public never seek to palm,
With face unblushing and without a quail,
The coin of base, presumptuous pretence
For sterling gold of honest excellence."*

PULSATING EMPYEMA.

DR. COMBY, of Paris, has made pulsating pyothorax the subject of two interesting communications to the *Archives Générales de Médecine* for November and December, 1883, from which we glean the following points in regard to the symptomatology, causation, and treatment of this rare affection, which was first observed by Baillou in 1570.

In all of the twenty-seven cases analyzed by Dr. Comby, the effusion was seated in the left chest, and the symptoms were almost identical. After a certain period, a soft, pulsating, fluctuating, reducible, hemispherical swelling is observed, ordinarily on the lateral lower half of the thorax, although it may be seated in front, or on a level with the præcordial region, or behind and below, near the vertebral column. It may, moreover, occupy the loin, in which event it may be regarded as a perinephritic abscess with transmitted

aortic pulsation, as happened in a case recently in the wards of the Jefferson Medical College Hospital of this city. The pulsations are not expansile, nor are they, as a rule, forcible, nor are a thrill and bruit present, as happens in aneurism. The heart is invariably displaced to the right. The beats are not augmented in force, the rhythm is regular, there is no souffle, nor any other sign indicative of cardiac lesion. During all this time (and the affection pursues a very chronic course) the general health may remain good, or the patient may die before the pus is evacuated. Generally, however, the pus discharges itself spontaneously, the pulsations cease, and signs of pneumothorax set in, the heart rarely resuming its normal position.

In post-mortem examinations, the left lung is found with difficulty, being compressed against and adherent to the pericardium. Its tissues are hard, fibrous, elastic, impermeable to the air,—in a word, sclerosed. Hence the pulsation is due to the beats of the heart being forcibly transmitted by the sclerosed lung to the purulent collection.

The treatment of pulsating empyema is rarely successful, on account of the structural alteration of the left lung, the displaced heart, and the debilitated or tuberculous condition of the subjects. Thoracentesis is, of course, indicated; but the remedy is, as the rule, merely palliative.

In concluding his memoir, the author insists upon the facts that a left pulsating pleurisy is a purulent pleurisy, and that the function of the corresponding lung is entirely abolished, which is a sign of the incurability of the affection.

THE ADDRESS OF PROFESSOR PARVIN, which appeared in our Educational Number, was printed from copy which we received directly from the hands of the author, and we believe it to be the only correct version of his lecture which was published up to that time.

*Valedictory poem, by the late Prof. J. Aitkin Meigs, M.D.

SOMETHING FOR OUR MEDICAL SOCIETIES TO TAKE NOTE OF.

THE Board of Trade of Philadelphia Druggists has passed a resolution, to which the support of a number of our principal druggists is pledged, that after January 1, 1884, the said druggists will positively refuse to keep or deal in those proprietary medicines which are sold indiscriminately to individuals engaged in other kinds of business than dealing in drugs. Certainly, any step of this kind should be formally noticed by our medical societies, which should use every means in their power to discourage the sale of nostrums. The present time may be favorable for the establishment of pharmacies where physicians' prescriptions are compounded and no patent medicines sold.

SHALL THE INDEX MEDICUS BE DISCONTINUED?

IN a circular issued by the publisher, Mr. F. Leyboldt, it is stated that "Five years' publication of the *Index Medicus* has proved conclusively—

"1. That the mere cost of production (per annum) is not less than \$5000. .

"2. That the maximum return from subscriptions, at six dollars per annum, has not exceeded \$3600.

"3. That the increase of subscriptions during the past two years has been merely nominal.

"4. That the limited circulation permits no material return from advertisements."

The publisher also states that he agrees with the editors that, in justice to themselves, as well as to those whose generosity has already been severely taxed, the *Index Medicus* must no longer be dependent on voluntary communications. The undertaking must either be abandoned or at once placed on the business-footing of an equally-shared support. There are about six hundred subscribers, to whom the

question is pointedly addressed whether they will increase the amount of their annual subscription to ten or twelve dollars per annum, if necessary. A prompt answer to this query is needed in order to make the necessary arrangements for the ensuing year, if the work is to be continued. This work has reflected honor upon American medical journalism. It is more than a credit to our medical literature: it has become almost a necessity to all who have occasion to consult it. We feel certain that the profession will not willingly allow it to be abandoned, without some effort to establish it upon a more secure and satisfactory foundation.

LEADING ARTICLES.

PTOMAÏNES.

IN 1872 the late Professor Selmi presented to the Academy of Bologna a paper embodying some curious and interesting results which he had obtained by treating both fresh and partially-decomposed viscera according to the Otto-Stas method for the separation of alkaloids. Although the tissues under experiment could have contained no vegetable alkaloids, he at times obtained extracts which responded to the general tests for these substances, and which corresponded to no compounds which had hitherto been separated from animal tissues. Attributing these reactions to basic compounds of animal origin, he gave to such alkaloid-like bodies the general name *ptomaïnes*.

Several attempts had already been made to isolate the toxic principle of decomposed tissues, but the results were of a character to attract little attention.

Selmi continued his experiments during six years, and in 1878 published a remarkable paper, "*Sulle ptomaïne od alcaloidi cadaverici e loro importanza in tossicologia*," in which he described ptomaïne reactions simulating those of conine, morphine, atropine, and delphinine. Two medico-legal cases had occurred in Italy, in which the first examination had indicated the presence of morphine and delphinine in the cadaver, but in which a second analysis, under the direction of Selmi, had

shown no trace of either of those substances, but the existence of abundant ptomaines.

The importance of arriving at more precise knowledge concerning compounds, the suspected presence of which might invalidate chemical testimony in capital cases, led to the appointment by the Italian government, in 1880, of a commission, composed of the late Professor Selmi and Professors Cannizzaro, Guareschi, Moriggia, Mosso, Paterno, Spica, and Toscani. The expenses of the investigation are, at least in part, defrayed by the government, but the work has been conducted individually. A few papers have already appeared.

In the mean time, several other chemists have engaged in the same line of research, and practically the results have been sufficiently concordant to indicate the existence of a series of ptomaines, of which a limited number have finally been isolated in sufficient quantity to permit of analysis.

Selmi described the first separated of these bodies and the physical characters of its hydrochloride to the Academy Lincei in 1880. The alkaloid resembled conine, and its effects on animals to which it was administered were similar to those of curare. Th. Husemann's experiments afterwards fully confirmed these results.

In 1881 Armand Gautier demonstrated the basic nature of the bodies in question by their power to neutralize strong acids, and by the crystallization of their chloroplatinates, etc. In 1882 the same chemist called attention to the early history of the subject. The first step seems to have been made in 1856, by Panum, a Dane, who obtained from putrefied dog's flesh a poisonous extract, which he called *sepsine*. Eighteen years later Panum maintained the non-alkaloidal character of this poison. Bergmann and Schmiedeberg investigated sepsine in 1868; and in 1869 Zuelzer and Sonnenschein extracted from cadavers alkaloidal substances which they believed to be different from those which had before been obtained. These bodies produced dilatation of the pupil.

Gautier's first experiments seem to have preceded those of Selmi: they are mentioned in his "*Chimie appliquée à la Physiologie*." Indeed, Selmi states that Gautier seemed to have underestimated the importance of his first results, from which he concluded that "these same alkaloids are often produced abundantly in living

animals, and are constant and necessary products of normal tissue-life."

In collaboration with A. Etard, Gautier undertook extensive experiments in 1881. The first researches concerned the different phases of putrefaction. The results indicated that the true putrefactive fermentation begins with the disengagement of nitrogen; the large bacilli and bacteria are then replaced by exceedingly small, tremulous bacilli, having highly refracting heads, some straight, some serpentine. These attack the albuminoid molecules, and there is an evolution of hydrogen sulphide and hydrogen phosphide, while leucines, leucines, skatol, indol, carbylamines, and ptomaines are formed.

By the following process Gautier and Etard succeeded in isolating two bases from putrefied fish (mackerel). The liquid products of the fermentation were separated from oily matter, etc., acidulated with sulphuric acid, and evaporated in a vacuum; the phenol, indol, etc., were thus driven out. The residue was neutralized with baryta-water, filtered, and the filtrate agitated with chloroform. After the evaporation of the chloroform, the residue was extracted with solution of tartaric acid, and the addition of potassium hydrate liberated the bases, which were fractionally extracted with ether, and dried in a vacuum. From the first ethereal extracts a base was obtained having the composition $C_8H_{13}N$. The last extracts yielded another alkaloid, to which analysis seemed to assign the formula $C_8H_{13}N$.

M. Nencki claims to have separated these bases from the products of the decomposition of gelatin in presence of pancreas. From a single analysis of the chloroplatinate, in which he estimated the carbon, hydrogen, and platinum, he gave the composition $C_8H_{11}N$.

L. Brieger, of Berlin, has recently obtained ptomaine reactions from peptones prepared by the action of gastric juice on egg-albumen, and in one case from a commercial peptone. The base could not be isolated, but the extracts manifested decidedly poisonous properties. The following process enabled him to obtain a pure ptomaine. Finely-chopped horse-flesh was mixed with water and kept at a fermentation temperature for five or six days, after which the broth was filtered and the liquid precipitated with lead acetate. The filtrate from the lead precipitate was freed

from lead by means of hydrogen sulphide, and the filtered liquid evaporated to a syrupy consistence and extracted with amyl alcohol. The extract was repeatedly exhausted with water, and the solution evaporated. The watery residue, strongly acidulated with sulphuric acid, was shaken with ether to remove the oxygen acids, and then evaporated to a fourth of its volume to drive out the volatile acids. After precipitation of the sulphuric acid with baryta-water, the solution was treated with mercuric chloride, and the washed precipitate suspended in water and decomposed by hydrogen sulphide. The inorganic salts which first separated on the evaporation of the clear filtrate were filtered out and washed with absolute alcohol. Then from the united liquids an organic substance crystallized in long needles, which were readily soluble in water and alcohol, but insoluble in absolute alcohol, ether, and chloroform. These crystals are the hydrochloride of a base, $C_5H_{11}N$, which decomposes when attempts are made to isolate it from the salt. Half-gramme doses of the pure salt administered to rabbits produced only feeble symptoms of poisoning, but the unpurified extract manifested toxic properties similar to those of the peptone extracts already mentioned. Indeed, the liquid from which this salt crystallized contained another and much more poisonous base, which appears to have the composition $C_5H_{11}N$, being isomeric with piperidine. Administered to rabbits, guinea-pigs, and cats, this compound produced characteristic symptoms, one of the more notable being an abundant secretion of thick, alkaline saliva and nasal mucus. In one case the paws of a cat, dry before the administration of the poison, became bathed in an abundant alkaline perspiration. Internal administration produced the same symptoms as hypodermic injection, but required a much larger dose. In either manner large doses were followed by death after short tonic and clonic spasms.

E. and H. Salkowsky have extracted from putrid flesh and fibrin a basic compound to which their analyses assign the composition $C_5H_{11}NO_2$. This body possesses no poisonous properties, and does not appear to be a ptomaine according to the sense in which that name is received. Its reactions are not described. Its composition is that of an amide of valeric acid.

The most valuable work which has been

conducted is described in a recent memoir by Guareschi and Mosso. The researches appear to have been conducted in a most thorough manner, and the results are of especial importance in that they have led the authors to condemn Dragendorff's method for the separation of alkaloids in medico-legal cases.

They first examined the solvents ordinarily employed,—ether, alcohol, amyl alcohol, chloroform, and benzol.

When commercial alcohol is evaporated to dryness with a small quantity of hydrochloric or tartaric acid, there is always a residue, which, when exhausted with ether according to the usual method for the extraction of alkaloids, yields an extract that responds to the alkaloid reactions. For use in medico-legal cases, or researches for ptomaines, alcohol must be purified by one or sometimes two distillations over tartaric acid.

Ether is sufficiently pure when twice washed with acidulated water and then distilled over lime.

Amyl alcohol (the purest of commerce) contains five-tenths per cent. of pyridine, and its use must be avoided (Uslar and Erdmann's process).

Chloroform may be purified by washing with water, then with solution of potassium carbonate, and final distillation over calcium chloride.

The purest crystallizable benzol of commerce yields, by distillation with potassium hydrate, an aqueous residue containing pyridine.

From these preliminary experiments the authors conclude that all the results heretofore obtained by different observers who used alkaline extracts prepared by means of amyl alcohol and benzol, are absolutely without value, whether the experiments have been made on putrid or on fresh materials.

Thirty-six kilogrammes of human brains were then allowed to putrefy during two months, and the homogeneous broth was treated according to the Otto-Stas method. Only an insignificant quantity of ptomaines was obtained, so small that no analysis could be made. The extract, in doses of 0.0125 to 0.3 gramme, was administered hypodermically to frogs. The effects were analogous to those of curare, but the action was much less energetic, more of the poison being required to produce an effect comparable to that of a given dose of curare:

even when the intoxication was very great it passed off much more rapidly than that due to curare. The larger doses were, however, fatal. Experiments made on a guinea-pig showed that, so far as its physiological action is concerned, "the extract of putrefied human brains cannot be confounded with any of the poisons usually employed in criminal poisonings, for incomparably smaller doses of curare, conine, nicotine, etc., would have produced much more serious symptoms, or would even have killed the animal."

Experiments were made with fibrin, in hopes that the definite and unique character of that body might yield less complex compounds than mixtures of blood, flesh, etc.

The product of the decomposition of eighty kilogrammes of ox-blood fibrin, left to itself during five months, was treated according to the process adopted by Gautier and Etard in the experiments already mentioned. The strongly alkaline extract obtained on the evaporation of the ethereal solutions was neutralized with hydrochloric acid, and the dry residue of a new evaporation formed crystalline double salts with platinic and auric chlorides, and responded to the general tests for alkaloids. An analysis of the platinum compound indicated the composition $C_{10}H_{15}N$ or $C_{10}H_{13}N$. Eleven chloroform extractions were made in these experiments, and each extract was treated separately and the base analyzed. The results were sufficiently concordant with those required by the preceding formulas. If the latter of the two formulas given be correct, this base may be homologous with those obtained by Gautier and Etard. Experiments on frogs and birds showed that the action of these bases corresponded to that of the extract from putrefied brains. The effects of the hydrochloride are more marked than those of the free base.

From fresh brains, treated by the Otto-Stas process within twenty-four hours after death, Guareschi and Mosso obtained small quantities of residues which responded to the general tests for alkaloids.

Perfectly fresh beef was extracted by Dragendorff's method, using sulphuric acid and water, evaporating the liquid to syrupy consistence, and exhausting this syrup with alcohol. Towards the end of the distillation of the alcohol a volatile substance which appeared was condensed in

hydrochloric acid. The residue gave full indications of the presence of alkaloids; and the hydrochloric acid solution, neutralized with ammonia and exhausted with ether, yielded a small quantity of extract having an odor like conine, and responding to alkaloid tests.

In order to determine whether the sulphuric acid used in this operation had caused the formation of these bodies, the experiment was repeated on the same quantity of meat (fifty kilogrammes), tartaric acid being substituted for the sulphuric. The quantity of products obtained was much smaller,—only about one-tenth that yielded by the first experiment,—but a microscopic examination of the platinum precipitate gave evidence of a body very similar to the chloroplatinate of the base extracted from putrid fibrin. "The results obtained by the aid of Dragendorff's process are then very different accordingly as sulphuric or tartaric acid is employed. In the first case an abundant acid-ether extract contained lactic and succinic acids, and there was a relatively large alkaline ethereal extract. Both extracts were much smaller in the second case, and succinic acid could not be detected. These comparative experiments show that in the extraction of fresh animal tissues by Dragendorff's method the products obtained are due, at least in part, to the decomposing action of the sulphuric acid." These experiments show that this method is to be avoided. The Otto-Stas method, on the contrary, yields good results, especially if only that quantity of tartaric acid be employed which will give an acid reaction to the mixture, and the evaporation be conducted at a low temperature, or, better, in a vacuum. Fresh materials treated in this manner yield almost no ptomaines, and successive purifications eliminate them entirely.

Experiments made on fresh meat, without the addition of acid,—and the natural acidity of the flesh justifies this mode of extraction,—showed that the exceedingly small quantities of alkaloidal bases obtained were probably formed during the evaporation of the liquid, owing to alterations in the albuminoid matters. The matter which crystallizes from the ether in this case gives no alkaloid reactions. It was found to be methyl-hydantoin.

These results of Guareschi and Mosso are confirmed by some experiments by F.

Coppola, who extracted from the fresh blood of a healthy dog relatively large quantities of poisonous ptomaines by Dragendorff's method, but, in operations in which no reagents were employed other than the chloroform used for extraction, obtained no evidence of the presence of ptomaines.

The investigations of which we have summarily considered the results have been faithfully conducted by chemists and physiologists concerning whose work there can be no question as to accuracy. The experiments are in one respect unsatisfactory, in that they have not solved the problem of the exact conditions under which ptomaines may be formed. In this they resemble the greater number of chemico-physiological researches. However, the later results are of unquestionable importance in their bearing on the methods employed in medico-legal investigations, and indicate that, when proper precautions are adopted, cadaveric alkaloids need not be confounded with the vegetable alkaloids used as poisons.

The exceedingly small quantities of the bases which have been separated have in so few cases permitted a study of the physical and chemical properties of these compounds, that they are practically recognizable only by the general alkaloidal tests and their physiological effects. For equal doses these effects are so much less energetic than those of other and similar poisons, that careful comparative experiments may remove all fallacy which the existence of ptomaines might appear to indicate as objections to physiological tests in the search for an unknown poison. A neglect of such comparison would at present probably throw doubt even on such results as those obtained by Tardieu and Roussin in the La Pommerais case.

Nothing that has been developed in the study of ptomaines indicates that these bodies are the cause of septic poisoning as we ordinarily understand that term. The alarming blood-poisoning which may follow an insignificant scratch on the finger could be accounted for by the introduction of an infinitesimal quantity of a purely chemical compound into the system, only should that compound possess the energy of the rattlesnake's venom, or should it act as a non-organized ferment capable of profoundly modifying an indefinite quan-

tity of matter. No such ptomaine has been isolated. However, few of the experiments thus far made have thrown light on the effect of time on the stages of putrefaction, and it is possible that the bases present at a given epoch may have existed only during a short period, and may be entirely transformed at a later stage of the almost hopelessly complex reaction. The time, patience, and expense necessary for such researches have limited their number, and the valuable results contributed by Italian experimenters would probably be yet unattained without government co-operation and liberality.

It seems certain that ptomaines do not pre-exist in normal tissues, and it is highly probable that the ptomainic reactions obtained by Gautier from urine, and by Paterno and Spica from fresh egg-albumen and blood, were due to bodies produced during the processes of extraction. The statement of Mourson and Schlagdenhauffen, that ptomaines exist in the amniotic fluid, is open to the same criticism, especially as mere traces of their presence could be detected.

It would not, however, appear strange that under certain conditions the urine, and even the blood, should contain toxic bases. Brieger opens a weighty question in stating that "in a large number of infectious and intestinal diseases death takes place rapidly, and under such circumstances that there can be no other explanation than that of the sudden formation of toxic substances by fermentation in the body." All the recent publications on the genesis of ptomaines are in accord that such genesis does not take place during health. Experiments on conditions of the urine and blood in certain diseases may throw a new light on the immediate cause of death, which may not be due to bacilli, but to the fermentation-products produced by the bacilli. If by changes in the albuminoid matters the blood become charged with poisonous bases, why should not the antidote for such poisons be sought in the laboratory and then applied in practice? This field of physiological research is certainly an open one, and may possibly be as fertile as has been that of pathological microscopy.

WILLIAM H. GREENE.

NOTES FROM SPECIAL CORRESPONDENTS.

CHICAGO LETTER.

NOTWITHSTANDING the excellent laws we now have for governing the practice of medicine, for some reason or other, a score or so of advertising "specialists" have been for a long time more brazen than ever before, and the Sunday editions of the daily papers have contained columns of nastiness in the form of their advertisements.

A few days ago, somebody set the machinery of the law in motion, and quite a number of the "specialists" have been arrested and brought before the court to give bail for reappearance. Spasmodic attempts to enforce the law had been made at different times, but all had ended without accomplishing much.

Let us hope that the present effort may be more successful in permanent good.

Like New York, we have a liberal allowance

of stench-factories, and the Health Commissioner has from time to time tried to suppress their offensiveness, never with complete success, however. The stench-factories now resort to the method of holding in their store of offensive and nauseating gases during the day, and pouring them out during the night or early hours of the morning, when the population is asleep; but those who have open windows, or ventilators connecting with the open air, are painfully reminded how difficult it is to secure a refuge from this great public nuisance.

The building at present occupied as a Hospital for Women and Children proves inadequate for the purpose, and it is proposed to erect a new building calculated to accommodate from eighty to one hundred and fifty patients.

Plans are now being prepared, and the work of construction will at once be pushed forward.

The new Rush College Hospital is making rapid progress, and will be ready for occupation early next spring. The Cook County Hospital has two new pavilions ready for service, giving an increased capacity of about one hundred and fifty patients. The health of the city, in spite of the quacks and the bad odors, remains exceptionally good.

CHICAGO, December 5, 1883.

CORRESPONDENCE.

LONDON LETTER.

WE have recently had a very unpleasant episode in the medical profession,—the more unpleasant in that it shows that the medical profession is not as true to itself as it might be and ought to be. The utility of the nitrites in medicine is now fully established, and a very important armamentarium they have proved. Dr. B. W. Richardson established the effect of amyl nitrite upon the vasomotor system of nerves,—relaxing the walls of the smaller arterioles, and, therewith, lowering the blood-pressure within the arteries. Then Dr. Lauder Brunton, finding the blood-pressure raised in angina pectoris, used the amyl nitrite with marked good effect in a severe case of angina. Since then the use of nitrites has spread rapidly. Then nitroglycerin came up, and in its use Dr. Murrell holds an honored and conspicuous as well as well-won reputation. More recently still, Dr. Law, of St. Leonard's-on-Sea, has used the nitrite of sodium in the treatment of epilepsy, where there is often a rise in the blood-pressure as the fit comes on. Whatever the hypothesis upon which the drug is given is scarcely to the present purpose: the clinical aspect is the one here interesting us. Dr. Law reported a case of epilepsy in which he had given twenty grains of sodium nitrite without any ill ef-

fects. From observations afterwards made by Dr. Ralfe, it seemed that the preparation used by Dr. Law was very impure, being largely adulterated with the *nitrate*: hence the harmlessness of the twenty-grain dose. Unfortunately, the dose of sodium nitrite given in the last edition of Prof. Ringer's famous work on "Therapeutics" is a scruple; and, in consequence thereof, the widest publicity on this matter is desirable, as this is a very dangerous, if not actually lethal, dose of the pure drug. The subject of the impurity of the ordinary sodium nitrite was brought before the profession in October last year, and Dr. Murrell thought it good and desirable to test the action of the nitrite, in order to clear up the subject. According to his explanation, he thought it well to see if sodium nitrite was superior to nitro-glycerin in some maladies, in the interests of his patients,—a perfectly valid and sufficient reason to unprejudiced minds. To one patient ten grains were given without obvious effects, and the dose was raised to fifteen grains. To a second patient ten grains were given with very decided toxic symptoms, of which giddiness, sickness, and a feeling of fulness in the head were prominent. He had also other symptoms. With the experience of the first case before him, Dr. Murrell urged the patient to try it again; but he declined, on the plea that he "had a wife and family." This was put forward rather in joke than in serious earnest, as the man disliked the sensations. Other patients came back complaining of allied disagreeable sensations, and then Dr. Murrell recognized the fact that sodium nitrite possessed toxic properties. He then reduced the dose to five grains, and subsequently again to three grains. He then communicated his observations to Prof. Ringer, with whom he has prosecuted much therapeutic research. Ringer experimented on some cats to test the action of the drug, with such results that a conjoint paper on "Nitrite of Sodium as a Toxic Agent" appeared recently in *The Lancet*. Dr. Murrell has explained, since the thunder-storm arose, "There has been nothing in the shape of experimentation, and I have prescribed nitrite of sodium only in those cases in which, from my previous experience with nitro-glycerin, I was convinced that it would prove useful." The value of a statement depends upon a man's character; and Dr. Murrell bears the reputation of a truthful man. Consequently, this statement may be accepted without reserve. In giving an account of the observations, Dr. Murrell did not foresee that the matter would come prominently before the public, and so laid himself open to attack, which attack was soon made by a suburban clergyman who had seen *The Lancet*. The object of the paper was to point out that two—and not twenty—grains constituted a sufficient dose of Morson's sodium nitrite. To the medical mind the value of such a

paper, under the circumstances, is apparent enough.

The world-wide sale of Prof. Ringer's book called for a prompt and convincing statement of the actual facts. "A plain and straightforward statement of facts" was made. The committee of investigation of the matter stated their opinion on the subject thus: "The sub-committee, after careful consideration of these facts, see no reason why the House Committee should withdraw from Dr. Murrell their confidence in his ability and humanity, and they trust that the unfortunate manner in which the paper was put together will be forgotten, while the value of his experiments will remain. In this connection, the sub-committee would call attention to the fact that, in consequence of this experience, the 'official' dose of nitrite of sodium, hitherto appearing in the standard text-books of therapeutics as twenty grains, has since been reduced to two grains, and a permanent source of danger has thus been averted." A very sensible conclusion, it seems. The clergyman, however, saw only the sensational side of the subject, and wrote a long and forcible letter to *The Standard*, which must have carried joy and delight to the hearts of the anti-vivisectionists, always a lively and obstreperous set. It was said, if experimentation upon animals was stopped, then experimentation upon human beings would follow; and, lo! here was the full and complete verification of the prophecy. Poor hospital patients!—experimented upon when they sought relief from their maladies! Could any more convincing proof of the immoral tendencies of the 'scientific' physician be required or furnished? Howls of execration, attended with delight, went up from the anti-vivisectionists; wails arose from the better-disposed section of society at such lapses in the medical character. Of course, a storm in a teapot blew with an unusual energy. The authorities of University College protested that these experiments had not been conducted at their institution, to which Prof. Ringer is physician. The authorities of Westminster Hospital put in their certificate that it was not in their institution Dr. Murrell had performed his experiments. Where they were carried on I do not know. Then stepped forward one of Dr. Murrell's colleagues (I will refrain from mentioning his name, for which I am sure the day will not be far distant when he will thank me), though it is impossible to avoid commenting on what he has said and done. He wrote a letter to *The Standard*, signed "A Hospital Physician," but subsequently in a signed letter to the *British Medical Journal* he repeats what he said in his previous letter. As a colleague, it was scarcely his duty to step forward to lash Dr. Murrell; as a physician who is not specially known in connection with experimental research, he was not particularly involved. However, he did come

forward to assail his professional brother; and, after assaulting him under a *nom de plume*, he throws off all disguise and goes for him again in his own name. He thinks it necessary to the good name of the profession to set his face against such proceedings; and, while his courage may excite the admiration of some, his temerity has roused the indignation of others. The editor has come down upon him hotly, as the following extract will show: "With the chivalry which rushes into print in a lay journal, under a pseudonyme, to hand over a brother practitioner to the tender mercies of 'a hostile party' in the public press, and helps, 'in the name of science and humanity,' to brand his reputation with levity and flippancy in the discharge of his difficult and sacred duties, we have no sympathy."

The Medical Press and Circular eases its mind in emphatic language upon the subject "of open-handed attacks made by one physician against another. We have, unfortunately, had occasional, but still rare, examples; but never, even in the worst cases of professional bickering, do we remember an instance in which cowardly resort to anonymous publication has been adopted by any one of position in the world of medicine. Bad as the original offence was in the sight of every honorable person, it is greatly intensified by the ill-judged letter which he has set forth apparently in justification. He should clearly understand that the conduct of a man who slanders his colleague from behind the shield of anonymity is without the pale of forgiveness by every one of his professional brethren who place honor before material gain; and anything that he may say in extenuation of his gross breach, not only of etiquette, but of morals, will only intensify the feeling with which his act is generally regarded." These are no doubtful utterances; and the gentleman has clearly been guilty of conduct which the medical profession unsparingly condemns. But both are Fellows of the Royal College of Physicians; and the College guarantees the behavior of its Fellows and members towards each other. To be sure, it cannot—being fallible, like all other human institutions—always secure good conduct from its Fellows, sad to say. But a great parade is made of withholding the Fellowship from sundry men for unprofessional conduct (under which pretext a good many men are injured who have not been guilty of any unprofessional conduct); and much is said about its watching over the behavior of its members and Fellows. It now remains to be seen what the College will do.

Some scandals occurred a few years ago in which a well-known medical baronet not only broke its rules, but actually snapped his fingers at the College afterwards, apparently with impunity. But then he was such a big fish! Now that the culprit is not quite such a whale, it will be curious to see how the old

lady will proceed to deal with him. If he escapes without chiding, or, indeed, some more substantial mark of her wrath, then the rule about guaranteeing conduct had better have "obsolete" written across it, and all talk about "withholding the Fellowship for unprofessional conduct" be relegated to the charnel-house of the dead past, the only place for it in that case. One cannot but sympathize with the censors brought face to face with such an unpleasant affair. It is so delightfully easy to keep a man out of the sacred order if several of the august personages who rule the roost only choose to do so. But how about any energetic action when the culprit is in?

The College has held a meeting and decided "to take such steps as they think needful." The medical world looks on patiently to see what the needful steps are. Instead of action *in camera*, the censors must act in the open light of day, within the sight of the public. A subject of no little interest to the psychologist is thus afforded to him. It is to be devoutly hoped that the authorities will this time show the medical world that they can act upon occasion; for a more flagrant instance of insubordination can scarcely be required for them to do something. It is high time that the censors remember the dignity of the College and what is owing to public opinion, and to demonstrate to the world at large that its rules can be operative. The College has great capacity in petty matters. Perhaps it has more backbone than its mockers give it credit for. Sir William Jenner, the President, is a man who holds the chieftainship of the medical profession without a dissentient voice, and every one has the utmost confidence in him. But the President cannot transform all the elements of the College into men who dare act openly, and it is by no means absolutely certain that all the fifteen units of the Censors' Board can be elevated to his standard. It is certain—as certain as anything can be in a finite world—that this scandal will not improve the position of the profession in the eyes of those who hold it cheap,—a considerable section. It is equally certain that "the unfortunate manner in which the paper was put together" will be utilized by the anti-scientific portion of the public, known as the anti-vivisectionist party, to the utmost. The most will be made of the patient's allusion to "his wife and family," and of the symptoms which the sodium nitrite produced. A grand dish will be served up out of these materials, on which the party can feast sumptuously. And there is a large and comparatively compact body of the public who never miss an opportunity of decrying orthodox medicine. They are dissenters in religion, and radicals in politics. They hate meat and drink, are vegetarians and teetotallers. They speak of medicine as "allopathy," and have unbounded

faith in globules. They detest Jenner's discovery of the value of vaccination, which they hold at once to be useless as a protective against smallpox, and the vehicle for communicating disease. This active, mischievous body will seize upon the subject and gloat over it with an exquisite sense of enjoyment. Leicester will mock. Leicester has set its face against vaccination sternly, uncompromisingly; just as Keighley did some years ago, till a sharp outbreak of smallpox taught the natives a thing or two they either did not know or did not choose to acknowledge. Recently one of the infidels as to vaccination was sent to prison, and the people made him a martyr. When he emerged from the portals of his prison he was a hero who received a grand ovation, instead of a silly fellow who deserved all he had got. And now there is disorder and almost riot among the stocking-weavers, who, of course, only know what their leaders choose to tell them. As to the great facts, they shut their eyes to them. As to straining at the gnat and swallowing the camel, no Pharisee of old could give the anti-vaccinationists points. They see in vaccination a means of spreading disease, which is lucrative to the medical profession, who consequently uphold it. To all those and such like this affair will furnish grand matter for declamation and scorn. Knowledge may come to a stand-still; medicine may become as static and non-progressive as the pyramids of Egypt or the pillars of Baalbec. What care they? If they prefer smallpox to vaccination, why should they not in a free country? The right of private judgment is the great feature of Protestantism, and Leicester has advanced far beyond Protestantism. If they choose to have smallpox, why should they not? Certainly, and cultivate the malady till it becomes dangerous even to their vaccinated neighbors! But if your neighbor does not care about the risk, how then? Well, kick up a row till he thinks smallpox the lesser evil of the two. It is a solution of the difficulty, certainly.

In the North country there is a saying to this effect: "It takes one of all sorts to make a world." It certainly does. But an ignorant Leicester stocking-weaver howling for smallpox and abusing the medical profession is scarcely so sad a spectacle as that of one Fellow of the Royal College of Physicians stepping out under a pseudonyme to poniard a colleague in the dark. The profession whose "good name" this champion so chivalrously upheld had, indeed, better look to its custodians. If these Fellows of the College cannot act with a little more sense of propriety, some more care of what is due to a professional brother, the poor stocking-weaver may well point the finger of scorn at medicine. Let the College act with dignity, and then those whose conduct needs some guarantee in order to be decorous, if not decent, will go

in real fear of it. Continenence is not chastity. Virtue has a shifting value. One man may behave himself from self-respect, another only because he fears the penalty if he should fail. But when a man steps out of his way to stab a professional brother, not to say a colleague, then the offence is one which carries with it no extenuating circumstances. It is not a venial lapse; it is the commission of a sin. If the College cannot act in this case, then men who only behave well under the penalty will feel at liberty to act according to their inner promptings. A strong, vigorous action on the part of the College would reinstate it in the opinion of the profession, and possibly, too, in that of the public. Not that all shortcomings in the past should be atoned for by unmeasured severity in this particular instance: no reasonable person wishes that. What is to be desired is that the governing body will do something to show that its canons are not to be outraged with immunity from consequences. If unprofessional conduct has to be punished by withholding the Fellowship from offenders, surely such conduct in a Fellow ought to meet with appropriate recognition. If Fellows of the College are allowed to set a bad example unproved, others will be tempted to follow; for it is desperately easy for a weak man to follow a bad example. The profession has its reputation to maintain, and may, apparently, thank its stars that it has not to make it. It looks as if it would take it all its time to uphold what others have won. What action the College will take in this emergency waits to be seen; but the eye of the world is upon it.

J. MILNER FOTHERGILL.

CHARLATAN.—The *Apotheker Zeitung* gives the origin of this word as follows: In the olden time, when the doctors, sitting in their studies, weighed the ills of their fellow-man, and searched the depths of nature for remedies, they were not in the habit of riding about; their homes were hospitals, and they did not leave their patients. At that time a genius of a doctor, who knew more about calculating for himself than medicine, made his appearance in Paris. His name was Latan. He procured a small one-horse wagon (*char*), upon which he packed his remedies for all possible affections. With these he drove through the streets of Paris, crying out his wares and looking for patients. He was the first driving doctor, and soon became renowned. Whenever he came along, the populace greeted him with, "Voilà le char de Latan." This was soon abbreviated to "Charlatan," which, at that time, denoted a driving doctor.—*Weekly Drug News*.

CODEINE PHOSPHATE has been prepared by Merck, at the suggestion of Prof. Hegar. It is soluble in four parts of water, and is suited for hypodermic injection.

PROCEEDINGS OF SOCIETIES.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

STATED MEETING, DECEMBER 6, 1883.

The PRESIDENT, R. A. CLEEMANN, M.D., in the chair.

DR. W. GOODELL exhibited

TWO CYSTS OF THE PAROVARIVM.

In commenting upon these specimens, he remarked that both patients got well; he, indeed, had never lost a patient from whom he had removed a parovarian cyst. In both cases, a correct diagnosis was made previous to the operation. One interesting diagnostic point was the complete absence of the *facies ovariana*. The color in the cheeks was good, and the countenance was free from the anxious expression present in cases of ovarian tumor. One tumor had existed for ten years, the other for one. Another important point in the differential diagnosis is not only the flaccidity of the tumor, but its variable degrees of flaccidity. Upon inspection, it is seen to reach to the sternum, and seems to occupy a large portion of the abdominal cavity, but, when the hands are placed upon its sternal edge, it can be compressed to the level of the umbilicus. An ovarian cyst, on the contrary, is hard and incompressible. Exceptions to this rule are very rare,—that is, either a tense parovarian cyst or a flaccid ovarian one. A third important distinguishing point is the long time—ten years in one case—which the tumor existed, and, further, without marked deterioration of health. After being tapped, these tumors usually refill, but occasionally they do not, and a cure is thus brought about. The fluid withdrawn has been in every case limpid, and generally colorless, but it has sometimes had in his experience an emerald tint. These tumors are generally free from serious adhesions, but if in an operation for the removal of one, adhesions should exist, where for any reason their forcible separation would be inadvisable, or the cyst were intra-ligamentous, he would not hesitate to leave the adherent portion of the cyst-wall, or the whole cyst itself, after making a big hole in it, as the fluid it secretes is bland and unirritating to the peritoneum.

Any one examining one of these cysts for the first time would consider it to be of ovarian origin; for it is only by patient search that the ovary can be found spread out over the cyst-wall. The microscope will decide with certainty in any otherwise doubtful case. The tumor is covered with a beautiful net-work of veins.

When a cyst of the parovarium exists on one side, the ovary of the opposite side is usually found to be diseased, and should be

removed. In these cases, the remaining ovary was seen to be enlarged, and the site of a small ruptured cyst was pointed out. The Fallopian tube was also enlarged, and the terminal vesicle of the Fallopian tube, or the hydatid of Morgagni, was enlarged and cystic. This vesicle sometimes attains the size of an orange, and often ruptures spontaneously without any bad effects. A few years ago, one of these small cysts ruptured while he was making an examination of the patient to ascertain its character.

Dr. GOODELL exhibited a

CANCEROUS WOMB REMOVED PER VAGINAM.

In view of the very fatal statistics of the operation for the removal of the womb for the radical cure of uterine cancer, he had hesitated to perform it. In most of the cases where the disease had been seen early enough by him to give a chance of success, the patient had been unwilling to take the risk. On one occasion, when every preparation had been made to operate, the patient had a convulsion, and an examination of the urine showed a high proportion of albumen, in consequence of which he refused to operate. About a month ago, Dr. Charles A. Dulles called him in consultation to see a patient in whom the carcinomatous condition was limited to the anterior lip. The womb was movable. The case was put frankly before the patient, and all its dangers were pointed out. The choice of operations being given to her, she decided, after due consideration, to take the risks of the radical one. The operation was not as difficult as he anticipated.

The first step in the operation was to scrape away all cancerous tissue and to sear the remaining surface with Paquelin's cautery. The vagina was then thoroughly cleansed. A stout thread was passed through the cervix, to draw down the womb, instead of using a volsellum, the handles of which would be in the way. A circular incision was made around the cervix, and the tissues were stripped up anteriorly and posteriorly to the reflection of the peritoneum, and laterally to the insertion of the broad ligaments. Finally, the peritoneum was opened and the womb retroverted into the vagina by means of the obstetric crochet passed over the fundus. A strong thread was now passed through the body of the uterus, by means of which to manipulate it more easily. A ligature was now passed around the broad ligament of the right side and secured it *en masse*, and a second double ligature was passed through it and tied on opposite sides. This side of the broad ligament was then divided, the uterus drawn down, and the ligament of the left side secured in a similar manner and divided. The vaginal wound was closed and dressed with iodoform and cotton. A frank peritonitis set in on the third day, and proved fatal on the fourth. The result made him doubtful whether the

operation is a legitimate one; he, indeed, felt disposed to avoid it whenever possible.

Dr. E. E. MONTGOMERY inquired about the feasibility of using the galvanic-wire *écraseur* to divide the broad ligament, keeping the wire at a low red heat and dividing the tissues slowly, and avoiding the necessity for a drainage-tube. Another method which he had been revolving in his mind was by means of the galvanic knife to dissect out the uterus, leaving the peritoneum intact, thus imitating to a certain extent the operation of Dr. Marion Sims of scraping and the use of zinc chloride.

Dr. GOODELL thought that Dr. Montgomery's galvanic wire would get too hot as the loop became small, and would then divide rapidly like a knife, and incur the danger of secondary hemorrhage. He fears that the steam generated by the hot wire would penetrate the peritoneal cavity and have an irritating effect. He has a galvano-cautery battery, but has not used it since the introduction of Paquelin's benzoline cautery, as he finds the latter far more handy and manageable. He thinks Dr. Montgomery's suggestion of shelling out the uterus a very good one.

SPECIMENS FROM A CASE OF BATTEY'S OPERATION.

Dr. MONTGOMERY exhibited, through the courtesy of Dr. W. H. Warder, the uterine appendages which had been removed from a young lady for the relief of dysmenorrhœa which had resulted in physical and mental failure. Menstruation had commenced at the age of fourteen years, had always been painful, and had developed hysterical manifestations. Bathing at the sea-shore had at one time stopped the periods for three months; after this her health failed, her mind had been seriously affected for the last three years, and she would run away or do herself some violence at the menstrual periods if not closely watched.

Examination.—The uterus was enlarged and tender; there was profuse leucorrhœa. The os uteri was dilated, and the uterine cavity scraped and cauterized with carbolic acid, and bromides, etc., used internally, but no improvement resulted. The ovaries were removed to-day through abdominal section; catgut ligatures were used. The ovaries are very much enlarged, and contain small cysts. The abdominal wound was closed with silk sutures, and covered with an impervious dressing of collodion, cotton, etc.

HYSTERO-EPILEPSY AS A COMPLICATION OF PREGNANCY.

Dr. WILLIAM H. SHIPPS, of Bordentown, New Jersey, sent the following contribution:

Briefly defined, hystero-epilepsy is a term applied to an abnormal neurotic condition in which are manifested certain phenomena characteristic both of hysteria and of epilepsy. Out of two hundred and seventy-six patients

confined at La Salpêtrière Hospital, Paris, under treatment for various nervous affections, thirty-two were diagnosticated by Beau, a careful observer, as suffering from this disease. Among this number the malady assumed either a distinct or a combined form: hence he very wisely groups the cases into two classes. In the first, the hysterical seizures and epileptic fits remain distinct one from the other; to this form he adapts the term given by Landouzy, and designates it as hystero-epilepsy with distinct crises.

In the second class, and the one of which this article furnishes an illustration, the hysterical and epileptic seizures are coeval, both developing at the same time: to this form the name of hystero-epilepsy with combined crises has been given. The object of this paper is not to enter into a consideration of the disease as it is met with in general practice, but simply to examine it as a complication of pregnancy, a stand-point from which, fortunately, we are rarely called to view it.

During the early part of March, 1883, I was called to attend a woman said to be in a fit. Arriving at the house, I found, lying on a bed, a young woman, apparently seventeen or eighteen years of age, of fairly-vigorous physique, who was striving against the united efforts of two or three neighbors who sought to prevent her doing herself bodily harm in the violence of her struggles. Examination showed entire loss of consciousness, eyes open and staring, pupils widely dilated, frothing at the mouth, which was then tightly closed, pulse full and bounding. Inquiry elicited that during the day she had been visiting a friend herself the subject of some spasmodic affection, and whilst in her company became greatly exercised on some trivial occurrence, and in this state of excitement returned home, which place she no sooner reached than she was seized with a convulsion. Her husband informed me that she was in the third month of pregnancy, and that prior to this morning she had on one or two occasions attacks somewhat similar, though of less severity. I at once injected hypodermically one-third grain of morphine, which in a short time was followed by a total disappearance of all spasmodic action, a state of stupor supervening, from which in the course of three or four hours she aroused apparently well as ever. On the day following I was called to see her, and found her in a state of high nervous excitement, sobbing, and deploring the presence of some impending danger which she, in her imagination, insisted was threatening her. In a short time the stage of muscular contraction, loss of consciousness, stupor, etc., took the place of the hysterical symptoms, finally terminating, as before, in a return to her normal condition.

Without attempting to follow the case step by step, taking in all its details, and noting the many and peculiar phases through which

it passed, it is interesting to note that prior to September 23, 1883, covering a period of two hundred days, not a day passed without the occurrence of one or more paroxysms. At times the hysterical phenomena would be most marked and usher in the attack; then, again, the epileptic fit would take the precedence, always, however, accompanied by the undeniable imprint of the dual disease hystero-epilepsy. In the inter-paroxysmal period she enjoyed for the most part average good health.

On the morning of September 23 I was asked to see her in an attack of more than usual gravity. When I reached the house, she was profoundly unconscious and had been so for several hours. The time for her approaching labor being near, I made a vaginal examination, but found no evidence of commencing uterine action. I ordered a hot mustard-bath, mustard to the extremities, and bromides the moment she should be able to swallow. In the evening, when I again called, her condition was apparently unchanged. I then ordered a blister to the nape of the neck, and left the patient, to return early in the morning. At 7 A.M. a messenger called, stating that the woman was now perfectly rational and to all appearance in labor. I at once responded, and found that she was having bearing-down pains of moderate intensity at intervals of five or ten minutes, mouth of womb dilating, vertex presenting. I remained by the woman's side until 3.45 P.M., when the child, a healthy female, weighing nine or ten pounds, was born. The labor did not differ from ordinary labors, except that it was only by the utmost vigilance that the woman was prevented falling into one of her accustomed attacks. After the birth of the child, I gave it to the mother, at the same time remarking to her that, as she valued the life of the child, under no circumstances was she to allow herself to have another convulsion. She promised faithful obedience, and up to the present has not shown the first indication of her old trouble. It should be mentioned that during the entire period the patient was under observation she had daily taken large doses of the bromides and other nervines without any effect, save, perhaps, in ameliorating the number and violence of the paroxysms. The case is interesting on account of the rarity of the disease as a complication of pregnancy, its persistence throughout the entire period, its resistance to all remedial measures, and the final disappearance of all symptoms after the termination of labor.

Two queries very naturally present themselves: What was the exciting cause of the attacks? Would the induction of premature labor in this and similar cases be justifiable?

In answer to the first query, I attribute the attacks to an action upon the brain and spinal cord, reflex in its nature and developed or excited by the fœtus in utero.

The happy termination of the case would seemingly offer a negative to the second query; but better judgment will, I think, suggest the wisdom of the operation, and the danger of refusing to employ what, theoretically at least, offers the only chance of relief: at all events, in a similar case I would most certainly have recourse to the operation and expect from it the best results.

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting was held December 6, 1883, FORDYCE BARKER, M.D., LL.D., President, in the chair.

Dr. T. GAILLARD THOMAS read a paper on THE PREVENTION AND TREATMENT OF PUERPERAL SEPTICÆMIA.

The author's reason for preparing a paper on this subject was that since relating briefly the history of a case of puerperal septicæmia treated by intra-uterine injections at one of the societies within a comparatively recent period, he had received many inquiries concerning the mode of treatment, and also because the subject had not been fully elaborated in any single essay, and it was one which, in the light of our present knowledge of antiseptic methods, deserved special consideration. At the annual meeting of the American Gynæcological Society at Baltimore, Dr. Thomas stood alone, with a single exception, in the advocacy of intra-uterine antiseptic injections in puerperal septicæmia. He was one of the first who adopted the method, together with cutaneous refrigeration, in this affection. Dr. Thomas made brief reference to the different views entertained concerning the nature of puerperal fever,—those which considered it a fever due to suppression of the lochia, inflammation of the womb, of the peritoneum, a specific puerperal fever, uterine wounds, arrest of milk-formation, etc. The blood of the puerperal woman is favorable to the development of thrombi and of sepsis, the nervous system is in a state of excessive sensibility, and there are local conditions favoring the development of conditions classed as puerperal fever. The inner surface of the uterus, just after delivery, presents an unhealthy diphtheritic appearance, barring the exudation; there is an irregular, raw, placental site, with small clots covering the uterine sinuses, there is a disagreeable odor, and there are, perhaps, slight lacerations on the cervix, along the vagina, or at the outlet. The secretions along this canal, if inoculated into the finger, would produce irritation and lymphadenitis, but not erysipelas or angioleucitis. Notwithstanding this condition, recovery is almost universal after parturition. But now and then some poison enters through the lesions in the genital canal which act as rapidly and decidedly upon the general system as does a little yeast added to dough, and alarm-

ing phenomena develop, which, if left unchecked, lead to a fatal issue. The physician at his visit in the morning leaves the patient in a favorable condition, with a normal pulse and temperature, but returning a few hours later he finds her complaining of a slight chill, pelvic pain, the lochia have ceased, the milk-secretion is checked, and, as the symptoms proceed, the patient complains of headache, wears an expression of indescribable anxiety, the pulse runs up perhaps to 120, and the temperature to 103° or 104° F. If the physician contents himself with the idea that the patient is simply suffering from milk fever or with malarial symptoms, and does not recognize the fact that poison is being absorbed constantly into the general circulation from some solution of continuity in the genital tract, the active lymphatics will continue to take up the poison, lymphangitis develops, cellulitis, peritonitis perhaps, and all that group of conditions classed as puerperal fever, terminating in death.

As to the pathology of the condition, it is essentially puerperal septicæmia. It may assume the form of a phlebitis, cellulitis, lymphangitis, or a peritonitis, but the disorder is due to the absorption of poison into the circulation of the puerperal woman at some solution of continuity in the tract of the genital canal. As to nomenclature, he disapproved of the term "metria" proposed by the Dublin school of midwifery, considering it more objectionable than the term puerperal fever. Puerperal septicæmia, however, conveys a definite and clear conception of the true nature of the disorder, although in many respects it is far from being a satisfactory designation. As to the exact nature of the poison, German pathologists have tried to ascribe it to the round-formed micrococci, but in such a paper as the present one the recent view of the nature of certain diseases as dependent upon bacteria could not, for evident reasons, be considered. But, admitting that some toxic agent may be the cause of the affection, we should inquire as to what are the best methods for preventing its entrance into the system, and, should it once gain entrance, study to know the best methods for counteracting its influence or destroying its activity.

There are two methods by which the poison could gain entrance to the genital tract,—namely, by the air, and by direct contact through the clothing of the hands of the surgeon or nurse, the sponges, instruments, etc. The author then directed his remarks specially to private practice, where, even in the wealthiest families, there is a carelessness shown which amounts almost to criminality. The greatest of care should be taken in every case of midwifery to guard against the entrance of septic poison into the circulation.

He enumerated the following prophylactic

measures which it seemed to him should be adopted in every case of midwifery, whether in hospital or private practice.

1. The room in which the confinement is to take place should have the floor and the walls thoroughly washed with a solution of carbolic acid or of the bichloride of mercury. All cloths and towels should be washed in the same solution, and all curtains and drapery should be dispensed with.

2. The nurse and the physician should take care that all clothing, both under and outer, is free from any effluvia of septic affections, as of typhus, scarlet fever, erysipelas, and the like, and, if so exposed, they should change every article of clothing, and bathe the entire body, especially the hair and beard, with an antiseptic solution, as of boracic acid.

3. As labor comes on, the nurse should thoroughly wash her hands and cleanse the nails with a stiff brush. She should give a vaginal injection of an antiseptic solution every four hours during labor, and keep a cloth wrung out of the same solution over the vulva.

4. Both the physician and the nurse, before approaching the genital organs of the woman, should thoroughly wash the hands and nails with soap and water and soak the hands in a bichloride solution (one to one thousand).

5. The first two stages accomplished, the third stage should be efficiently produced. All portions of placenta and membranes should be removed, and ergot administered in moderate doses three times a day, and kept up for a week, in order to secure complete expulsion of clots and closure of the uterine sinuses.

6. The doctor should satisfy himself, without taking the word of the nurse, at the conclusion of labor, as to the exact condition of the genital tract, and, if he find a laceration of the perineum, close it by suture; and if slight solutions of continuity be found on the vulva and vagina, they should be dried with a cloth and touched with equal parts of persulphate of iron and a saturated solution of carbolic acid, again dried thoroughly with a cloth, and painted over with gutta-percha collodion. In this way absorption would be prevented for three or four days, when the application could readily be repeated.

7. Six or eight hours after labor, the patient having become rested, the vagina should be syringed out with an antiseptic solution, and a suppository of cacao-butter, containing from three to five grains of iodoform, be introduced.

8. The vaginal injections and suppositories should, in all cases of normal labor, be repeated every eight hours, and, in cases of difficult or instrumental labor, twice as often, and should be kept up at least ten days; the nurse observing the precaution already mentioned,—to wash the hands in a disinfectant solution before every approach to the genital tract of the patient.

9. When the use of a catheter becomes necessary, the physician should employ a gum-elastic catheter, which should, before use, be thoroughly immersed in the antiseptic solution. The nurse should not be allowed to employ an old silver catheter which she has probably carried about for several years.

10. Last, but by no means least, let the physician inform himself, by personal observation, as to the competency of the nurse to syringe out the vagina thoroughly and to place the antiseptic suppositories just where they should be placed, and to use the catheter without injury to the patient. By neglecting these precautions there might be failure to wash out the upper segment of the vagina while the lower was thoroughly washed. The trouble involved in this plan would not be at all great, when measured with the comfort given the mind of the physician from a feeling that he had done his whole duty. Every woman in confinement ought to be treated as though she were going through a capital operation, and, if the rules laid down were conscientiously observed, many households would probably be saved the sorrow of losing their female heads.

With regard to the use of intra-uterine injections as a prophylactic resource, Dr. Thomas said that it could not be approved of, except in very severe operations within the uterine cavity, which render the occurrence of septicæmia almost certain. As a preventive measure to be uniformly adopted, he looked upon it as in the highest degree rash and reprehensible.

Supposing that the poison has entered the system, what are the best means now known for stopping the septic process?

First. As soon as a diagnosis of septicæmia is determined upon, all pain and nervous perturbation should be checked, and mental anxiety should be quieted by the hypodermic administration of Magendie's solution of morphine, unless some special idiosyncrasy against opium exist; and during the entire attack, whenever suffering of body or mind occurs, it should be repeated; perhaps once in six or eight hours would prove sufficiently often. No other method can compare with the hypodermic in these cases. If a sharp and new needle be used, and thoroughly cleansed with soap and water and dipped in the bichloride solution each time of use, no abscesses will occur.

2. The patient having been entirely relieved of pain, the nurse should quietly, without any hurry, noise, or disturbance, spread an oil-cloth over the edge of the bed, made to fall into a tub of warm water rendered antiseptic by a two or two-and-a-half per cent. solution of carbolic acid, or the bichloride solution, one to two thousand. Then a Chamberlain's glass tube, the perforations confined principally to the end, or Lyman's tube, should be fitted to a Davidson's syringe,

immersed in the tub of water, the tube conducted carefully through the vulva up to the fundus of the uterus, with the index finger as a guide, and a stream of water be made to flow against the uterine wall, washing away the blood-clots or other foreign material that may be present. In some cases, in which there was reason to suspect the presence of portions of membranes, the patient had been chloroformed, and the hand passed carefully into the uterus and the walls very gently curetted by the nails. In some cases, the walls might be rubbed down with a sponge.

The dangers of the method are, first, the introduction of air into the uterine sinuses; secondly, the production of hemorrhage by detaching thrombi, which fill the mouths of the uterine sinuses; thirdly, the forcing of some of the fluid directly into the circulation; fourthly, the production of grave convulsions by the sudden and powerful influence upon the nervous system; and, fifthly, the passage of fluid through the Fallopian tubes. But all these dangers may be avoided by care as to details, and the use of a large tube, and of water of not less than 100° F. The tube should not quite fill the os internum or externum and exclude the exit of the water. If necessary, dilate by the finger or Barnes's dilator. Have a solution of persulphate of iron always at hand, in case of sudden hemorrhage; and he further advised, in case hemorrhage should occur, to give ergot, make pressure so as to cause contraction of the uterus, etc.

The frequency of the intra-uterine injections will vary greatly in different cases. In a mild case, in which the temperature readily comes down, it might be necessary to use the injection only once every five hours, in other cases every three hours, and in bad cases every hour. The injections should always be administered by the physician, and always be carried fully up to the fundus of the uterus. Many prefer the use of a syringe which carries a steady stream by gravitation, as the so-called fountain-syringe, and such, formerly, was the author's preference; but he had since learned that, with care, the stream can be projected with gentle force without danger, and more effectually bring away any clots and material that may be present in the cavity of the uterus. Some prefer continuous irrigation, but he looks upon it as a delusion and a snare. For vaginal irrigation, however, it is an excellent method. Nevertheless, in very severe cases, he prefers the continuous flow with the intermittent current, used every three hours, rather than to subject the patient to the use of the intermittent current as often as it would otherwise seem necessary.

3. The uterus having been thoroughly cleansed, and the patient entirely quieted, attention should be turned towards controlling the temperature. Formerly he had relied on

cold or tepid water, the patient lying on Kibbie's cot; but at present he accomplishes the same result more easily and pleasantly by the use of Townsend's rubber-tube coil, which covers the whole of the abdomen from the ensiform cartilage to the symphysis pubis, through which a stream of cold water passes by means of siphon-pressure, the vessel of supply being about three feet above the level of the patient, and the receiving-vessel being upon the floor. By this means a temperature of 104° could be brought down and kept at 100° F. without difficulty. In his service at the Women's Hospital the rubber coil is as commonly in use in cases of laparotomy as gargles are in sore throat. Sometimes the temperature would not go down inside of twenty-four hours. He had never seen any evil result from the use of the coil.

4. The nervous system should be placed under the influence of febrifuge medicines, as of quinine, or capsules of Warburg's tincture as recommended by Dr. Metcalfe, or salicylate of soda.

5. The patient should receive fluid food frequently repeated, milk being the staple article, and animal broths for a change.

6. The attendant should surround himself with abundant and efficient assistance. The physician should associate with himself some young practitioner who can use the douche safely and efficiently, and there should be at least two nurses, the one to relieve the other.

The antiseptics which had been employed were thymol, boracic acid, salicylic acid, carbolic acid, and mercurial bichloride. Of these all others had disappeared under the superior excellence of the last two, and carbolic acid appeared to be about to be abolished for the bichloride in the strength of one part to one or two thousand. If carbolic acid be used, it is not safe to carry the strength beyond two or two and a half per cent.

DISCUSSION.

Dr. W. M. POLK, having been requested to open the discussion, said that he believed that he uttered the thought of every member of the Academy when he said that they were deeply indebted to Dr. Thomas for the able and even eloquent presentation of this most important subject. The author had gone into the subject so thoroughly that there seemed but little left to say, especially with reference to treatment. He thought that perhaps it would have been better, in view of the stress which Dr. Thomas had placed upon antiseptic treatment, which most would of course accept, had he placed himself more squarely upon that pathological view which regards puerperal fever as identical with septicæmia and pyæmia. So long as there is any question on this point will there be doubt in the minds of many with regard to the propriety of many measures advocated by Dr. Thomas. Dr.

Polk regarded the disease, as the question at present stood, as identical with septicæmia and pyæmia. The difference in the symptoms was merely that that belonged to the peculiar tissue involved and peculiar condition of the circulatory fluids. As to treatment, standing as he did upon this basis of septicæmia and pyæmia, it seemed to him that the principles of Listerism, as laid down by Mr. Lister and his followers, and so ably advocated by Dr. Thomas to-night, entirely covered the ground. As to precautionary measures, there was absolutely nothing to add, unless it were that attention should be paid to the purity of the atmosphere, especially in this city. Regarding active treatment, he would simply say that oftentimes, in his experience, he found himself making use of intra-uterine injections when in reality the sole lesion which was killing the patient was to be found in the cervix. This was found in a sloughing condition, and the weight of the fluid failed to separate the lips properly and effect cleansing. He therefore now makes a careful examination of the vaginal canal, introduces the Sims speculum, draws down the cervix with the tenaculum, and, if he finds any lesion, applies directly to the spot a strong solution of carbolic acid or other disinfectant; in many cases this is the only treatment which seems necessary. He had sometimes introduced Skene's blunt curette and removed, with great gentleness, any remaining membranes from the uterine cavity.

Dr. J. B. HUNTER had experienced the difficulties of making intra-uterine injections, and thought it should never be intrusted to a nurse. It should be done with the greatest gentleness and with the least disturbance to the patient, and he believes it unnecessary to lift the patient to the edge of the bed at all, but to use a large bed-pan and make the injections while she lies on the back. The Chamberlain tube is usually too large, especially after the first few injections, as the cervix then contracts more or less. The perforations should not extend down upon the instrument, else all the fluid may escape into the lower portion of the canal. There is apt to be more objection against the proposed methods on the part of friends and the nurses than on the part of the patient. He uses water of a temperature of 110° F. The bodily temperature should be a guide as to the frequency of the injections. He did not approve of the coil in cases of puerperal fever, for the temperature might thus be reduced while septic material was still being absorbed, and thus mislead the physician. The coil, however, is a most excellent instrument in peritonitis after laparotomy.

Dr. E. L. PARTRIDGE thought that there could not be much difference of opinion in the minds of those who had seen much obstetric practice concerning the pathology of the condition. He would lay special impor-

tance upon personal cleanliness on the part of the physician and nurse, as prophylactic measures. As to the management of puerperal septicæmia, he made use of intra-uterine injections with the same frequency recommended by Dr. Thomas and others. With reference to agents employed, he would only speak of a supplementary measure to the intra-uterine injection introduced by the late Dr. Livingston at the Nursery and Child's Hospital; that is, the injection of a mixture of iodoform and glycerin after the douche.

This measure seemed to render the necessity for the douche less frequent. He recognized the value of the bichloride solution, and also that of the coil in cases of puerperal septicæmia, for the purpose of reducing temperature. Its first application had produced no greater discomfort than the first rectal injection.

THE PRESIDENT said that, on account of the lateness of the hour, it would be impossible for all the gentlemen prominent in this specialty to take part in the discussion, and, as the opinion of all should, as far as possible, be obtained, he would suggest that the first meeting in February be appointed as the time for the special consideration of the subject of the paper, and he would beg to be allowed to open the discussion on that occasion. Some years ago he had given expression to views on this subject which were not in accord with those of any of the gentlemen present on that occasion, but which, he believed, were the views entertained by many prominent gentlemen throughout the world at the present day. He should agree with the author of the paper as to the description given of puerperal fever, but as to the sum total of the conditions which went to make up the pathology he should differ, and also with reference to certain matters in treatment.

NEW YORK PATHOLOGICAL SOCIETY.

A STATED meeting was held December 12, 1883, GEORGE F. SHRADY, M.D., President, in the chair.

ANOMALIES IN THE DEVELOPMENT OF THE LIVER.

Dr. FERGUSON presented some specimens of anomalous development of the liver, the most important form, probably, being that in which the right lobe attained an unusual size, reaching down to the crest of the ilium, club-shaped, and constituting an apparent abnormal tumor, liable to mislead the diagnostician. Moreover, it might cause difficulty by pressure upon the colon and ureter, interfering with the function of these organs. The left lobe was likely to be small in size.

The second in importance was that form of anomaly in which the left lobe was largely increased in size, while the right was likely to

be diminished. This form also was liable to mislead the diagnostician, who might suppose that he had to deal with a new growth.

The next form was that in which but one lobe of the liver was present. Dr. Ferguson had seen but a single specimen of this description. In it the liver was almost a complete hemisphere.

The next form was that in which the liver was composed of one large lobe with a few—perhaps four—small nodules on its under-surface.

Still another form of anomaly was that in which the liver, consisting of one large lobe, was cut up by a large number of grooves, as it were, constituting numerous small nodules. One of the specimens presented probably contained as many as thirty-five or forty of these small nodules. It was to be remarked that the specimens mentioned were normal, or nearly normal, in structure, and that the anomalous form was not due to disease.

Dr. Ferguson also presented specimens removed from a patient with the following history. The patient, houseworker, was 22 years of age, married, who entered the hospital on the 27th of November, 1883. A few hours previous to admission she had been suddenly seized with acute pain in the chest, dyspnœa, and vomiting. She had for some time before been in a hospital and treated for dropsy. On admission, the face was cyanosed, there was severe pain in the chest, there was a loud blowing murmur over the base of the heart, dyspnœa, rapid respiration. The urine contained albumen. The temperature was not at any time very high. Death took place inside of twenty-four hours. Autopsy showed œdema of the legs below the knees, twelve ounces of serum in the peritoneum, no evidence of peritonitis, a few ounces of fluid in the pleural sac, extensive vegetations on the mitral valve, dilatation of the corresponding ventricle and auricle, lungs intensely œdematous and congested, fatty degeneration of the liver; enlarged, congested, and pigmented spleen; left kidney slightly larger than normal, the right much atrophied; the ovaries displaced and fixed by adhesions; the Fallopian tubes contained purulent fluid, the right about two ounces and the left a smaller quantity. Microscopical examination showed ciliated and columnar epithelium, pathological properties which Dr. Ferguson had never witnessed in any other form of abdominal cyst.

Dr. GARRISH asked Dr. Ferguson if, out of the thousand autopsies which he had made, he had found any case of cirrhosis of the liver in which there was absence of an alcoholic history.

Dr. FERGUSON said that the question was a very difficult one to answer, for the reason that it was almost impossible to get a straight history regarding alcoholic beverages; he thought, however, that he had seen at least

two or three cases of cirrhosis of the liver in which there was positively no alcoholic history.

Dr. CARPENTER remarked that it was an accepted fact that cirrhosis of the liver might occur aside from alcohol as a cause.

DERMOID CYST DISCHARGING INTO THE PELVIS OF THE KIDNEY.

Dr. CHARLES HEITZMAN presented a specimen of urine, which was brought to him about a year ago by a physician in the central part of the State, who stated that the woman who passed it was about 50 years of age, and was in the habit of passing urine containing a large amount of whitish threads, every two to four weeks, under excruciating pain. The specimen brought to Dr. Heitzman had a glassy, shining appearance, contained floc-cules, and, under the microscope, showed the characteristic properties of a dermoid cyst,—horny, dry epithelial substance, and crystals of urate of soda in sheath-form. Dr. Heitzman diagnosed a dermoid cyst which at certain periods discharged its contents into the pelvis of the kidney, and advised an operation. He heard nothing more of the case until recently, when the physician wrote him that the patient had continued to pass urine of a similar appearance under similar conditions about once in two or three weeks; that she was otherwise in good health, excepting laryngitis.

REMOVAL OF ENLARGED THYROID GLAND BY ELASTIC LIGATURE.

Dr. J. A. WYETH presented a part of the isthmus of an enlarged thyroid gland which had been successfully removed by the elastic ligature after failure, resulting in hemorrhage, with the ordinary ligature.

ANGIOMA OF THE VOCAL CORD.

Dr. LOUIS ELSBERG presented the specimen, which had recently been removed from a man, 28 years of age, a vocal teacher, formerly a lecturer. The tumor was situated on the right vocal band, near the anterior commissure, and, in the mirror, appeared the size of a large pea. Under the microscope it presented the characteristics of an angiomatous tumor. Such tumors were frequently met with in the skin, but this was about the tenth occurring in the larynx which had been recorded in literature. He himself had presented another to the Society about three years ago. They usually occurred on the right vocal band.

PUERPERAL TETANUS.—A case of fatal puerperal tetanus, occurring at the Lying-In Hospital in Prague, is reported in the *Sz. Louis Courier of Medicine* for December. The tetanus began a week after delivery, and terminated in death five days later. The autopsy showed metritis and pachymeningitis spinalis et cerebri.

GLEANINGS FROM EXCHANGES.

PHARMACY, THERAPEUTICS, AND COLLECTIVE INVESTIGATION OF DISEASE.—At a recent meeting of the Alumni Association of the Philadelphia College of Pharmacy, F. E. Stewart, M.D., Ph. G., read an essay entitled "The Relation of Pharmacy to Therapeutics," in which the interests of the physician and the pharmacist were both shown to be opposed by the proprietary-medicine trade; and it was claimed that the true interests of science demanded the discontinuance of the use of secret remedies by the public. Both pharmacy and therapeutics would be gainers by such a course. In conclusion, the lecturer advocated, for the advancement of science, a collective investigation of the materia medica of the world by the United States government, by founding at Washington a government laboratory provided with sufficient men, apparatus, and means for doing scientific work on drugs. Each department of the knowledge of drugs should be represented. There should be departments of botany, agriculture, history, chemistry, microscopy, toxicology, pharmacy, physiology, and therapeutics: a department of botany, to identify and properly classify medicinal plants; of agriculture, to study their cultivation; of history, to compare them with each other with regard to their relative importance as remedial agents; of chemistry, to investigate their active principles, and to learn the best methods for their extraction; of microscopy, to determine their structure, and for the purpose of identifying drugs and preventing their adulteration and substitution; of toxicology, to investigate their properties as poisons, and to ascertain their antidotes; of pharmacy, to prepare them aright; of physiology, to determine their actions on animals for the purpose of studying physiological therapeutics; and of therapeutics, to send them out for clinical test in the hands of the profession, guided by the knowledge already collected by the laboratory.

This work should include both old and new drugs. Our knowledge concerning some of the oldest drugs in the materia medica is but limited, and much of the information that exists in the text-books is trashy as far as therapeutics is concerned. It needs a thorough sifting and revision, after careful experiment is made to prove what is true, and to separate the wheat from the chaff.

When a new drug is discovered that seems to bid fair to be of value as a therapeutic agent, let it first be tested physiologically on animals, and, if it prove to possess activity, let it be submitted to chemical analysis. Then let it be prepared in the best form for administration, and sent to the hospital service of the country, and to the medical profession at large, so that its virtues may be tested clinically. That the medical profession may be

well informed with regard to the drug, so that they can make such tests in an intelligent manner, let "working bulletins" be prepared, giving, briefly, the state of existing knowledge concerning the drug after it leaves the investigation of the laboratory. Accompany the bulletin with a list of questions stating what it is desirable to ascertain about the drug, requesting answers from the profession. When sufficient information is thus obtained to justify its compilation, let it be collected and classified in the forms of science, and published for the benefit of science. Thus would be founded a scientific pharmacological literature, progress in the knowledge of drugs would be promoted, the position of both professions improved, and the cause of suffering humanity greatly benefited.

"There is at Washington an institution known as the Smithsonian Institution. Its founding is due to that great lover of science, James Smithson. Its object is the increase and diffusion of knowledge among men. This institution is devoted to scientific work. It is well provided with money, elegant buildings, a fine library, an excellent laboratory, and a corps of scientific men. The work of the United States Fish Commission, National Museum, and scientific research in other departments of science are too well known for comment here. It is suggested that there be added to this institution a laboratory of experimental pharmacology for the purpose described.

"To sum up, therefore, pharmacy and therapeutics are but branches of the science of drugs, and dependent upon the materia medica. The science of drugs is properly called pharmacology. Pharmacology is a department of the science of medicine. The pharmacist and physician are both votaries of medical science, though interested in different branches. To prepare medicine aright, pharmacy must conform to therapeutic usage, and the physician is dependent upon the pharmacist for such preparation. In the study of the materia medica both professions meet, and in favoring the progress of pharmacology their interests are mutual."

After discussing this paper, it was voted that it is the sense of the meeting that this suggestion be adopted, and the founding of such a laboratory at Washington in connection with the Smithsonian be recommended.

ST. JOHN LONG'S LINIMENT.—This old-time liniment is still in use at the Pennsylvania Hospital, in this city, for stiff and rheumatic joints, and in general for cases in which a local stimulant and rubefacient effect is desired. Mr. Jacob Hecker, Ph.G., the apothecary of the institution, uses the following formula:

R Vitelli ovi, no. viij;
Olei terebinthinæ, f̄xxiv;
Acidi acetic, f̄xxvj;
Aquæ, f̄xxiv. M.

The directions for its preparation are as follows. To the yolks, in a gallon-bottle, add a small quantity of the water, and shake briskly together; then add the turpentine in successive portions, shaking the mixture briskly after each addition; then add the acetic acid, and lastly the water, in the same manner. For private practice the liniment is greatly improved by the addition of one drachm of good oil of lemon to each pint.

MISCELLANY.

A PHILADELPHIA NEUROLOGICAL ASSOCIATION.—A preliminary meeting of physicians interested in the study of nervous diseases and psychiatry was held at the hall of the College of Physicians on Saturday evening, the 15th instant, at which Dr. Kerlin presided. It was well attended, and much interest was shown by those present. A series of resolutions was adopted, declaring the intention of those present to meet early next month for the permanent organization of a society for the study of neurological science in all its departments, consisting of physicians of Philadelphia and vicinity. Drs. Charles K. Mills, Wharton Sinkler, R. H. Chase, J. T. Eskridge, and A. P. Brubaker were appointed a committee on Permanent Organization, the society to meet at the call of the chairman of this committee, for organization.

The following were present at the meeting: Drs. C. K. Mills, Wharton Sinkler, Francis Dercum, J. T. Eskridge, James Hendrie Lloyd, Nathan A. Randolph, Edward T. Reichert, A. P. Brubaker, Lambert Ott, Max Bochrach, Lewis Brinton, William M. Angney, S. Preston Jones, D. D. Richardson, Emily P. Avery, J. N. Kerlin, Robert A. Given, R. H. Chase, Alice Bennett, and George Moorehouse.

Those present indicated their intention of co-operating in the movement, and letters of approbation were received from other neurologists and alienists who could not be present.

DEATH FROM PHOSPHORUS-POISONING.—The death of a girl, aged 2½ years, is reported from Lenzie, Scotland, and everything points to its being a case of poisoning from sucking the phosphorus off matches. Some days previously she had been playing with a box of matches, and it was observed that the phosphorus had been sucked off several of them. Symptoms of poisoning showed themselves a few days afterwards, and she died in considerable suffering, after a short illness.—*British Medical Journal*.

IODOFORM AND CALOMEL.—As this combination is often ordered by specialists as a dusting-powder, it may be of interest to know that the ingredients are, to a certain extent, incompatible. S. J. Bendiner, in a communication read before the New York College of

Pharmacy, recently, stated that iodoform and calomel are decomposed by light at an ordinary temperature, such decomposition taking place as well by exclusion of the chemical rays. Consequently, these substances rubbed together can only be safely dispensed in black glass bottles.—*Druggist and Chemist.*

DR. WILLIAM THOMSON has changed his residence from No. 1502 Locust Street to No. 1426 Walnut Street, Philadelphia.

NOTES AND QUERIES.

THOMAS STORY KIRKBRIDE, M.D.

A severe attack of pneumonia, which Dr. Kirkbride suffered last March, produced a condition of debility which finally led to his death on December 17, at the hospital to which he had devoted the best powers of his life, and which remains an enduring monument to his faithfulness and skill.

Thomas Story Kirkbride was a native of Pennsylvania; he was born near Mooresville, Bucks county, July 31, 1809. His ancestors were members of the Society of Friends, and were among the early settlers of the State. His academical education was acquired at Trenton and Burlington; his medical studies were inaugurated under the direction of Dr. N. Belleville, of Trenton, and continued at the University of Pennsylvania, where he received his degree in March, 1832. After a year's service as interne in the Friends' Asylum for the Insane at Frankford, he entered the hospital with which his whole future was to be identified, in March, 1833, as resident physician. At this time all of the departments were located at Eighth and Spruce Streets, Philadelphia. Having served a term of two years, he engaged in private practice for the next five years, during which period he also served for a time as physician to the House of Refuge, to the Institution for the Blind, to the Magdalen Asylum, and other public institutions. At this time, the managers of the Pennsylvania Hospital having secured a large piece of ground on Haverford Road, west of Forty-Second Street, in West Philadelphia, and having erected upon it a special building for the accommodation of insane persons, Dr. Kirkbride was tendered the position of superintendent, which he accepted. The new hospital was opened January 1, 1841, and the new superintendent at once entered upon the duties which ceased only with his death.

Under Dr. Kirkbride's able and attentive administration the new hospital became so popular and he became so identified with its success that for many years it was better known to the public by his name than by its proper title. In 1854 he urged upon the Board of Managers the necessity of increased accommodations, and recommended the erection of an additional building, which would permit entire separation of the sexes. His carefully-prepared plans for the new building were adopted, and the entire amount (over \$355,000) required for its erection and furnishing was obtained by private contributions. The new building, which is now known as the female department, had an equal capacity with the former one,—of two hundred and fifty patients. Since October 27, 1859, when this department was formally opened for the reception of patients, Dr. Kirkbride has continued to reside in it with his family.

The reputation of Dr. Kirkbride rests chiefly upon his ability as an executive officer, and upon his humane methods of treating cases of mental disease. Under his able direction the Insane Department of the Pennsylvania Hospital has obtained a celebrity that may justly be said to be limited only by the bounds of civilization. His contributions to literature were chiefly in connection with subjects of hospital construction and administration. In addition to his valuable series of annual reports to the Board of Managers for the last forty-one years, he published a work on "The Construction, Organization, and General Arrangement of Hospitals for the Insane," and a number of minor monographs, among which are "Rules and Regulations for Hospitals for the Insane," and "Rules for the Government of those Employed in the Care of the Insane," besides some contributions to current medical literature.

One of the originators of the Association of Medical Superintendents of American Institutions for the Insane, he served the organization for nine years as its president, thus showing the high esteem in which he was held by his colleagues. He was an honorary member of the Psychological Association of England, a Fellow of the Philadelphia College of Physicians, and he also belonged to several other medical and

scientific organizations, including the American Philosophical Society. He was a manager of the Institution for the Blind in this city from the time of its foundation.

Dr. Kirkbride was a true gentleman; modest, courteous, refined by nature, the secret of his successful career was one of patient continuance in well-doing, his genius that of accomplishment. He probably never had robust health, but, in reviewing his work, it looks titanic in comparison with his weak physical frame. The world may, or may not, know its greatest men; but it certainly requires more than usual discrimination to appreciate those elements of character which are the foundation of true greatness.

WILLIAM H. HOOPER, M.D.

Dr. William H. Hooper died, December 18, at his home in this city, from a complication of diseases. He had suffered during the yellow fever at its last visitation here, and during the last few years of his life was a sufferer from severe hepatic disorder. Born in Worcester County, Maryland, August 7, 1824, he came to Philadelphia before his twelfth year, and obtained his academical education at the University of Pennsylvania, where he received his degree of A.M. in 1845, and subsequently he was graduated in the Medical Department in March, 1848. With the exception of eighteen months' study in Paris hospitals, he devoted himself to private practice and with marked success. He was a member of the Philadelphia College of Physicians and other Societies. He received the nomination for coroner on the Democratic ticket last September, but failed of election; this disappointment probably hastened his death.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM DECEMBER 8 TO DECEMBER 22, 1883.

CAMPBELL, JOHN, LIEUTENANT-COLONEL AND SURGEON.—

Having completed the duties pertaining to the office of the Medical Director of the late Department of the South, to proceed from Newport Barracks, Kentucky, to New York City, and assume the duties of attending surgeon in that city. Paragraph 12, S. O. 284, December 12, 1883.

CLEMENTS, BENNETT A., MAJOR AND SURGEON.—Relieved from duty as attending surgeon New York City, and detailed as member of Army Medical Examining Board, now in session in New York City. Paragraph 12, S. O. 284, A. G. O., December 12, 1883.

McKEE, J. C., MAJOR AND SURGEON.—Assigned to duty as Medical Director Department of the Columbia. G. O. 31, Department of the Columbia, December 3, 1883.

SHUFELDT, ROBERT W., CAPTAIN AND ASSISTANT-SURGEON.

—Now on sick-leave, relieved from duty in the Department of the East, and assigned to temporary duty in the office of the Surgeon-General of the Army. Paragraph 12, S. O. 284, A. G. O., December 12, 1883.

WILLIAMS, JOHN W., MAJOR AND SURGEON.—Leave of absence on surgeon's certificate of disability granted in S. O. 157, November 12, 1883, Department of the Columbia, extended five months on surgeon's certificate of disability. Paragraph 6, S. O. 286, A. G. O., December 14, 1883.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY FROM DECEMBER 8 TO DECEMBER 22, 1883.

Assistant Surgeon L. W. CURTIS detached from the "Adams," and ordered to the coast-survey steamer "McArthur."

P. A. Surgeon F. C. DALE detached from the coast-survey steamer "McArthur," and ordered to the U.S. steamship "Adams," at Sitka, Alaska.

Surgeon F. M. DEARBORNE placed on the retired list from December 10.

P. A. Surgeon A. C. HEFFINGER, in addition to his duties at the Navy-Yard, ordered to attend officers at Portsmouth, New Hampshire.

P. A. Surgeon C. T. HIBBETT detached from the "Onward," and ordered home.

Surgeon J. W. ROSS detached from the U.S. steamship "Iroquois," and ordered to the U.S. steamship "Onward," at Callao, Peru.

PHILADELPHIA, JANUARY 12, 1884.

ORIGINAL LECTURES.

CLINICAL LECTURE ON URETHRAL STRICTURE.

BY FESSENDEN N. OTIS, M.D.,

Clinical Professor of Venereal Diseases in the College of Physicians and Surgeons, New York.

GENTLEMEN,—You will remember that two weeks ago to-day an operation was performed on two individuals at this clinic, for the relief of urethral stricture. In one of those cases there had been recurring cystitis for a long period, and apparently without provocation, coming on without the patient being conscious of having indulged in any excess, of having taken cold, or anything that could be discovered as an imprudence. It was suspected that there might be some cause within the bladder, and the patient was repeatedly examined, but without result. He was suspected of having stricture, but there was a difference of opinion on that point. Several surgeons believed there was no stricture, while at least one, after examination, claimed that there was more or less stricture, causing the repeated attacks of cystitis, and advised the patient to come here and have the matter settled and attended to if possible. He came on from Michigan the week before last, and was then presented to you with his history.

The circumference of the penis in this case was about three inches and five-eighths. Examination was made before you, and, with the aid of the urethrometer and bulbous sound, two strictures were demonstrated, one contracting the canal at between two and a half and three inches fully eight millimetres, and the other, at the anterior portion of the canal, of ten millimetres, commencing at the orifice and extending about a half-inch. Division of the anterior stricture was made with a straight blunt bistoury, and the deeper one with the dilating urethrotome, both up to thirty-six mm., and a No. 36 sound was passed into the bladder. The results of the operation have been in every way favorable in this case. There has been no hemorrhage, and no complication of any kind. An instrument has been introduced every two or three days since that time, and certain beneficial results

are already recognizable. Dr. Blake White, one of our clinical assistants, has had charge of the after-treatment. I have not seen the case since the day it was operated upon until this morning, and I have not had opportunity of making inquiries as to what changes have been effected. I would say, however, that in cases of recurring cystitis from stricture, and particularly from strictures of large calibre, the relief is sometimes immediate. But, again, it may be quite slow. Certainly, if this be the cause of the cystitis,—and it has been proved that cystitis may result from stricture,—relief follows the removal of the stricture, sooner or later. A case in point is that of a gentleman under my care several years since, who suffered from gleet. He was about sixty years of age, and came to me repeatedly with his gleet. I referred his trouble finally to stricture, which was found of large calibre, at three and a half inches from the orifice. The normal size of the canal was 34 or 35, and at this point there was a contraction of about three or four millimetres. I regarded this as the probable cause of his trouble, but he declined any operative measures. He was under my care a long while for recurring gleet, and at last he began to have some signs of irritation at the neck of the bladder. I then again stated to him that I thought it very important that he should have this stricture relieved, as I believed it was the cause of the gleet and of the irritation at the neck of the bladder. He declined the proposed operative measures with some warmth, and desired to be treated for his trouble in the ordinary way. He did not desire to have his urethra cut. He thought that ordinary means should be sufficient. Within a few days he came back, however, with an increase of the irritation, which finally resulted in a cystitis. He was put to bed, and, in spite of everything that could be done for him, he lay for at least a couple of months, being several times in great danger of losing his life from the acuteness of the cystitis, which extended evidently up the ureters and affected the kidneys to a greater or less extent. There was at one time some evidence of uræmic trouble. It seemed, however, that it was sympathetic, and not the consequence of pyelitis, as the subsequent history proved.

The patient, under the usual remedies

for acute cystitis, began to improve, and, from passing water every few minutes, he gradually passed it less and less frequently until he had an interval of from three to four hours, finally making a recovery. After having been apparently well for several weeks, he returned with an increased frequency of urination. Again stating to him that the probabilities were that this stricture was the cause of the return of his trouble, he became very anxious to know whether that stricture was really the cause of the suffering from which he came so near losing his life. When I replied in the affirmative, he became very indignant to think that he had not been forced to have the operation done. He said, "Doctor, you should have taken me by the throat, and held me down, and operated upon me!" All very well. But suppose I had done so, and the operation had not turned out so well? We are not accustomed to treat our patients in that way. We have to rely upon their consent; we have to reason with them, and if they are not capable of appreciating our reasoning they have to take the consequences. He said, "I want the operation immediately." I replied, "No. Here you are in the face of another cystitis, and I do not feel justified in operating upon you without a consultation with some authority, so that somebody shall help to bear the responsibility in case this cystitis should go on in spite of the operation and your trouble become worse than it was before. It then might be attributed to the operation." In this case I called in Dr. Markoe, and after a careful consideration of the difficulties of the case, although there was evident advancing cystitis, it was concluded to add a traumatism to this condition; that is, to make an incision into the urethra, which, under the circumstances, might have been considered by some surgeons well calculated to aggravate the trouble. The operation was done on the same day that the consultation was held, and, from passing his water every hour or two, immediately following the operation the intervals were increased to four or more hours. The patient had, practically, no further trouble, and within a week was about again, and from that day to this, now more than five years, he has had no more cystitis; not even any re-contraction of the stricture, as proved by a recent re-examination.

Now, that was a case in which there was immediate, positive beneficial result, and I have seen not only one such case, but several. It was for reasons deduced from cases like this that, when this patient came to us with recurring cystitis, it immediately occurred to me to examine the urethra to see if the same cause had not been the origin of the same trouble. The operation was done, and the immediate result the patient will now tell us. He says that he does not think that he had to urinate so often immediately after the operation. Since then, a day or two will pass with scarcely any irritation, and he will not have to pass water for three or four hours. On other days he has to pass water more frequently, but at no time so frequently as previous to the operation.

It would seem, therefore, that there has been some immediate beneficial effect produced. Sufficient time has not passed to enable us to pronounce upon the results so far as the cure of the cystitis is concerned. We will now show you the condition of the urethra after the operation of division." At the original examination the circumference of the penis was found to be three and five-eighths inches, which would—accepting the proportionate relation between the circumference of the penis and that of the urethra, which I have often referred to—call for an instrument of 35 or 36; and, although we were able before to pass a No. 36, I should be perfectly satisfied to pass a No. 35 to-day, as some slight swelling of mucous membrane usually remains for some weeks after the operation of dilating urethrotomy. This instrument, you will observe, passes without any effort on my part to force it down. Now, what we set about in this case was to remove the stricture. That was the immediate object of the operation. Consequently, by so far we have done exactly what we intended to do. We have relieved the stricture, as demonstrated by the passage of the instrument, thirty-five millimetres in circumference, two weeks afterwards, and without any signs of sensitiveness on the part of the patient. The removal of the strictures has been accomplished without any accident occurring since the operation. There has been no hemorrhage. Hemorrhage is one of the accidents that we look for as quite likely to follow the operation immediately.

I had not time last week to say anything

to you about the subject of hemorrhage. It is important for you to understand that, in these cases, we cut into vascular structures deliberately, and with the purpose of dividing them, and we thereby put them in a condition to bleed, and consequently we should always be prepared to arrest any resulting hemorrhage. It is a very curious fact, which will be observed by those of you who shall have much to do with these operations, that in a very considerable proportion of them there is no bleeding that can be called a hemorrhage at all; that but a few drops of blood, perhaps a few drachms, may be lost at the time of the operation, and then scarcely more than a few drops at each introduction of the sound, until entire healing takes place. Now, this is so common a fact, that in a report of nineteen cases by Dr. Tilden and Dr. Watson, surgeons to the Boston Dispensary, and published lately in the *Boston Medical and Surgical Journal*, there was not a single instance of hemorrhage. I was exceedingly sorry—as I wrote Dr. Watson, in congratulating him on the completeness of the report and the success attending the operations—that no such accident had occurred, because one not familiar with the possibilities under such circumstances might infer from a series of nineteen cases without hemorrhage that hemorrhage was not likely to occur, whereas the probabilities would be that in the first case which came to the novice he would have a profuse hemorrhage. That is the usual luck of doctors who are beginning, as a rule. They often get into trouble that men who are familiar with the operation have not seen, perhaps, for a very long time.

It has occurred to me repeatedly to be called in consultation for this trouble in just such cases. Why hemorrhage does not take place more frequently after division of urethral stricture, or, rather, why it does not always occur, is difficult to say; but there are certain cases which bleed from the time of the operation persistently for days, unless some means are taken to prevent it. Only recently I received a hurried dispatch from a surgeon in the country, who had operated upon between three and four hundred cases and had never had any trouble of account from hemorrhage,—never any that he was not able immediately to control. He wrote me that he had an important patient in

whose case he had cut in the anterior urethra, and he had bled constantly for ten days; and he wanted to know what he could do for him. The bleeding was becoming quite a serious matter, besides being a trouble and an annoyance to the man, who had reason to suppose, when he submitted to operation, that he would be able to be about his business in a few days. The doctor said that if the bleeding were anywhere where he could cut down and tie the vessels, he would not care; but here he could do nothing of the kind. He had tried all the ordinary measures, and the hemorrhage would not stop. Finally, however, the hemorrhage was controlled, and the patient made a satisfactory recovery.

We should, then, in the first place, appreciate the fact that a little gush of blood may occur at the time of the operation, which may be controlled by a towel wrapped around the penis, and there may not be any more until the patient attempts to urinate, when, perhaps, there will be another gush.

Now, in the majority of the cases, no flow of blood that amounts to much occurs; but now and then a gush takes place which is considerable—say half an ounce—and requires some means to arrest it. Then, again, erection, especially occurring at night, may bring on hemorrhage. Now, these hemorrhages may occur where you only divide the meatus. I have seen a man bleed as much as a pint from a simple division of the urethral orifice; and that, too, in a very little while. These experiences teach us that every case, whether of division of the meatus or of the deeper urethra, should be treated as though it were a case in which hemorrhage would surely occur; and then we would never be taken unawares. I take every precaution in every case, even of division of the orifice, which we then make to correspond to the size of the urethra behind it. I insist upon it that the patient shall go home and go to bed and have some one to look out for him. I take the measures which I shall show you for stopping hemorrhage immediately following the operation, and then I instruct the attendant who remains with the patient to make pressure at the end of the penis the length of the cut, until any hemorrhage that may occur shall have ceased. Now, this may seem to you, and

I know it appears so to many surgeons, to be making too much of so simple an operation. But I will give you an account of a case which occurred within the past two months. A gentleman came to me who had long suffered from a gleet, apparently the result of contraction, within half an inch of the orifice. I proposed an operation. He was very anxious that his friends at home should know nothing about it. He was not willing to have the operation done at his home in Harlem, but desired to have it done at my office, and begged very hard to be permitted to take care of himself. He said, "Now, I am not a child, or a woman, and I am not afraid of blood. I am perfectly cool about matters which trouble many people, and I do not think, even if I should have hemorrhage, that I shall fail to take care of it myself. After all you have described to me, it seems very simple indeed. All that I have to do, if I have bleeding, is to take hold of the end of my penis and press it together until it ceases." I said, "Very well. It seems to me that you are a man who can take care of himself. I have had a good many patients who have undergone the operation, taken care of themselves, and done very well." In this case, as I usually do, I took a couple of pieces of pasteboard and placed them on either side of the penis, and encircled them with several india-rubber bands. He went home very confident. He came back on the following day, and said that he had been brought into a very low place. He went home, and got along very well; went to bed as usual. He lived in an apartment-house, and in the night he got up to urinate. He took off the wrappings from his penis, and after urinating he saw that instead of passing urine he was passing blood, and he said he had a very confused sensation, and the next he knew there were about a dozen people in the room, from all quarters of the house. They had sent for two or three doctors, and his wife thought he was dying. Instead of this, he had simply observed the blood, and had fainted away with his pantaloons down. The man had probably lost altogether about two tablespoonfuls of blood. The matter excited a scandal in the house which I do not suppose has been explained up to this time. Now, I merely relate this to show you how little a matter, when neglected, may put a very respectable family under a cloud. I

never, under any circumstances, cut the orifice in my office without being thoroughly satisfied that the case is going to be well taken care of for three or four days, although no bleeding may occur at the time of the operation.

A very worthy merchant of this city had irritation at the neck of the bladder, for which I believed contraction at the orifice was responsible; and such turned out to be the case, as relief of the irritation occurred immediately after the operation. I explained to him how necessary it was that he take care regarding a possible hemorrhage. He was anxious and urgent to go down about his business, but I kept him for four days, introducing an instrument daily, and he had no hemorrhage, and he began to look at me in a very curious way and to question whether I was not making a little too much ado about the matter. He asked if I did not think that he could safely go down to his business the next day. I told him that I did not know but that he might; that he was doing very well, but that sometimes hemorrhage took place even after several days. I told him that before going to his business he might come to my office, and I would pass an instrument through the orifice. Up to that time there had not been lost half a dozen drops of blood since the operation. I passed the instrument very carefully down as he stood in my office, and, as it was withdrawn, out came a gush of blood. He bled perhaps a tablespoonful. Turning very white, he said, "Doctor, I beg your pardon. I thought you were making too much fuss about this; but I will now go home." And he went home, and stayed there for several days without urging.

Now, it may seem very unnecessary to take up so much time about so small an operation as division of the meatus, but I have had experiences which make me respect even division of the meatus, and I always insist that the patient have somebody with him during the night following the operation,—one who shall look after him, to see that he does not bleed during a temporary erection in sleep. I have never forgotten, when speaking of the possibilities of hemorrhage occurring under these circumstances, a case which I have before alluded to, in which there was a loss of a pint of blood within an hour. Dr. Markoe was once called to a case of

hemorrhage from the urethral orifice, just exactly how occurring I do not remember, in which the patient died from hemorrhage by the time he arrived. Now, such an accident is not at all likely to occur; but I tell you the worst in order that you shall be induced to take all precautions, for we often hear surgeons speaking of the operation as a trifling one, stating that immediately afterwards they simply send the patient home. I believe that, as a rule, such patients will do well; but, by reason of the exceptions, you should always be prepared for the hemorrhage which may possibly occur.

In cases of division of the orifice alone, we take a couple of pieces of pasteboard, about two inches wide, and apply them on each side of the penis, then either retain them by means of rubber bands or by means of a bandage with the end divided into four or six tails. After making three or four turns, tie, making as much pressure as may be required. Secure the tails by tying. After applying such an apparatus as this, the patient may go home, and, if it is uncomfortable, he may take it off. This is the measure adopted where hemorrhage continues to occur during urination and erection.

When the hemorrhage is deep down anywhere in the pendulous portion of the urethra, it is usually sufficient to put an ordinary bandage around the penis. This, as a rule, prevents hemorrhage; but it is always well in such cases to make a little pad and put it in the perineum, and have a stick, the end in the form of a crutch, to pass from the foot of the bed up to the perineum, that, if necessary, the patient may make pressure against the pad in the perineum, occluding the urethra at that point, and thus preventing the blood going back into the bladder. Urine drawn directly from the bladder with the catheter, and containing blood, shows that blood has gone back into the bladder; or this may be inferred if vesical tenesmus occurs. This accident is not likely to occur where the division has not been made farther back than four inches from the orifice, but it is not infrequent when the cut is at or beyond four inches. Therefore, it is desirable to have an apparatus which can always be easily extemporized, which will secure the patient against hemorrhage into the bladder. All that you will then have to do is to make

pressure at some point anterior to the cut. You can thus certainly control hemorrhage. My custom has been, when bleeding of considerable moment has occurred, to take an ordinary gum-elastic tube, or some other tube with an open end and which is well rounded at the end, so that it will not injure the urethra, pass it down beyond the cut, and retain it by means of a bandage. By this means pressure can be made so that it will be impossible for further hemorrhage to take place. The ordinary endoscopic tube answers a very good purpose, and I have used it on several occasions. I have here also some rubber tubes made for this purpose, consisting of a firm, soft, smooth rubber, which can be passed down the urethra and a bandage be applied. If the endoscopic tube is used, the obturator is removed when the patient desires to urinate. I have rarely had further trouble after using one of these tubes. If the presence of the instrument causes discomfort, it can be removed; but, as a rule, the patient will bear it long enough to arrest the hemorrhage. Should this tube not prove effectual in any given case, I introduce an ordinary catheter down below the cut, making pressure in the perineum, and then gently, with the Davidson syringe, introduce water of a temperature of 120° F., under which the mucous membrane distinctly pales, and thus immediately arrest hemorrhage. I should not hesitate to carry the temperature up to 125° F. I have a patient who has been under my care for the past two weeks, who has gradually carried the temperature of the injections for gonorrhoeal trouble up to 130° F. with perfect immunity. But I should begin with a temperature of 118° to 120° , and I should feel satisfied that this plan would arrest any case of hemorrhage that is likely to occur. Such are the measures which will relieve you of the embarrassment of having hemorrhage which you cannot otherwise arrest.

In the case of this patient, I shall keep track of him, examine his urine, and treat the cystitis just the same as if no operation had been done; for it is not necessary to give up the ordinary measures of treatment because of having divided the stricture; and I shall let you know the further progress of the case.

The other patient before us is one upon whom we operated at the same time for

persistent gleet. The gleet had continued for some time, in spite of much and varied treatment. The man had become discouraged, and he came on here from a Western city by advice of his physician to see what could be done to relieve him. I was very much interested, in reading the report of the nineteen cases reported by Drs. Tilden and Watson, of Boston, already alluded to, in the large number of cases of gleet in the list, some of several years' duration, which were cured within a month or two after the operation. We all, who see much of gleet, know that it goes on with the ordinary methods of treatment for many months, and even years in certain cases. As a rule, division of stricture results in the speedy cure of gleet. If, then, by division of stricture the cause of the gleet can be removed, such a mode of cure has the great advantage of promising permanent cure instead of temporary relief.

In the case of the second patient whose strictures were divided, an instrument No. 35, you will observe, passes very easily, and the purulent discharge has practically disappeared. Within a fortnight from the date of operation it has dwindled down to a slight amount of transparent mucus. The result, therefore, has been a very satisfactory one.

These two patients, when erections have occurred, have had slight chordee. This, following the operation, is very common, and it leads me to say that in all cases before doing the operation you should, in the first place, as far as possible reduce the inflammation that may be present. Reduce the discharge to a minimum, and, when you find that you cannot bring it down any lower, then it is time to operate. I have in several cases had to operate during an acute and profuse discharge, but the inflammation had lasted for five months acutely in one case, and the reason for the long duration of the inflammatory stage was that the urethra was full of constrictions. These strictures had to be divided before the discharge could be relieved. After the operation the patient made a very good recovery, but with marked incurvation on erection, causing temporary pain. This lasted in some degree for about a month, and then finally subsided. The greater the amount of irritation and discharge, or engorgement, or inflammation from any other cause,

sexual or otherwise, the more likely will the patient be to have chordee following the operation. I have never had a case in which it did not pass off after a time. This is one of the possible complications to be borne in mind. But these operations are not done for pleasure. They are done for an important object, and, when considering their disadvantage, or the annoyance which they cause, we must bear in mind the advantages which are expected to be gained. Patients sometimes forget the reasons which led them to submit to operations, and become impatient when cure does not follow promptly and painlessly. They should be told of possible accidents beforehand, when you are reasoning with them concerning the ultimate discomforts and dangers of their gleet, or vesical irritation, and its mode of cure. Have your patients coincide with you in the course of treatment which you propose to pursue. If the patient declines the operation, five or ten years after he may be obliged to have it done when the conditions are not quite so favorable. These patients are ever in danger of attacks of gleet, of prostatic irritation, of reflex neuralgias of the testicle and the pelvic region, of cystitis, or epididymitis. Their lives are more or less imperilled also by their influence on kidneys predisposed to, or the subject of, disease.

Any one of these complications would alone warrant a careful search for urethral stricture, even where none had been previously suspected. It should not be forgotten that such difficulties and diseases, distinctly resulting in many cases from stricture of the urethra of large calibre, are often treated for long periods by medicines the tendency of which is to impair digestion and debilitate the nervous system, or by various local applications or injections, or bougies and sounds, into the urethra,—often into the bladder,—which may, and not unfrequently does, result in grave injury to the patient when the strictures have diminished in calibre, and have caused damage to the associated organs.

The sooner, then, that a stricture has been recognized as a source of trouble and judiciously and effectually removed, the greater will be the promise of prompt and permanent relief from the difficulties which it occasions and the perils which it threatens. In such cases, the judicious and

skilful performance of dilating urethrotomy, under favorable conditions, in my judgment, affords the necessary relief with the least discomfort, the least risk, and the least loss of time.

ORIGINAL COMMUNICATIONS.

REPORT ON THE PROGRESS OF MEDICAL AND SURGICAL ELECTRICITY.

BY WILLIAM R. D. BLACKWOOD, M.D.,

Neurologist and Electrician to the Presbyterian Hospital;
Physician to St. Mary's Hospital.

THE advance made in electro-therapeutics for some two years past has not been, apparently, either rapid or extensive; nevertheless, much has been done without its appearing in our journals. This neglect is the more reprehensible because the entire subject of the practical employment of electricity and magnetism in medicine and surgery is ignored by nine-tenths of the general practitioners, and it is but imperfectly understood by the majority of those who do attempt to use this invaluable agent. As a consequence of the little to be learned outside of special works on the subject, too many physicians who do not own such books have relied on faradic currents exclusively in all cases, partly because the mechanism involved is more readily handled and cheaper to purchase, and also because the original plant required in using galvanism is not only more expensive at first, but is also more costly and difficult to maintain. In addition, the proper methods of applying it are unknown, or, what is worse, it is used hap-hazard. It is very important that in all reported cases the *precise* method of application should be accurately described.

In considering the subject of galvanism, the batteries for producing constant currents have been much improved lately. The cumbersome, dirty, and troublesome elements which for a long time were employed have been superseded by cells of a simpler type, and the first cost of these is not alone less, but their maintenance is also cheaper. The Hill gravity, the Léclanche prism, and the Law elements are each economical and readily manageable by any one; and, as they are largely used by telegraph- and telephone-companies, such parts as may be required for repairs

are readily obtainable at low rates through dealers in all large cities.

In the treatment of migraine, or sick headache, galvanism has lately been more generally employed than heretofore, and in most instances the use of purgatives is by this method rendered unnecessary. In the practice of the writer, galvanism has taken the place of the bromides, chloral, caffeine, and allied drugs in the majority of instances, particularly in obstinate or long-standing cases. The persistent insomnia accompanying typhoid and other low febrile conditions has been admirably controlled by galvanism.* In exophthalmic goitre an increasing list of successful results has been noted, and attention has also been called to the fact that only constant currents possess the power of acting on the heart-muscle, not alone in the disease named, but at any time; and the idea entertained by many that induction-currents were capable of modifying cardiac movement is shown to be fallacious when the electrodes are applied to the thorax in the usual manner (over the sternum and between the scapulæ). The writer is not inclined to accept the statement that faradic currents cannot modify cardiac action, *however* applied, because experiment has satisfied him that tumultuous palpitation is frequently calmed if the faradic current is directed through the pneumogastric from the angle of the jaw to the solar plexus, or the lower electrode may be applied over the sternum, the probable explanation being that induction-currents as ordinarily applied are more liable to traverse the superficial fascia around the thorax, instead of passing directly through from one pole to the other, as constant currents will.

Seligmüller† has reported very favorably on the use of electricity in acute articular rheumatism. The preferable method is to fasten one pole to the affected joint by means of a wet bandage, the other being applied above the articulation on any convenient point. Long-continued mild currents are recommended; and, although it is not stated which variety is to be used, the general tone of his remarks points to faradism, although, as is well known, galvanism is far better adapted for the relief of pain in any affection for which electricity is indicated. Hydrar-

† New York Medical Record, December 22, 1883.

throsis has been reported as notably benefited by prolonged applications of the constant current, after failure of ordinary methods of treatment, by several reliable authorities.

Attention has been called quite recently to the value of electricity in treating intermittent fever, all other remedies in these cases being avoided. The writer of this paper has given* a series of thirty cases thus treated successfully, and in a following article† has given an account of experiments made to determine the effect of electrical currents of differing character upon the so-called disease-germs. Although bacteria of all kinds are readily destroyed by electricity, however generated, it is not probable that the favorable results of treatment attained in paludal and like fevers is due to electricity as a germicide; but the benefit is more likely attributable to its action on the general nervous system, but particularly on the sympathetic. The reduction of enlarged spleen or malarial ague-cake is readily accomplished by electricity without the aid of quinine, iodine, mercury, or other sorbafacients.

In gynecology and obstetrics, electricity has been increasingly used, and many obscure cases of reflex nervous disorder due to ovarian congestion and neuralgia, which had obstinately resisted other treatment, have been overcome by galvanism. In all such cases it is essential that, in addition to the tonic effect of general applications, the main attention must be paid to the uterus and ovaries, the current being confined to them by suitable electrodes.

The cuts illustrate the rheophores used in uterine applications by the writer. No. 1, Fig. 1, is intended to confine the current to the uterus alone, as it enters by the straight rod, which is insulated to the tip, at which point the current leaves, and, traversing the body of the uterus, it enters the perforated ball, and by way of the insulated curved rod returns to the battery. The straight rod is movable lengthwise, to reach the fundus in long or short canals, and is also flexible, to pass flexions. The large perforated uninsulated ball is placed against the os externum after the intra-uterine rod is entered sufficiently, and the current is then established.

No. 2 is the ordinary sound insulated all except the intra-uterine two and a half inches.

FIG. 1.—Rheophores.

No. 3 is a ball rheophore for the cervix or the ovaries, used per vaginam.

No. 4 is a cup-shaped rheophore for the cervix.

No. 5 is the ordinary sponge-handle for external use.

FIG. 2.—Direct Uterine Electrization.

Fig. 2 shows direct uterine electrization by an intra-uterine sound (No. 2, Fig. 1), the other pole being divided and applied over the pubes and genito-spinal centre.

In all cases where electrical treatment is applicable, *localization* is followed by good results, which cannot be obtained by treatment applied aimlessly over the abdomen and back, as ordinarily seen.

Several cases are noted where post-

partum hemorrhage has been checked by faradization of the womb, after other

FIG. 3.

methods, including ergot, ice, vinegar, and hot water, had failed.

Abdominal dropsy has been considerably relieved, as reported by several observers, by general faradization. In one of the writer's cases this plan achieved the cure after ordinary treatment by diuretics, purgatives, and sudorifics failed. The patient was the son of a physician, and was convalescing from a severe attack of scarlatina, when nephritis supervened from a cold, and the albuminuria exceeded anything in his experience short of a fatal termination. In dropsy from hepatic disorder good results do not appear under electricity, as a rule, although torpid liver is readily stirred into action by induction currents.

The induction-balance has been rendered more perfect since its useless attempt in the case of President Garfield, and may in the future be of service. The various accumulators or secondary batteries are not as yet of any value, except for very short and expensive applications of the cautery or incandescent light.

The revival of static electricity from its long slumber, some two years ago,* has developed its value in amenorrhœa, spamenorrhœa, and many cases of dysmenor-

rhœa; and the facility with which this form of current is now producible by the improved Toepler-Holtz machines enhances very materially its importance to the neurologist as well as to the gynæcologist.

As a galactagogue, static electricity has proved serviceable† in several reported instances; and in the chest-pains of phthisis‡ it has not only relieved the suffering, but its effect on the general nutrition has been good. The distressing night-sweats in pulmonary disease have been modified in some instances, and in others abolished for a considerable length of time, by this form of electricity.

In constipation from torpor of the intestinal muscles, static electricity has proved of service, and in jaundice from congestion of the liver and obstruction of the biliary ducts strong shocks from Leyden jars have overcome the condition.

In surgery the galvano-cautery divides honors with Paquelin's thermo-cautery; but with a competent operator there can be no doubt whatever as to the greater utility of the electric wire, there being less radiated heat to possibly do damage to adjacent parts, to say nothing of the danger always attending the use of benzine or its compounds in unskilful hands in connection with flame. Accidents have happened repeatedly with the gasoline cautery which would with the galvanic cautery or electric *écraseur* have been impossible. Seiler§ advocates the galvano-cautery knife (of his own construction) for intra-nasal hypertrophies, and also finds the heated loop admirable for the removal of pediculated tumors of the naso-pharynx and larynx. In this he is supported by other recognized authorities.

Urethral stricture has been lately treated with very great success by galvanism in the hands of several surgeons.|| It has been long known that insulated bougies would pass narrowed points under both faradic and galvanic currents, without undue force, which could not be traversed by ordinary instruments of the same or frequently considerably smaller calibre. Under electrolysis, urethral stenosis is in suitable cases overcome with little difficulty, without forcible rupture, and the tendency to fe-

brile disturbance is less than with the more commonly employed methods.

Obstinate gleet has succumbed to electricity in instances where the discharge was probably due to contraction of the deeper urethra.*

In hysterical manifestations the application of powerful magnets to anæsthetic regions of the body has, it is stated, induced a return of sensibility to such parts, at the expense, however, of other localities, which in turn become insensitive, this phenomenon being grandiloquently termed "consecutive oscillations," a wobbling about of imaginary symptoms which radical measures—as, for example, the actual cautery (either galvanic or a simple hot poker)—would have undoubtedly relieved instantaneously and permanently.

A legitimate use of the magnet has been frequently made in ophthalmic surgery in the extraction of metallic foreign bodies which have penetrated the eyeball. Particles of iron and steel have in many instances been removed by means of specially-devised instruments, consisting of a permanent or electro-magnet attached to a slender rod or probe, which is usually introduced through the original wound of entrance. In all cases the *electro-magnet* is preferable, because the point of the extractor can be in this form placed against or near the body to be removed, before any attractive force is developed, and the actuating current can then with advantage be produced. In deeply-seated fragments of iron the attractive force of a permanent magnet of ordinary power, on the contrary, would be exerted at once on its reaching the cornea or conjunctiva before the better line of extraction could be secured; and instances have happened where the spicula has jumped promptly to a permanent magnet in a direct line before the operator intended it to act, and a second wound of the organ has unintentionally and unfortunately thus happened.

Electric lighting, both for out-door and in-door purposes, has received a great impetus within the past two years. It is too early to say authoritatively what bad effect, if any, this method of artificial illumination has had or will have upon the general health, and especially the vision, of persons

using it. A material difference exists between the two methods of arc and incandescent lamps, the former being principally used for out-door purposes or the lighting of large halls or rooms by a few powerful lights, and the latter for those instances requiring a standard of fifteen to twenty candle-power at each point, much the same as with gas or petroleum. The unsteadiness and blue tinge of the arc light is a disadvantage which must interfere with its general adoption, except for the purposes alluded to; but the soft, white, and perfectly steady light of the incandescent systems admirably fits them for all household use. The absence of the heat arising from gas, the fact that oxygen is not consumed by the light, the non-production of carbonic oxide or acid fumes, the safety from fire or explosion, and the absolute steadiness of a good incandescent electric lamp, such as the Swan, the Lane-Fox, the Maxim, or the Edison, must before long not only force their introduction into factories, large stores, public buildings, or other places where an isolated plant is economical (and in any case electric lighting on this system is more economical than gas, light for light), but, as in parts of New York City, large districts will ultimately be supplied from central stations as a matter not alone of economy but of convenience.

Several exceedingly ingenious arrangements for using the incandescent light in aural, laryngological, and ophthalmic medicine and surgery have been recently made. Minute lamps have been affixed to the laryngeal or rhinoscopic mirror for the illumination of the pharynx and adjacent regions; but the substitution of the incandescent light, applied either to the Toboldt stand or directly to the head-reflector, affords at once a brilliant light and one which shows the parts under inspection in their normal colors,—a matter of moment to inexperienced observers, who are not so ready to make allowance for this point as their elder *confrères*.†

Many other points in the application of electricity to medicine and surgery might be adverted to, but time and space forbid. It is not only the direct employment of electric currents of any or all forms to diagnosis or therapeutics that interests the practitioner, but the wonderful facility of

* Medical and Surgical Electricity, Beard and Rockwell, First Edition, p. 660; New York, Wm. Wood & Co., 1871. Blackwood, Philadelphia Medical Times, November 4, 1882, vol. xiii. No. 390.

† Baker, British Medical Journal, November 10, 1883.

intercommunication which enables the interne at a hospital to summon his chief, or the private patient to call his medical adviser to the bedside, without reference to distance, time, or weather, through the telephone exchange; and the untiring vigilance and unfailing accuracy with which electricity serves us in numerous affairs of business as a silent watchman, a faithful recorder, and an assistant not to be tampered with or bribed, render it simply a matter of time when its services will be required and secured in the production of absolutely truthful sphygmographic, respiration, and temperature charts in all complete hospitals.

Electricity is not the mysterious agent now that it was considered a few years ago, but there is still plenty to learn concerning it and its uses; and not the least important line of research is that which invokes its aid in the alleviation and cure of disease. As was said at the outset of this paper, careful reports should be made by those who employ it largely in practice, for the benefit and guidance of those not as yet proficient in its use, in all cases precision being observed as to the current used, method of application, and definite measurement.

246 NORTH TWENTIETH STREET.

EXPERIMENTAL USE OF CANTHARIDES AS A DIURETIC.

BY EDWARD T. BRUEN, M.D.,

Demonstrator of Clinical Medicine, University of Pennsylvania.

MARY G., æt. 18, a native of Philadelphia, was admitted into the University Hospital May 20, 1883. She had never been unusually exposed to bad weather, had never had venereal disease, nor had she used alcoholic liquors. Her family history was free from hereditary diseases. She had had the specific fevers of childhood, except scarlet fever. She had since been well and strong up to three years before above date. At that time she had an attack of pneumonia, from which she completely recovered, but soon after commenced to have painful micturition. Fourteen months prior to admission to the hospital the usual train of symptoms of chronic parenchymatous nephritis developed, with general anasarca. She passed the year with fluctuating fortunes, now better, again worse, always with much headache. When admitted to the hospital, her face was pale, waxy, and puffy. There was marked ascites, some double pleural effusion, and general

anasarca. She complained of constant frontal headache, at times drowsiness; pupils were small; nausea and vomiting constant; in a word, a uræmic attack seemed impending. There was hypertrophy of the left ventricle, with accentuation of the aortic second sound. The urine measured eighteen ounces in twenty-four hours, was albuminous, and microscopic examination revealed an abundant deposit of tube-casts, mostly granular, but some containing a few epithelial cells.

Treatment.—For a month skim-milk diet and other remedies were employed, without much benefit. The uræmic symptoms were constantly threatening. She was then given tinct. cantharides without other medicine, at first three drops t. d., then four times daily, and finally five times daily. The dose was also raised to six drops.

Within a week the urine commenced to increase, the uræmic symptoms to lessen, and the anasarca and dropsy became gradually reduced. When she left the hospital, in August, she was passing daily five pints of urine. The use of the drug was continued after the patient went to her home, but was finally discontinued about the middle of October. The diet during this period was, however, sedulously limited to milk-porridge or eggs. After October iron was employed.

The girl is now able to return to her occupation in a store, and is quite healthy in appearance. The urine is, however, still slightly albuminous, and contains some few casts.

The history of this case is, in its general features, representative of seven other cases, in each of which the diagnosis of chronic parenchymatous nephritis was made. In three of them the use of cantharides as a diuretic was negative; but in the other four signal diuretic action was produced.

In the dispensary of the Children's Hospital I have also used cantharides as a diuretic, combined with tinct. digitalis in cases of cardiac dropsy. The children's ages ranged from five to nine years.

In the wards of the Philadelphia Hospital I have also used cantharides in five cases of cardiac dropsy to fulfil the indications for the use of a diuretic. The use of the drug in these cases was never accompanied by deleterious effects, while it very constantly increased the urinary secretion, forming a valuable adjuvant with the digitalis. The maximum amount of the drug employed, in adults, in twenty-four hours was thirty drops, but usually not over eighteen drops were used. In the cases of the children smaller doses were employed.

The use of cantharides is mentioned by

William Roberts, of London, in his work on renal diseases, and by Dr. Wells, in seven cases. In Dr. Wells's cases, thirty to fifty or even sixty drops were administered per diem, with good effect in five cases. Ringer also reports well of it, but adds, "It is an uncertain remedy, which might be dangerous in inexperienced hands." Ringer, in the tenth edition of his *Hand-Book*, alludes to the high authorities who have recommended cantharides in certain forms of Bright's disease, and says that the "discrepancies respecting its effects arise, perhaps, from the differences in the dose administered by various observers."

He is convinced of its usefulness, even in acute Bright's disease, after the subsidence of the active inflammation and fever, say the fifth to the eighth day. He believes that in the state which follows the subsidence of the more acute stage "the urine continues small in quantity, contains albumen, and perhaps blood. If at this time, that is, just on the immediate subsidence of the acute inflammation, a one- to three-minim dose of tinct. cantharides is given every three hours, the blood will almost always quickly disappear, while the albumen decreases more gradually and the urine becomes more abundant. At a crisis like this it is true that a like amendment not unfrequently takes place without any treatment; but the influence of cantharides can often be put to a conclusive test. To a patient in the condition described above, passing urine containing albumen and much blood, give the drug in the way pointed out, and he will begin to improve. Now withhold the medicine, and both blood and albumen will return in the original quantity; and this effect can be repeated again and again." The majority of writers, however, upon therapeutics or upon renal diseases do not mention cantharides, or else, with Dickinson, are unfavorable to its use.

In the number of *Virchow's Archiv* issued November 5, an elaborate experimental study of the action of cantharides upon the kidney is reported by Dr. Eliaschoff:

The changes in the kidneys involve chiefly the glomerulus and the convoluted urinary tubules and the ascending branch of Henle's loop. At first there are the characteristic appearances of glomerular nephritis, whilst the urinary secretion is

diminished or almost suspended, is albuminous, and contains colorless and some red blood-corpuscles. There is a degeneration of the inner portion of the epithelium, which undergoes granular degeneration, disintegration, and desquamation. The peripheral part of the epithelium, together with the nuclei which have not escaped into the lumen of the tube, remains as a small continuous layer upon the basement-membrane. The ascending portion of Henle's loop is least affected. The collecting tubes of the medullary substance undergo simple epithelial desquamation. Fibrinous casts are not usually found; but Eliaschoff believes that this is explicable by the early deaths of the animals, since the degenerated cells must eventually have formed casts. Eliaschoff believes that the action of cantharides occurs principally after the separation of the cantharides in the glomerulus. When cantharides is given, the effect is produced in about half an hour. In animals killed at this period the lesions are found in the glomerulus. Later, after two or three hours, the uriniferous tubules are affected. The changes can be attributed to the cantharides flowing down the lumen of the tubules. This was demonstrated by the venous injections of the indigo-sulphate of soda. The experiments show that the greater the interval between the administration of the cantharides and the indigo-sulphate of soda, the less coloring-matter will be eliminated by the injured tubules. The author contrasts the difference between cantharides and chromic-acid poisoning as throwing light upon the physiological action of cantharides.

In both forms there are changes in the glomeruli and uriniferous tubules, substantially the same, but there is in chromic-acid poisoning an absolute destruction of the secreting epithelium, with abundant formation of casts, whilst with cantharides, although there is degeneration of the epithelium, a peripheral layer of nucleated epithelium remains. In chromic-acid poisoning, therefore, it is probable that the hurtful substance is eliminated by the epithelium and destroys it while passing through. In cantharides poisoning, on the other hand, the drug apparently acts upon the epithelium from within the lumen of the tubules.

It would appear from the above account of the physiological action, and from the writings of Ringer, that cantharides may

act as an alterative stimulant upon the kidneys. In my own cases the diuretic effect has been satisfactory in many instances, and in some of the cases the specific gravity of the urine has increased under its use; but I think the former effect is all that can be said for it in my experience. Cantharides undoubtedly produces positive effects upon the genito-urinary tract, as well as upon the renal organs, warning us that its therapeutic use must be guided by discretion.

The treatment of Bright's diseases by diuretics has been justly superseded by the dietetic and diaphoretic measures now in use. There remain, however, cases in which it becomes an absolute necessity to endeavor to lessen the dropsy by acting directly upon the emunctories. Purgatives are objectionable on account of their irritant effect upon the digestive tract: besides, they entail considerable loss of strength. The diuretic substances often offend the stomach, and diaphoretics may not be available.

The purpose of this communication is to record, in an *experimental* manner, the possible uses of cantharides as a diuretic, and to show that, properly used, its action is not harmful. The renal conditions upon which I have found tincture of cantharides act favorably are those of chronic catarrhal nephritis combined with some interstitial process, and associated with more or less cardiac hypertrophy. It has proved decidedly less useful in cases in which the heart was feeble. In these cases it may still be rendered effective when combined with preparations of digitalis, although digitalis given alone was inoperative. I have never attempted its use in cases which possessed any acute element. In the cases of cardiac dropsy it was always given with digitalis, and, since its effects as shown by the physiological action (Eliaschoff) occur partly through its local action upon the renal secreting cells, it is reasonable to suppose that digitalis, by increasing the efficiency of the circulation, should increase the effect of cantharides as a diuretic. Certainly its small bulk renders it a convenient and acceptable drug to patients, whether adults or children.

DR. THEOPHILUS PARVIN has been elected one of the Attending Obstetricians to the Philadelphia Hospital.

A NEW APPARATUS FOR THE ESTIMATION OF UREA IN URINE BY THE HYPOBROMITE METHOD.

BY WILLIAM H. GREENE, M.D.

THE estimation of urea by the measurement of the volume of nitrogen disengaged when urine is mixed with a solution of sodium hypochlorite was proposed almost at the same time by Le Conte* and Davy.† Knop‡ replaced the hypochlorite by hypobromite, and Huefner,§ Magnier de la Source,|| and Yvon¶ have devised special and admirable apparatus for the practice of the analysis.

The principle of the analysis is the same in all cases. A weighed or measured quantity of urine is mixed with an alkaline solution of sodium hypobromite: the urea at once decomposes into nitrogen and carbon dioxide, the latter is absorbed by the alkali, and the volume of nitrogen is measured. The quantity of urea contained in one hundred cubic centimetres of the urine is then calculated by the equation

$$x = \frac{100v(h-h')}{760 \times 354.3 \times a(1 + 0.003665t)}$$

in which v is the volume of nitrogen, h the barometric pressure in millimetres, h' the tension in millimetres of aqueous vapor at the temperature t , and a the volume of urine employed.

As suggested by Yvon, barometric and thermometric observations may be dispensed with, and the calculation greatly simplified, by making a simultaneous estimation of the nitrogen evolved from one centigramme of urea under the same circumstances. Let this last volume be m , and the volume disengaged from v cubic centimetres of urine be n ; then the number of centigrammes of urea in 100 c.c. of urine will be

$$x = \frac{100n}{mv}.$$

The different forms of apparatus that have been employed vary only as to the manner of mixing the urine with the hypobromite solution, and collecting the evolved gas. Several methods have been proposed and recommended, in which the decomposition is effected in a vessel con-

* Comptes-Rendus, xlvii. 237.

|| Bull. Soc. Chim., xxi. 290.

¶ Anal. chim. de l'Urine normale, Paris, 1875.

nected by means of a rubber tube with a graduated burette in which is measured the increased volume of gas due to the addition of the nitrogen to the air already contained. No great precision is attainable by any such apparatus, and at the same time the manipulation is no easier than with the apparatus of Huefner and that of Yvon, which yield exact results.

HUEFNER'S APPARATUS is in three pieces: the decomposition-tube is separated by a glass stop-cock into two portions. The contents of the lower and smaller division, including the hollow of the stop-cock, must be accurately determined. The upper compartment contains the hypobromite, and fitted to this by a ground joint is a hemispherical reservoir.

In the practice of the analysis the lower compartment and the hollow of the stop-cock are completely filled with the urine by the aid of a long funnel-tube. After closing the stop-cock, the upper compartment is filled with the sodium hypobromite solution diluted with its volume of water,

and the reservoir is filled to a convenient height with a cold saturated solution of common salt. After all air-bubbles have disappeared, the graduated measuring-tube, filled likewise with common-salt solution, is placed in the reservoir over a little projection on the end of the decomposition-tube. On turning the stop-cock the urine passes into the hypobromite solution, and there is a tumultuous disengagement of gas. In about fifteen minutes the decomposition is complete; the measuring-tube is then closed with the finger and transferred to a deep jar filled with water, in which the volume of gas may be accurately read.

This apparatus is expensive and somewhat troublesome, but very accurate results may be obtained.

YVON'S APPARATUS is much less complex than the preceding. It consists of a straight tube, open at both ends, and provided with a stop-cock near the upper fourth. It is graduated in both directions from the stop-cock. This apparatus requires the use of a deep mercury-trough, into which the ureometer is plunged until the longer division is filled. The stop-cock is then closed, and one or more cubic centimetres of urine measured into the upper compart-

ment and allowed to flow into the lower by raising the tube and opening the stop-cock;

several cubic centimetres of sodium-hydrate solution are introduced in the same manner, for the purpose of rinsing all of the urine into the lower division. The upper compartment is then completely filled with hypobromite solution, which is rapidly passed into the urine by raising the tube and turning the stop-cock. The gas collects above the liquid on the mercury, and its volume is measured after bringing the mercury to the same level in the ureometer and the trough. Special care is necessary that no air-bubbles be allowed to enter while introducing the hypobromite solution: any that may enter before that time can be driven out by suitably depressing the tube in the trough, while the stop-cock is open.

The manipulation and measuring with this apparatus are more rapid than with Huefner's, but require still greater precision. The results are exact.

A NEW UREOMETER. In order to simplify the apparatus and the necessary manipulations, I have devised the form shown in the figure on the opposite page. It consists of a small glass flask and measuring-tube in one piece. The flask is on a rather heavy base, to afford necessary stability.

The apparatus is completely filled with the hypobromite solution, and placed on a plate destined to receive the liquid which overflows during the analysis. By the aid of a pipette, of which the end is so bent that it may pass to the centre of the flask, a measured quantity of urine—one, two, or the desired number of cubic centimetres—is introduced, and the decomposition takes place as the liquids mix. The opening of the pipette must be so small that only three or four cubic centimetres run out per minute.

When the desired quantity of urine has been decomposed, a rather wide funnel-tube is adapted to the opening in the flask, and filled with hypobromite solution until the liquid is at the same level in the funnel-tube and the measuring-tube. The volume of gas is then read, and the necessary cal-

culatation made; or an aqueous solution of one centigramme of urea may be introduced, and the increase in the volume of nitrogen may be compared with the volume yielded by the urine.

This apparatus will be comparatively inexpensive, and, with proper care that no urine is allowed to flow from the pipette until the end of the latter is well in the flask, the results are as exact as can be desired for all

excepting the most precise physiological researches. The only objection is the rather large quantity of hypobromite solution required; but, as this is very cheap, the quantity used is of little consequence.

3225 SANSOM STREET.

NOTES OF HOSPITAL PRACTICE.

PHILADELPHIA HOSPITAL.

SERVICE OF WILLIAM PEPPER, M.D., LL.D.,
ONE OF THE PHYSICIANS TO THE HOSPITAL,
AND PROFESSOR OF CLINICAL MEDICINE IN
THE UNIVERSITY OF PENNSYLVANIA.

Reported by WILLIAM H. MORRISON, M.D.

ABCESS IN THE RENAL REGION.

GENTLEMEN,—This Italian was admitted to the hospital some time ago with a swelling in the left lumbar region. There was discoloration, heat, swelling, and tenderness. It was entirely clear that it was an abscess. The aspirator was employed, and thirty-two ounces of laudable pus withdrawn. The pain and temperature were greatly diminished, but the abscess gradually refilled, and two weeks after the first tapping the aspirator was again employed, and eight ounces of pus removed. Since that time the general health has steadily improved, and the abscess has refilled to a slight degree only.

What we were particularly concerned about was not merely as to the diagnosis of abscess, for that was a very simple affair, but it was as to the character and source of the abscess. By means of an in-

terpreter, we obtained the statement that ten years ago this man had precisely the same kind of a swelling in the same place, following a strain, that it went on to supuration, that it was lanced, the pus was evacuated, and the abscess closed, and that from that time until the present his health had continued good, when, without any adequate cause, a second abscess formed in the same region. The man is a wretched, broken-down specimen, as most of the Italians who come to the hospital are. They have been exposed to every cause of depraved health, and when they break down they come to us in a most miserable condition. We have been unable to obtain any other information as to the man's past history, and I am unable to say whether or not he has had syphilis.

In looking at this abscess, the thoughts which occurred to me were—(1) was it the result of disease of the bodies of the vertebræ? (2) was it connected in any way with the left kidney? or (3) was it a simple phlegmon, resulting from some injury in a man who was in a wretchedly depraved state of general health?

Observation showed that there was no curvature of the spine, no prominence of the spinal processes, and no special pain along the region of the spinal column. The history of an abscess occurring ten years ago and terminating in recovery was opposed to the idea that this was connected with serious organic disease of the bone, since in the adult a carious abscess of this character is, as a rule, very intractable, and is apt to continue running, until the patient is worn out by the disease. There seems to have been no difficulty about the cure of the first abscess, which, after being opened, readily healed.

The position of this abscess would suggest the possibility of its connection with the kidney. As we study the renal region more carefully, we find that suppurative inflammation of the kidney and of the connective tissue surrounding the organ is far more frequent than was formerly supposed. Perinephritis and perinephritic abscess are conditions far from rare. I have seen abscesses in the renal region which did not point in the back at all, but burrowed down along the spinal column, and their connection with the kidney-region was with great difficulty recognized. It was only by very careful percussion of the two renal regions, and a critical study of

the subjective symptoms of the patient and the evidences of pressure and irritation in the line of the ureter, that their true nature was recognized. In other cases, the collection of pus pointed in the lumbar region, outside of the line of the erector spinæ muscles. I have seen this in connection with suppurative pyelitis—that is, inflammation of the pelvis of the kidney—resulting from the presence of a calculus, and going on to suppuration, ulceration of the pelvis, perforation and the formation of an abscess around the kidney, communicating with the cavity of the pelvis of the kidney. I have even extracted calculi in the lumbar region outside of this line, and have seen this followed by healing of the fistula. In scrofulous children, in whom perinephritic abscess is more common than it is in adults, I have seen the abscess open in this situation, and the discharge continue until the abscess has healed or the patient has been worn out by the disease. I have had operations performed on the renal region, and pus evacuated which has evidently come from the kidney. In this case the abscess was very superficial, and the line of demarcation was quite definite. There was no pain on deep pressure in the left hypochondriac region. There were no symptoms of disorder of the urine. There was a history of an abscess in the past, which had terminated in recovery. Taking these points into consideration, we concluded that this was a curious instance of a recurring abscess in the subcutaneous connective tissue, but not connected with any serious deep-seated trouble.

The result of the case has shown the correctness of the diagnosis. There is now only a little fulness. There is some pus in the abscess; but the amount is small. If it should refill, a small opening will be made, and the abscess dressed antiseptically.

MULTILOCULAR PLEURISY.

This patient was before you about three weeks ago. He is an Italian, a laborer, and was admitted July 10. There is no known hereditary tendency to phthisis. He had had a slight cough for some time, but was otherwise well until a week before admission, when, after exposure, he was taken with a violent chill, followed by fever. The temperature on admission was 103.4° . There was likewise severe pain in the right side, and the signs of a pleural effusion were de-

tected. He was tapped three times, but only small quantities of fluid were obtained. The first tapping removed three and a half ounces, and was followed by temporary improvement, the temperature falling to normal. In a week the former symptoms returned, with rise in temperature, and he was again tapped, and four ounces of fluid were drawn off. Improvement again occurred for about a week, when the former symptoms returned, and tapping was again resorted to, but this time no fluid was obtained. When this man was before you on the last occasion, I took the liberty of discussing with you, in the absence of my colleague, the propriety of these early and small tapplings. There is a good deal to be said on both sides of the question.

Since you last saw him there has been a gradual improvement, until last week, when the temperature rose to 102° for a day or so. It has again fallen to the normal. The urine is fair in amount, acid in reaction, with a specific gravity of 1015, and contains a small amount of albumen, but no tube-casts. The treatment has consisted of iron, quinine, iodide of potassium, and flying blisters over the affected side.

When you last saw him, he looked wretched, anæmic, with an anxious expression of countenance; he had hectic fever, night-sweats, fever during the day, harassing cough, and very copious mucopurulent expectoration, which was so free that it almost filled a pint cup from early morning until ten o'clock. On examining the chest, I pointed out to you that there was over the posterior part of the right side flatness on percussion from the spine of the scapula down to the base of the chest, and from the line of the vertebræ around to the nipple-line in front, gradually sloping downward to one inch above the upper margin of the liver. Above this, in front, the chest was resonant. Over the upper part of the right chest in front, where there was good resonance on percussion, I found, on auscultation, numerous snoring and mucous râles. From the history we learn that this man, without any hereditary tendency to phthisis, had presented a cough for a certain length of time before the pleurisy developed; that the tapplings which were performed had resulted in very small discharges of fluid; and that, although the last tapping

did not withdraw any liquid, the symptoms of chest-irritation continued, attended with an irregular type of fever, with continued loss of flesh and copious expectoration, so that we were forced to consider the question whether this pleurisy was an idiopathic and original affection occurring in a comparatively healthy man, or whether this man had incipient phthisis with intercurrent pleurisy, and whether the symptoms which were present were dependent upon continued pleural irritation or upon organic trouble in the lung. You will at once see how difficult it was at that stage of the disease to decide these questions. We came to the conclusion that, on the whole, the burden of evidence was favorable to the patient. The pleurisy was of that unusual form which is termed multilocular, or cystic, in which there is a great deal of fibrin, with comparatively little serum, the fibrin being so arranged in bands of false membrane as to break the pleural cavity into a number of smaller spaces, and the serum distributed through these spaces, so that although the symptoms indicated a considerable effusion, yet the punctures which were made only opened one of these small spaces and removed but a few ounces of fluid.

In this form of pleurisy the course of the case is always slow. It takes a long time for the plastic exudation to undergo organization, and while this process is in progress there will be more or less constitutional irritation and fever of an irregular hectic type. The character of the pleurisy justified us in hoping that the constitutional symptoms might prove to be largely due to the pleural inflammation. Again, although there were these râles at the apex of the right lung, yet there was no dullness on percussion, no evidence of consolidation, no increased fremitus, and no prolongation or blowing character of the expiration: so that it was possible that this was merely a local bronchitis.

The man was put to bed; blisters were employed over the affected side; he was given cod-liver oil, with nourishing food, iodide of potassium, and a moderate amount of stimulant. The albumen soon disappeared from the urine, and from that time the man has steadily improved.

There are still some coarse râles at the upper part of the right lung in front, but less numerous than they were. There is no dulness. The pulse is still weak. We

shall place over the right apex a blister two inches square, continue the same treatment, and allow him to be out of bed for five or six hours during the middle of the day.

PHTHISIS OF MODERATE SEVERITY COMPLICATED WITH PLEURAL EFFUSION—ASPIRATION.

This man is 33 years old, and has been in the hospital nine months. He was at first under the care of Dr. Edward T. Bruen, who gives us the following account of the man while under his charge: "This patient was admitted in February last, with very few physical signs of any process in the lung, but at the same time he had a severe cough. After being in the wards for a week, he had a hemorrhage of several ounces from the lung. He then had repeated hemorrhages from week to week, which were very difficult to control. The physical signs were insignificant, and for two or three months it was difficult to demonstrate the presence of phthisis. As spring came on, the cough subsided, and at that time the signs of consolidation at the right apex presented themselves, but the signs of a cavity have never been detected." About two weeks ago he noticed a splashing sound on the left side. This was attended with a violent fit of shortness of breath. There has, then, been a history of phthisis, followed by some complication.

This is the first time that I have seen the patient, and I shall examine him before you. As he is lying on his back, the resonance on the left side in front is almost tympanitic in character. On the right side it is normal down to the liver. When the patient sits up, the resonance posteriorly on the left side is good. On looking at the right side there is at once an appearance of distention of the chest, and on percussion flatness extends from the liver up to the line of the angle of the scapula. Placing my fingers on the chest and percussing, I feel a very distinct fluctuation. I have never before seen a case in which this sign was so marked. Now when the man is sitting up there is dullness in front on the right side, where before there was resonance. When the patient lies down, the resonance returns.

We have in this case phthisis of moderate severity, complicated with a large pleural effusion of the right side. This pleural effusion is so great and the muscular tissues are so weak that the diaphragm has been pushed down and the respiratory

muscles of the right chest paralyzed. This causes intense dyspnoea, and raises a very important question,—that is, whether or not in a case of pleurisy complicating phthisis the liquid shall be withdrawn by aspiration. Internal treatment and local applications rarely remove a large effusion in such cases. It is nearly always chronic and rebellious to treatment. Shall you, therefore, operate? This question cannot be answered in the same way in every case. You must be governed by the amount of disturbance which the effusion causes, by your knowledge of the form and extent of the lung-disease, by your judgment as to how much of the symptoms are dependent on the organic lung-disease and how much upon the pleurisy, and by the question whether the phthisis was rapidly progressing or comparatively stationary at the time the pleurisy developed. If the patient has been suffering greatly from phthisis, the disease making rapid progress, and pleurisy occurs, but the distress not being much increased by it, I should be in favor of not operating; but in such a case as the present one, where the physical signs are not marked and the course of the disease is not rapid, and a pleurisy with large effusion occurs, producing great distress, I am in favor of operating. I am in favor of it, no matter what the character of the effusion; but as to the mode of operating I should be governed by the character of the fluid. I shall pass a hypodermic needle into this chest, in order to determine the nature of the effusion. If it be pus, I shall simply evacuate it to-day, and see how rapidly the pleural cavity refills. If it be serum, I shall simply withdraw the fluid with the aspirator. The fluid which I have removed consists of serum containing a large amount of flaky material.

I shall now introduce the aspirating needle; but, as you see, only a little fluid escapes. This is due to the clogging of the tube with this flaky matter. This will break down into pus. It will be necessary on a future occasion to make a permanent opening. I shall withdraw the needle and insert it at a higher point, so as to get above these flakes, which have settled to the base of the chest. The liquid flows more freely now, and we shall be able to withdraw sufficient fluid to give a considerable temporary relief. As the hour has expired, I shall continue the as-

piration after the patient has been taken to the ward, and report to you the quantity removed.

TRANSLATIONS.

THE VIRUS OF GLANDERS.—M. Bouley read a report on the "Microbe of Glanders" before the Academy, in which he reviewed the evidence in favor of a particulate infection, and declared that experiment had demonstrated that this existed in the form of a bacillus, first recognized in the discharges by Christot and Kiener in 1868, and subsequently demonstrated by cultivation experiments and inoculations made by M. Bouchard in conjunction with MM. Capitan and Charvin. In discussing this communication, M. Colin declared himself not convinced by the proofs yet adduced in favor of a specific bacillus. He declared that the virus of glanders is very persistent, and that the discharges contained many other things besides microbes, which might convey the infection, such as organic detritus, lymph-globules, micrococci, etc. He believed that the only legitimate conclusion that could be drawn from the experiments is that culture-liquids are able to transmit the poison of glanders, but he saw no proof of a special microbe. He insisted that the culture-experiments should be increased to hundreds, in order to eliminate other possible sources of contagion. He had examined the blood of persons dying of glanders, without detecting the bacillus. —*Revue de Thérapeut. Méd.-Chir.*, November 15.

THE SUPRA-PUBIC OPERATION FOR LITHOTOMY.—In a discussion upon the high operation for the removal of stone from the bladder, at the Société de Chirurgie, while considering the report of a successful case by M. Desprès, M. Perier, from an experience based upon five operations, formulated the various steps for the operation, as follows:

1. Introduction of the tunnelled sound into the bladder, and discharge of the urine.
2. Application of an elastic ligature around the penis.
3. Introduction of the rubber balloon into the rectum.

4. Distention of the bladder by warm borated water.

5. Distention of the rectal balloon.

6. Free incision of the skin and subjacent tissue down to the vesical wall.

7. Opening of the bladder, keeping the incision gaping.

8. Extraction of the stone.

9. Depletion of the balloon, and withdrawal of the sound.

10. Examination of the vesical wall, and washing out the bladder.

11. Insertion of drainage-tubes.

12. Suturing the wound above the drainage-tubes, and dressing.

M. Perier attaches great importance to drainage, and to antiseptic washes of the bladder and the wound. He uses two tubes, side by side, through which the injections are made and the discharges and urine escape.—*Revue de Thérapeut.*, No. 22.

SUBCUTANEOUS RHEUMATIC NODOSITIES.—In a recent communication made to the Société Médicale des Hôpitaux, published in *Le Progrès Médical* (Nos. 47 and 48), M. E. Troisier calls attention to a rare and curious rheumatic manifestation,—subcutaneous nodosities which show themselves near the affected joints and along the tendons during an attack of articular rheumatism, or during convalescence, but which afterwards gradually disappear. Although Jaccoud has awarded to Froriep the credit of the first mention of these lesions, it is believed that the honor of first pointedly directing attention to them is due to Jaccoud himself, who described them under the title of *induration rhumatismale* in his classical work "*Traité de Pathologie Externe*," in which the clinical features are well delineated. These peculiar appearances are not of much significance, as the majority of them disappear in a few days; but their existence has been noticed by a number of observers.

EXPLANATION OF TOXIC EFFECTS OF IODOFORM.—In a contribution to the *Centralblatt für Chirurgie* (No. 48), Dr. G. Bouma, of Leyden, calls attention to the importance of examining all iodoform that is used for surgical purposes. Much of the drug found in the stores contains impurities, and from careful observation he is satisfied that the cases of iodoform-intoxication which have been reported from some clinics have been really due to

the adulteration of the drug. In the clinic to which he is attached in Leyden, all the iodoform used is tested, and only pure iodoform is used. One specimen, which contained eight per cent. of impurities, after having been rejected, was sold in another city, and the result was noticed that serious toxic symptoms appeared in one-half of the major operations, whereas in Prof. van Iterson's clinic at Leyden, out of over three hundred cases in which pure iodoform was employed, only two presented symptoms of delirium, etc., and one with fatal results. Both of these were resections of the superior maxilla, in which tampons of iodoform-gauze had been used. Dr. Bouma is of the opinion that if iodoform be kept for a length of time exposed to light and air it may acquire poisonous properties.

URETHRO-RECTAL FISTULE — DEATH FROM URÆMIA.—Under the care of M. Desprès, at La Charité, was a case of a young man, 29 years of age, who had urethral stricture, and also a urethro-rectal fistule, probably due to a false passage caused by the injudicious use of instruments. The patient was much prostrated, and had a subnormal temperature. A very small quantity of urine was discharged by the urethra, but he had a troublesome diarrhoea, urine being discharged into the rectum. He died of chronic uræmia, and, in addition to the above-mentioned lesions, at the autopsy there were found chronic cystitis with ulceration, and contracted kidneys.

HYOSCIN IN NIGHT-SWEATING OF PHTHISIS.—Fraentzel found in twenty-nine cases of profuse sweating in phthisis, after failure of atropia, that hyoscin hydriodide in doses of $\frac{1}{120}$ to $\frac{1}{64}$ of a grain (or .0005 to .001) reduced the sweating decidedly in ten, stopped it completely in five, and in the remainder had no special effect.—*Charité Annalen*, No. VIII., and *Centralblatt für Medicinischen Wissenschaften*.

THE TANNATE OF CANNABIN AS AN HYPNOTIC.—The use of the tannate of cannabin is reported in Germany as a soporific agent. Its high price, at present, prevents its common employment instead of the extract, to which it is preferable, as it is claimed to be free from *tétano-cannabine*, a toxic convulsive principle contained in the plant.—*Revue de Thérapeutique*, December 1.

EDITORIAL.

INCISION AND DRAINAGE IN PURULENT PERICARDITIS.

WITH regard to operative surgical interference in pyopericardium, most authorities agree in considering it a delicate and hazardous operation, to be undertaken as a last resort, and only by means of the aspirator or a fine trocar and canula.

This treatment by the use of an exploring trocar was recommended by Bamberger and Friedreich, with the subsequent injection of chlorine-water or iodine, or irrigation by detergent antiseptic solutions, and is referred to also by Fothergill, who regarded it as a forlorn hope, but thought it capable of yielding relief. The practice approved by F. T. Roberts is that of removal of the purulent collection by the aspirator; but he gives this recommendation with the warning that it should not be rashly practised. Bristowe, who approves of surgical interference in pericardial supuration, gives the details of the operation: the most eligible spot for puncture he considers to be one towards the inner extremity of the fourth or fifth interspace close to the sternum, and suggests that the tissues be divided with the scalpel, one by one, until the parietal layer of the pericardium is reached, and then to puncture carefully with a fine trocar and canula; believing it advisable also to wash out the cavity, he uses a weak solution of chlorinated soda or of potassium permanganate. The preliminary use of a fine aspirating* needle for diagnostic purposes is suggested.

Dr. Austin Flint, Sr., says that in suppurative pericarditis aspiration is always indicated, but he also states that if after repeated aspirations pus continues to reaccumulate,

it is very evident that a permanent opening into the pericardial cavity, with injections, affords the only hope of effecting a cure.

Dr. Samuel West, at a recent session of the Pathological Society of London, reported a case of purulent pericarditis treated by free incision, in a boy fourteen years of age: twenty-four ounces of pus were evacuated (*Medical Times and Gazette*, December 8, 1883). This makes the third case in which pericardium has been laid freely open for purulent pericarditis. Prof. Rosenstein reported the first case, of a boy whose pericardium had been opened and drained after it had been twice tapped, who recovered, in spite of a secondary attack of left-sided pleuritis. The second case had been under the care of Dr. Samuel West also; it was an idiopathic purulent pericarditis, in which the same treatment was followed by complete recovery. In the third case death occurred from other causes: the post-mortem showed a large abscess of the thigh; but the cavity of the pericardium had been nearly obliterated in the short space of two weeks. He expressed the opinion, in presenting this specimen for examination, that opening the pericardium is not a more hazardous proceeding than opening the pleura or the peritoneal cavity, if done with the same precautions.

BOTH BANE AND ANTIDOTE.

WITHIN a few days the coroner of Philadelphia has been called upon, in the course of his duties, to investigate the death of a man who, after drinking a quart of whiskey on a wager, died in consequence in the course of a few hours with acute alcohol-poisoning. This case is not cited for its rarity, because similar cases are already on record illustrating the toxic powers of alcohol, but it is mentioned in order to point out a possible danger in the treatment of a patient who has been bitten by a venomous reptile. Dr. H. H. Hulke,

in a recent communication to the *St. Louis Courier of Medicine*, urges the trial of quinine as a substitute for at least a part of the whiskey usually given to cases of snake-bite, and expresses the opinion that there can be little doubt that more persons are killed by the enormous amount of whiskey they drink, when bitten by a snake, than from the effects of the bite itself. A general recognition of alcohol as a toxic agent, capable by its own effects of destroying life when introduced into the system in immoderate amounts, will greatly assist the community in appreciating the fact that, in smaller amounts than those capable of promptly destroying life, it may, and generally does, exert injurious effects upon the human frame. If the false sentiment which accompanies the use of this agent could be corrected, the consumption of intoxicating alcoholic drinks would be enormously reduced.

HYDROPHOBIA AND THE CRITICS.

TWO articles relating to hydrophobia, or, more correctly, rabies canina, appear in our columns in this issue,—one containing Criticisms on the Specific Theory of Hydrophobia, the other a criticism upon this paper by a valued correspondent, who prefers to be impersonal, so that his arguments may stand for themselves and be taken at their worth. Both are able communications, and will be read with interest. We therefore regret that want of space compelled us to omit a part of the original paper, consisting principally, however, of quotations from authorities. An analysis of Dr. Dulles's paper shows evidences of great industry and patience in reviewing the literature of the disease. In the first place, he has collected a number of curious mistakes in diagnosis, and of erroneous observations, both ancient and modern, concerning the pathology of hydrophobia; and, secondly, he reports that neither his individual studies nor those of

other modern pathologists have succeeded in establishing any characteristic morbid anatomy belonging to rabies. The changes found in the brain and medulla had no pathological characters whatever, such as could be recognized as the lesions of the disease. Upon facts and observations such as these, gathered during two years' study of the subject, and given in his essay, the lecturer bases the remarkable opinion that "hydrophobia is not a specific, inoculable disease derived from the bite of a similarly affected animal." Unless the author attaches some peculiar meaning to the term "special," it would seem that his views cannot be harmonized with what is known clinically of rabies: they certainly are not the natural sequence of anything contained in his communication.

Our correspondent, in criticising this view, simply reaffirms what are considered as well-established facts with regard to the pathology of hydrophobia, and expresses some truths with regard to medical logic which can scarcely be too often repeated. We think that we can accept the statement that nothing characteristic has been observed regarding the pathology of hydrophobia; but we should hesitate before adopting the view that therefore such a specific disease does not exist. How long had typhoid fever existed before its characteristic lesions were recognized by Petit and by Louis? Was there no albuminuria before Bright discovered its dependence upon renal disease?

NOTES FROM SPECIAL CORRESPONDENTS.

COLUMBUS, OHIO.

EDITOR PHILADELPHIA MEDICAL TIMES:

THE Central Ohio Medical Society held its regular meeting in December. Dr. J. N. Beach presented a stomach somewhat dilated and with a large cancerous (?) deposit at the pyloric end. The walls at this point were over an inch in thickness, but the microscope had not been invoked to decide

between carcinoma and fibroid thickening. The history of the case was its noteworthy feature. Attention had first been drawn to the abdomen by the occurrence of ascites. After the withdrawal of a large amount of fluid, the tumor was discovered. Nevertheless, during the whole course of the disease, until death occurred from progressive emaciation, the patient had neither pain, vomiting, nor hemorrhage. The occurrence of disease without classical symptoms was further illustrated by the report of a case by Dr. H. G. Landis. A multipara was suddenly attacked by vomiting and diarrhoea, the latter soon ceasing spontaneously. She had menstruated regularly up to date, and at the time when seized was having a slight show at the proper time. She had no pain, not even tenderness on pressure, no interference with micturition, and yet examination a few days later revealed a gravid retroverted womb incarcerated in the pelvis and replaced with difficulty. Pregnancy had advanced to three months. The vomiting ceased after the liberation of the womb. The Stagyrite has declared that it is a part of probability that many improbable things will happen. This was illustrated by a case reported by Dr. T. W. Jones. A ten-year old child ate freely of raw oysters. During the following week symptoms of indigestion, with fever, were present, and the mother administered sundry vermifuges without effect. Dr. Jones, being called in ten days after the molluscous repast, gave calomel and rhubarb, but without present effect. Five days later, making *fifteen* days in all, he succeeded in bringing away a large stool, in which were at least twenty raw oysters, having an odor contracted from their recent habitation, but otherwise as good as new. The account was received with marks of incredulity, as evinced by a cross-fire of questioning, well borne by the venerable reporter, and further investigation was requested. After the meeting, Dr. J. F. Baldwin accompanied the doctor to the scene of action, and failed to find anything to disprove this remarkable fact. Dr. E. B. Pratt narrated the case of a bibulous shoemaker who during an attack of delirium tremens vomited many raw oysters which had been swallowed one week before. Those who have been relying upon the self-digestibility of raw oysters will now have to pause in their mad career long enough to bite into the animal's interior. At the afternoon session Dr. Warner, a candidate for membership, read a paper upon pleurisy, which had the desired effect. Dr. Kinsman illustrated one of Dr. Da Costa's sayings by reading a paper upon consumption, which was duly discussed. The scientific work being over, resolutions were read favoring the establishment of a State Board of Examiners, who shall have exclusive power to confer the right to practise medicine in the State, and who shall make a more thorough course of study obligatory. The

discussion was opened by Dr. H. J. Sharp. He spoke at length of the low estate of the profession, comparing it with that of Europe, and claiming that the legislation contemplated in the resolutions would give us a higher order of ability in the profession. The discussion continued in the same vein until Dr. Starling Loving called attention to a few points, especially with reference to medical colleges. He averred that the fault was less with the colleges than with the profession at large, who for a paltry fee will take any one into their offices and then send him to a college to be made into a physician. If no physician would admit into his office a student who has not a liberal education, the colleges would be supplied with proper material. Further discussion was postponed until the January meeting.

COLON.

CORRESPONDENCE.

A CRITICISM ON A PAPER ENTITLED "CRITICISMS ON THE SPECIFIC THEORY OF HYDROPHOBIA."

MR. EDITOR,—Argument will scarcely fail among men as long as there are doctrines to be accepted or attacked, but it seems scarcely worth while to spend much time in proving the existence of a disease that has been known so many years and presents such distinctive clinical features as hydrophobia, merely because some one denies its existence.

We are reminded that a little book, published some seventy years ago, was the cause of much amusement from the mistakes of others respecting its nature and object. At the present day it is looked upon and valued as a literary *jeu d'esprit*. The book referred to is Whately's "Historic Doubts relative to Napoleon Bonaparte," in which, arguing exactly as Hume has done in his Essay on Miracles, the author proves that the existence of Napoleon Bonaparte is, to say the least, quite doubtful.

When anything we are asked to believe is "passing strange," we rightly demand that the witnesses in the case shall possess the following most important qualifications: first, they must have the means of gaining correct information; secondly, they must have no interest in concealing truth or propagating falsehood; and, thirdly, they must agree in their testimony.

Those on whose testimony the existence and actions of Bonaparte—the most extraordinary figure in modern history—are generally believed, fail in all these essential points: we have no assurance that they had access to correct information, they had an apparent interest in propagating falsehoods, and they

palpably contradict each other on most important points.

Very many men readily believe, and on slight evidence, any story that pleases their imagination by its admirable and marvellous character. This hasty credulity is unworthy, however, of a philosophical mind, and in proportion to the strangeness of the account should we suspend our judgment and yield to none but the most decisive and unimpeachable proofs.

Some years ago, four medical men of large experience were dining in this country with Mr. Spencer Wells, when one of them was offered a peach. He declined it, and gave as his reason for so doing that he was afraid to eat one, lest it should bring on a paroxysm of ague. Mr. Wells was emphatic in his disbelief of there being any danger to be apprehended; but the three other medical men said they knew by experience that there was. The peach was eaten, and the paroxysm followed. Mr. Wells said afterwards, when referring to this consequence of peach-eating, that he never had had lockjaw to occur after his operations except in three cases, and their history was as follows. Operating for ovariectomy, he found he had no director. Mr. Henry Smith opened his pocket-case and gave him one. That patient died of lockjaw, and the next two died of lockjaw; and Mr. Wells added that Henry Smith was then Fergusson's assistant, that Fergusson had used that director, and Fergusson then had lockjaw in his practice. To the inquiry as to whether he believed that lockjaw could be carried and communicated from one patient to another, Mr. Wells answered only *that some things were very hard to explain.*

Now, just as the peach was eaten with misgiving, so we are sure that Mr. Wells, if he used the instrument at all after what he had witnessed, would do it with great reluctance, although he might not *believe* that lockjaw is carried on an instrument, and could give no satisfactory explanation of it if he did.

Now, it is worth bearing in mind that a thing may be true without our having any satisfactory explanation of it; and, on the other hand, an explanation of a thing may long be accepted as entirely satisfactory and yet not be true at all. When the system of Copernicus was first announced, it was declared that the earth could not be turning round on its axis; for in that case a stone let fall from the top of an eminence would come in contact with the ground at a distance to the west, *in the same way as a stone dropped from the top of a mast in a rapidly-sailing ship falls on the deck near to the stern.* An answer that was satisfactory for one hundred years was this: A stone, being a part of the earth, obeys the same laws and moves with it; it is not a part of the ship, and consequently its motion is independent. When the experiment was tried, a hundred years

after this explanation was accepted, the stone dropped from the mast-head fell at the foot.

An accepted explanation does not declare the truth of an assertion. Moreover, something may be true, and yet the explanation be incorrect,—be, indeed, most plainly absurd. The accounts given in ancient writers of earthquakes and volcanic eruptions can be admitted to be true, notwithstanding their being attributed to the violent efforts of imprisoned giants to effect their escape.

From the most ancient times certain diseases have been held to be *contagious*,—that is, to be communicable, preserving special characters, from a diseased person to a healthy one. As far back as the books of Moses, indeed, we see evidence of this. A satisfactory explanation of the cause of the contagiousness was not given until the time of Fracastor, who attributed it to a specific virus; and down to the present day it is universally admitted that there does exist in certain diseases a peculiar morbid product, called *virus*, which possesses the faculty of contagion, and the smallest quantity of which, under certain circumstances, is able to develop the same disease. Syphilis, smallpox, vaccine disease, have a virulent liquid, the existence of which no one can doubt at the present day. In rabies also there is one, how prepared in the salivary glands we know not. In scarlatina, measles, diphtheria, and cholera there is also a something by which the disease may be communicated; though what this is, whether bacillar or not, is not yet well determined. Certain atmospheric and other conditions have a very great influence upon the contagiousness of these diseases,—far more, certainly, than on those first mentioned. For all disease-germs are not alike, any more than are the seeds of plants or the ova of animals. Some vegetable-seeds must be planted in one season, some in another; some near to the surface of the ground, others more deeply; some need one soil, others a different one; and while some need a hot sun, others require shade and dampness. As to animals, what a difference exists between the requirements for the fecundation of the ova of fish, of frogs, and of mammals!

In his lectures upon diphtheria, Trousseau recalls such facts as these, and declares, emphatically, *that we ought to be very careful, very sober (très-sobres), in our reasonings against contagion.*

The disease known as hydrophobia—the hydrophobia communicated by the bite of a mad dog—is extraordinary. It is mainly so, however, be it noticed, on account of its horrible characters and its utter hopelessness; for there is nothing uncommon in the bite of an animal being followed by dangerous consequences from the introduction of a peculiar venom, nor is there anything unusual in a

poison acting on particular portions of the nervous system.

Were this disease, however, a thousand times more extraordinary, were it the sole instance known of fatal consequences resulting from an animal virus, we have abundant reason for not denying the fact of its existence from witnesses of whose qualifications, opportunities, and thorough disinterestedness there can be no question. They may, and of course they do, differ about treatment, and about the mode of action of the virus; some, unfortunately, class together under the general head of hydrophobia, cases where there is a simple horror of liquids, those of sympathetic hydrophobia, and those of spontaneous rabies, or rabiform hydrophobia together with those of true hydrophobia from the bite of a mad dog. All agree, however, in regard to the all-important point—the only one here in question—that there is a fearful disease communicated to man by the bite of a rabid animal. That every man who is bitten by a mad dog does not take hydrophobia is a matter of course, for, as remarked above, every seed requires certain conditions for its development; but that some do is a fact in regard to which there must be no question in the mind of a man willing and capable of reasoning correctly. Even if, with foolish reliance upon his own conclusions, a man should try the experiment of suffering himself to be bitten by a rabid animal, and no harm follow, this negative result would not invalidate the thousand positive results in the slightest degree. Everywhere and always—*ubique et semper*—this fact is known. Celsus, Morgagni, John Hunter, Dupuytren, Meade, Chomel, report to us this same fact. And at the present moment there are only too many able and ready to add to this testimony. No one, with such unexceptionable, such overwhelming evidence, must doubt *the facts*.

If any one should choose to uphold such a doctrine as that of the non-contagiousness of rabies as a literary mystification, as a *jeu d'esprit*, like the one of the Archbishop of Dublin referred to, both his judgment and his taste might be called in question. It may well be said that it is in the highest degree improper, for amusement's sake, to teach so dangerous a doctrine as this, that "no such disease as hydrophobia exists or can be caused by the bite of a dog under any circumstances." U. LYSSÉS.

THE PHILADELPHIA MEDICAL REGISTER AND DIRECTORY for 1884 is now preparing, in the hands of Dr. William B. Atkinson, Price, by subscription, \$1.00.

THE ALUMNI ASSOCIATION OF THE JEFFERSON MEDICAL COLLEGE will give an informal reception to Prof. Parvin on the 28th of this month, to which the resident alumni will be invited.

PROCEEDINGS OF SOCIETIES.

COLLEGE OF PHYSICIANS.

A MEETING of the College of Physicians was held December 5, 1883, Dr. ALFRED STILLÉ, President, in the chair.

Dr. JOHN H. PACKARD read a report of a CASE OF ABDOMINAL TUMOR, SOMEWHAT RESEMBLING PREGNANCY, IN A YOUNG MARRIED WOMAN.

I venture to hope that the following report of a case presenting some unusual features may be of sufficient interest to warrant me in bringing it before the College:

Mrs. G., æt. 21, a very slim and delicate-looking woman, consulted me on the 21st of July in regard to a slight and uniform abdominal enlargement, which had been first noticed by her shortly after her marriage about three months previously, and had been gradually and steadily increasing. She menstruated regularly every month, and had had no nausea. Neither the breasts nor the nipples showed any change from the virgin state.

There was no tenderness at any point in the abdomen, and the appearance and feel of the swelling were very much such as would be presented in the early stages of pregnancy.

On the 26th I saw her again, and made an examination per vaginam. The os uteri was soft, and the cervix was of some length; but there was a bulging above, as if the uterus contained a mass partly solid and partly liquid. I did not, of course, think it right at this time to introduce a sound, as, in spite of the absence of rational signs, the presumption seemed to me to be in favor of pregnancy. One fact seemed to militate against this view,—viz., that she rather lost than gained flesh.

I declined to express any opinion as to the character of the swelling, but told the husband that my hope was that the case would prove to be one of pregnancy, as it was likely otherwise to be very grave.

There was a good deal of pain on either side of the hypogastrium, apparently due to tension of the muscles; this was temporarily relieved by the use of chloroform liniment. She had very little appetite, and I gave her a tonic composed of nux vomica and gentian.

The swelling continued to progress steadily, and on September 13 she presented the appearance of being at about the middle of the fifth month of gestation. The hypogastric pain troubled her greatly, and was only allayed for a very short time after each application of the liniment.

At the desire of the family, I now asked and obtained the advice of Dr. Ellwood Wilson, who saw her with me on September 15.

In the forty-eight hours which had elapsed between my previous visit and this one a very marked change had taken place. The abdomen had become greatly enlarged, its walls

forming one curve from the ensiform cartilage to the pubes; there was very decided fluctuation, and percussion showed an area of dulness which was attributed by Dr. Wilson to the existence of a cystic tumor connected either with the Fallopian tube or with the broad ligament. A sound was introduced into the uterus, the cavity of which was found to be unoccupied. Dr. Wilson advised the drawing off of the liquid, which was accordingly done, by aspiration, on the 17th. More than a gallon of ropy, yellow liquid, somewhat deeply tinged with blood, was thus removed; the flow then ceased, and the end of the canula encountered a solid substance, apparently a septum of considerable thickness. Upon the withdrawal of the instrument a fresh flow took place, the liquid spouting out from the orifice to a distance of several inches. When this subsided, the abdomen, which was much less tense, was covered with raw cotton, and a bandage carefully and firmly applied.

During the operation the patient became quite faint, but rallied after the administration of a little brandy-and-water. In the evening her temperature rose to 103.5° , but before morning it fell to about 100° . She slept very little, and complained of much pain, due partly to the stiffening of the cotton and bandage by the agglutination of some of the liquid which oozed from the belly. On examining the wound in the morning, it was found closed.

The following evening the temperature again rose to 103.5° , but subsided again before morning, and was not thereafter above 99° . Yet her condition was unsatisfactory: her face was much pinched and anxious; she had very little appetite or ability to take food; at times her mind wandered slightly, and she slept but little. Vomiting occurred frequently, and she was seldom free from nausea. Her bowels acted regularly; her urine was free, and normal in every respect. Her pulse varied, but was generally from 110 to 120.

Beef-tea, and milk, with brandy and lime-water and champagne, were given at as short intervals as the stomach could bear them, and at stated times. External warmth was carefully kept up.

It was determined that should symptoms of peritonitis present themselves, ovariectomy should be at once resorted to.

A portion of the liquid was submitted to Dr. H. F. Formad for examination, and his report, which was not received until some time after the case had terminated, was, "I think it very doubtful that it comes from an ovarian cyst, the fluid showing very little epithelium and very few of the ovarian cells of Drysdale."

September 23, her condition was very much more favorable; her mind was composed and even cheerful; her pulse and temperature were good. Some food had been taken and retained.

*

On the 24th her state was much the same, and it was thought proper to entertain the idea of an operation for the removal of the supposed ovarian tumor. In the afternoon Dr. Agnew saw her with Dr. Wilson and myself, and it was decided that the attempt should be made on the following day.

Accordingly, on the 25th, at noon, ether was administered by Dr. G. P. Sargent, of Bryn Mawr, and, in the presence of Drs. Wilson and Agnew, I opened the abdomen by an incision in the median line. After dividing the wall, I came to what seemed to be a cyst, and passed in an ovariectomy trocar, when a very free evacuation of liquid, straw-colored and ropy, but clear, took place. It was now apparent that the liquid was contained in the peritoneal cavity, and that there was a large solid mass lying among the intestines. This tumor was soft and doughy, like a placenta; it seemed to belong to the mesentery, since, although somewhat movable, it was firmly attached to the posterior wall of the abdomen, rather high up. The surface of the mass having been slightly lacerated, there was somewhat free bleeding, which was checked with some difficulty by ligation with carbolyzed catgut, and by the application of a cautery-iron.

The wound was now closed with two large pins and a ligature cast around them, and with metallic sutures; a sheet of raw cotton was applied over the whole belly, and secured by a bandage.

The patient rallied considerably, and, after the effects of the ether had passed off, became quite sensible; but she soon began to sink, and died on the 27th, about forty-eight hours after the operation.

No autopsy could be obtained, so that the exact nature and connections of the tumor must remain a matter of conjecture.

The notable points in the case now detailed seem to me to be the occurrence of a solid tumor, probably of malignant character, and apparently connected with the mesentery, in a young woman recently married; its resemblance in its physical appearances to the pregnant womb; the very sudden change that took place by a fresh effusion into the peritoneal cavity, and the obscurity which even then existed as to the real nature of the case. Even with the most accurate diagnosis, effective treatment would have been out of the question; and I cannot but think that my suspicion of pregnancy, erroneous as it proved to be, really prolonged the patient's life, which would have been almost necessarily sacrificed by earlier interference.

CRITICISMS ON THE SPECIFIC THEORY OF HYDROPHOBIA.

Dr. CHARLES W. DULLES read a communication upon hydrophobia, reaffirming the views expressed in a paper entitled "Remarks on Hydrophobia," which appeared in

the *Philadelphia Medical Times*, August 11, 1883. He stated that he was sure that the attitude of severe criticism seems to offer the only hope for the solution of the riddle of hydrophobia; since, in more than two thousand years, the acceptance and repetition of authoritative opinions have failed to furnish a theory which does not fly in the face of all analogy, or a practice which holds out a reasonable hope of saving a single life. Such is the real state of knowledge in regard to hydrophobia. The theories as to its nature are contradictory and illogical; the teachings as to its treatment are without the slightest hope of success. In regard to both, the ablest men who have discussed it occasionally or systematically are in irreconcilable opposition. While some hold to certain modes of communication, others strenuously deny them. While some admit its spontaneous origin, others will not admit it for a moment. While some think the virus is to be found in the saliva, the blood, the bronchial mucus, the milk, the flesh, of rabid animals, others limit it to the first of these alone. In regard to the period of incubation the widest divergence of opinion exists. The range is from one day to forty years, and no one seems to have been able to fix a limit to either its shortness or its length. Equal contradiction meets the gaze when one turns to the matter of treatment. [Here he cited a number of authorities, both ancient and modern, who offer the most varied and even absurd recommendations.]

These citations illustrate the most remarkable feature of the literature of hydrophobia. It would seem as if, when once the mind has accepted a theory which contradicts all experience in other and fairly well understood diseases, it loses the ability to distinguish good evidence from bad. A striking illustration of this is furnished by Dr. Dolan, in his otherwise capital book on "Hydrophobia or Rabies." In his second chapter this writer calls attention in detail to the rules laid down by Dr. Abercrombie in his "Inquiries Concerning the Intellectual Powers and the Investigation of Truth." These warn against the following fallacies: 1. Receiving as facts statements which are not facts, but opinions. 2. Receiving as facts statements which only assume the relation of facts. 3. Receiving as facts general statements, or the generalization of facts. Dr. Dolan then says, "Some writers, for instance, have maintained with much confidence that a particular state of rigidity of some of the limbs is distinctly characteristic of *ramollissement* of the brain. But further observation has shown that the disease may exist without this symptom, and that this condition of the limbs may appear in connection with other diseases. This observation of facts was in so far correct that this state of limbs does very often accompany *ramollissement* of the brain: the error

consisted in giving it as a general fact, or a fact applicable to all cases of *ramollissement*, which is without foundation. Yet such statements, when brought forward with confidence, are often received as facts and rested upon as established principles; and then the facts by which their fallacy might be detected are apt to be overlooked or forgotten." To this reference to the commonest sources of fallacy Dr. Dolan adds, "We are arming our readers against ourselves." And yet he goes on, apparently with his eyes wide open, to reproduce the fault he has just pointed out in speaking of *ramollissement*, accepting statements which ought not to be entertained for a moment in the discussion of so grave and delicate a subject, and admitting as genuine cases which are transparently spurious. Dr. Dulles then gave in detail the report of a case reported by Romberg. This case was declared not to be hydrophobia. He said that he had selected an illustration of the point which he wished to make which should include two names well known and justly distinguished, because their very excellences add force to the proof they furnish that the prepossession of a theory which at the outset demands a certain surrender of the judgment will impair the freedom of the judgment at every subsequent step. Such, it seemed to him, is the condition in which every believer in the specific nature of hydrophobia stands. The assumption of a specific virus, which, and which alone, is the originator of the disease in any individual, compels its adherents to bend their judgment to accept the belief that there is a virus which behaves in a way contradictory to that of every other virus about which we have any positive knowledge. As Lorinser has said (*Wien. Med. Wochenschrift*, 1874), "We know very well the appearances produced, for example, by the bite of poisonous serpents, or by the poisoning of wounds with the poison of glanders, anthrax, syphilis, or cadaveric poison. There are, in general, always the manifestations of more or less rapidly developed inflammation, and of further distribution of the poison through the lymphatics, veins, and lymphatic glands, which organs then, in like manner, manifest similar inflammatory symptoms. Nothing of the kind do we see in wounds made by the bites of mad dogs," etc. And, again, "We know, in all pathology, not a single infective disease which, in regard to the time and symptoms of development, bears the slightest resemblance to hydrophobia."

One might suppose that such a contradiction would lead observers to be constantly on the lookout to find some other way of explaining the phenomena of hydrophobia, and that everything that was presented as evidence in support of it would be subjected to the most rigid scrutiny. But the literature of the subject shows that the very opposite is the case. The *post hoc propter hoc* argument

is the one which rules here. A careful perusal of a large number of recorded cases leaves the impression that they have not been studied with any idea that they might be something else than what they appeared to be. Though it is no secret that the dread of water is a symptom of a great variety of affections, one finds over and over again the ablest men resting a diagnosis on this which is acknowledged by most systematic writers to be the least reliable of its signs. Another thing which had struck them in examining the records of cases is the readiness with which reporters, aware of the objection so often raised of the effect of mental influence, accept the statements of friends or the silence of patients in regard to it as evidence that it does not exist.

Another curious thing to be observed in the literature of hydrophobia is the way in which the madness of the dog is often—one might say usually—deduced from the diagnosis of hydrophobia in the man, instead of the diagnosis of hydrophobia being made to rest upon reliable evidence that the dog was really mad. It is uncommon to find any proof whatever that a dog to which hydrophobia is attributed was rabid, this being, with rare exceptions, a pure assumption. The one phenomenon of a dread of water usually determines the conviction of the physician that he has a case of hydrophobia before him, and settles his opinion of any dog that may ever have bitten the patient and cannot now be accounted for. Nay, more, this mode of reasoning has led certain writers to the assertion that there may be a passing state in dogs in which they may communicate to a human being hydrophobia, but themselves recover. Thus is the struggle to support the specific theory kept up when circumstances seem to be most adverse to it.

Once more, and I am done for this occasion with objections to the anomalies which one meets in examining the basis upon which the general belief in regard to hydrophobia rests. I find in the recorded cases—with very rare exceptions—that, when once hydrophobia is suspected, every phenomenon that occurs during life, every lesion that is found post mortem, is unhesitatingly set down as a feature of this disorder, and the idea does not seem to be entertained that many of them are grounds of suspicion that some other disorder is present. In this way all lines of distinction between hydrophobia and disorders which simulate it are erased, and it remains for every medical man who is called to a patient who has a dread of water, accompanied with exaltation of reflex excitability, to inquire for a bite or scratch of a dog or cat; if one cannot be drawn out, to assume that it has been received and forgotten, then to make a diagnosis of hydrophobia, after which it is only necessary for the patient to die to make a complete record. If to this be

added a careful microscopical examination of the state of the brain and spinal cord, the observer will have an exact counterpart of the process by which the famous conclusions of certain investigators—often quoted by those who have not taken the pains to go to the evidence upon which they are founded—were arrived at.

This suggests a brief consideration of the pathological lesions of hydrophobia. Notwithstanding all the diligent endeavors made to learn something from the post-mortem examination of the bodies of dogs and men that have died of rabies or hydrophobia, one might to-day adopt the language of Dr. Hart, who declares (Cooper's "Surgical Dictionary," art. "Hydrophobia") that these examinations afford "little else than a varied mass of symptoms, common to other nervous and blood disorders," and fail to "throw any clear light on the pathology of the disease."

I will not trouble you with the disappointed anticipations of the ancients in this connection; those of modern times are more instructive. The announcement by Hallier, in 1872, of the discovery of a micrococcus which was the germ of hydrophobia, and to which he gave the positive name of "lyssophyton," and the belief of Klebs in the parasitic nature of the granular elements found around the blood-vessels near the scar, have appeared and disappeared within the last decade. The hasty statement of Pasteur that he had obtained from the saliva of a patient dying of rabies a peculiar germ which, when he had cultivated it and inoculated the product, gave rise to a hitherto unknown disease, he was compelled to withdraw almost as soon as he had made it.*

The investigations of Benedikt, Coats, and Gowers are of the greatest interest in connection with this part of our subject. They are often spoken of as if their results were identical and conclusive, although, in fact, they are neither. Dr. Benedikt published his investigations in 1875 in *Virchow's Archiv*. The text is accompanied with a plate which leaves little room for misunderstanding the author's meaning. The lesions described and figured consist of a perivascular exudation or extravasation (or both) of red blood-corpuscles, miliary spots of finely granular degeneration of the brain-substance, "miliary abscesses," and melting down of effusions so as to make hyaline bodies alongside of the blood-vessels, often closing their lumen; while the vessels had a pigmented encasement (*Pigmenthülle*), made up of red blood-corpuscles. These lesions were found in both dogs and men. Dr. Coats published his discoveries in

* Nothing daunted by the experience of others, I observe that Dr. Paul Gibier reported to the Académie des Sciences of Paris, June 11, 1883, that he had found a special organism in the rachidian fluid of animals that had died of rabies, and that the virus could be attenuated by means of cold. Another of the conclusions he announced at that time was that the disease is communicable from mother to foetus.

the *Medico-Chirurgical Transactions* in 1878, accompanied also with plates. His investigations referred to tetanus and hydrophobia. He makes a point of the analogies between these two disorders, and, assuming a virus in hydrophobia, he argues backwards that there is a poison circulating in the blood in tetanus. The lesions he describes in hydrophobia consist of a perivascular infiltration with *white* blood-corpuscles.

In comparing these investigations, it is to be noted that the lesions Coats found in tetanus correspond much more closely with those Benedikt found in hydrophobia than do those the former found in his investigation of this latter disorder. Further, it is to be noted that he describes the perivascular infiltrate as consisting of *white* corpuscles, while Benedikt is clear in describing it as made up of *red* corpuscles. Finally, Coats does not consider (though most persons who refer to him speak as if he did) the lesions he found to be distinctive of hydrophobia, but simply evidence of irritation in the blood. Thus we see that these two investigators cannot be regarded as confirming each other.

Now, the association of the name of Dr. Gowers (whose investigations are described and illustrated in the *Transactions of the Pathological Society of London*, vol. xxviii., 1877) with those of Benedikt and Coats, as having found lesions pathognomonic of hydrophobia, is equally unwarranted, for he distinctly stated, in answer to a question at the meeting where he demonstrated his specimens (*Lancet*, June 9, 1877, p. 840), that his investigation did not lead him to believe there was any special lesion in hydrophobia.

But, inconclusive and conflicting as the results of all these careful investigations have been, it might be easy to see how they might be taken for more than they are worth, if it were not for the fact that they have been formally and categorically vitiated by the subsequent investigations of others. Thus, Middleton (*Journal of Anatomy and Physiology*, 1881) has published the results of microscopical examinations in which he found perivascular aggregations of round-cells in two cases of hydrophobia, corroborating some of the appearances described by Benedikt, but disagreeing with Coats and Kolesnikoff in essential points. But the most striking point of his publication lies in the fact that he found the same morbid appearances which were present in the cases of hydrophobia, in cases of purpura hæmorrhagica, diabetes, fracture of the skull, erysipelas, head-injury with hæmatoma, concussion of the brain with fracture of the spine, delirium tremens, peritonitis, tubercular meningitis, mental deficiency and excitement, hæmatoma, tetanus, and uræmia. His paper concludes with the distinct avowal that, "As regards the pathology of hydrophobia, it still remains true that nothing characteristic has been observed."

Another investigator, who has gone over this ground, and come to conclusions as destructive as those of Middleton, is Ivanoff, who says (*London Medical Record*, March 15, 1883, from *Vratch*, 1882, No. 15) that similar appearances to those observed by Benedikt, Gowers, and others are found in typhoid fever. One of the supposed characteristics, the transparent spaces, he says, was found by Popoff and Stephanoff in uræmia, and by Vinogradoff in intermittent fever, by Danillo in phosphorus-poisoning, and by himself and Dr. Czorkov in the brains of healthy dogs. They have no pathological character whatever.

But I need not detain you with further references to more or less famous investigations. I will only add that they all tend to confirm the opinion that as yet no gross or microscopical lesion has been discovered which can be regarded as pathognomonic of rabies or hydrophobia.

And now I must close. I have not said so much because it is any pleasanter or is likely to be any easier for me than for others to differ from the majority in the branch of science to which my life is given. It is with shrinking that I take a position which, if it is deemed worthy of notice, will be apt to excite opposition, perhaps condemnation. But I have now been engaged for nearly two years in a laborious study of the evidences upon which the general belief in regard to hydrophobia rests, and I have been gradually led to certain convictions different from those with which I started, and which I feel it my duty to make public. One of these is that hydrophobia is not a specific, inoculable disease, derived from the bite of a similarly affected animal. Another is that if we wish to have an accurate, scientific knowledge of what too often actually takes place, and is usually called hydrophobia, we must begin the study of it unprejudiced by the views heretofore generally entertained in regard to it, and with canons of criticism very different from those heretofore deemed sufficient.

I know that these convictions are not novel, and that they have been stated and defended with arguments before. I know, too, that they have heretofore failed to secure the assent of the greatest men who in every generation have adorned the profession of medicine. None the less, however, do I believe them to be true, and that the time will come when they will not be—as they have been in the past—characterized as too absurd to be discussed, or decried as too dangerous to be tolerated.

But, however that may be, a sense of duty compels me to join myself to the small minority whom I think to be on the right side of the question, for truth's sake. Further, in this matter, the interests of science are in an urgent sense the interests of humanity. For this reason one who feels strongly must speak boldly. This, then, is

my apology to those who may think I have erred in opposing the opinion of so many men deservedly honored and respected in our profession.

THE ANNUAL REPORT OF THE LIBRARY COMMITTEE

showed that there have been added to the library this year 2186 volumes, 2107 pamphlets, and 2862 numbers of journals.

The total number of volumes now in the library is 26,359. For the ensuing year, the library will be kept open, except on Sundays and legal holidays, from ten o'clock A.M. to five P.M.

There are in the collection 3381 duplicates; and particular attention was called to this fact, inasmuch as it affords a rare opportunity to other libraries of augmenting their list at comparatively small expense.

THE REPORT OF THE COMMITTEE ON THE DIRECTORY FOR NURSES

showed that the number of nurses registered

December 1, 1882, was	209
Added during the year	104
Lost by striking from roll	6
Lost by withdrawal	4
Net gain	94

Present number	303
Total number of nurses furnished during the year, 733,—an average per month of 61, as against 49 for last year.	
Largest number (February)	84
Smallest number (August)	34
Sent outside of the city, but within the State	63
Sent to other States	59
Wet-nurses furnished	17
Of registered nurses, there are males	39
“ “ “ “ females	264
Graduates of training-schools	60
Non-graduates	243

The amount given to the library during the last year was two hundred dollars, and for the present year three hundred dollars. Many physicians take great trouble and waste much valuable time in hunting up nurses personally; or, having obtained a good nurse through the Directory, they transfer her from one patient to another directly, instead of through the Directory. Were they to use the Directory, they would obtain the *same* nurses, and add to the income of the Directory, and so to the appropriation to the Library.

It is the desire of the committee to make the Directory also a bureau for all needed information for the sick; and they have in contemplation measures by which, if any one desires to obtain boarding in the country or at the sea-side for cases of whooping-cough, or for recent cases of measles, scarlet fever, or diphtheria, and for information concerning

all appliances of the sick, such as invalid-chairs, wheel and other crutches, bed-rests, fracture-, water-, or air-beds, etc., he may obtain the object he seeks at the Directory.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, December 13, 1883.

DR. J. H. MUSSER in the chair.

Specimen of enormous hypertrophy of the heart. Presented by CHARLES W. DULLES, M.D.

THE patient from whom this specimen was obtained was a young man, 18 years of age, who came under my care in February, 1882, in an attack of muscular rheumatism, principally affecting the shoulders. I found at that time great oppression of breathing, a heart dilated and hypertrophied, with a harsh, strong mitral systolic and presystolic murmur.

Subsequently, albuminuria and general dropsy appeared, with effusion into the abdomen and thorax, and he died with œdema of the lungs.

The autopsy was made with the assistance of Dr. FORMAD and Dr. J. H. MUSSER. The points of interest were as follows. General œdema of feet and legs, the face and neck and chest covered with purpura-like spots and patches. The abdomen contained about two quarts of clear serum; each pleural cavity nearly as much. The lungs were normal, but small, and occupied the upper part of the chest. They were quite œdematous. The liver was slightly fatty. The spleen was of normal size, but very hard and tough. The kidneys were large, congenitally lobulated, and in a state of cyanotic hypertrophy.

The heart was enormously hypertrophied, weighing, when all the adherent parts were removed, forty-eight ounces. The pericardium was so uniformly attached to it that it could not be removed, and there was absolutely no pericardial cavity. The right ventricle contained about six ounces, the left side about two, of soft post-mortem clot. After the heart had been opened and washed, it weighed forty ounces. All the valves and blood-vessels were healthy. The tricuspid and aortic valves were quite competent. The mitral orifice was enormous, measuring two and a half inches across. Every part of the heart was hypertrophied, and all to about the same degree. The whole organ was about the size of that of a bullock.

The points of interest in this case—aside from the curiousness of the specimen—seem to be the comparative immunity of the kidneys, the absence of the physical signs of adherent pericardium during life, the benefit derived from the use of iodide of potash, the temporary disappearance of the very strong

mitral systolic and presystolic murmur, and the parotid swelling following the hypodermic injection of pilocarpine in the arm of the same side.

Dr. J. H. MUSSER, during life, had marked out on the chest the dimensions of the heart, and made it out as enormous, extending especially to the right. Furthermore, he thought that there was a double mitral murmur. The only apparent cause for the hypertrophy was the adherent pericardium. He would like to know what Dr. Henry thought of the correctness of this explanation.

Dr. F. P. HENRY said that the heart presented was remarkable not only for its enormous size, but also for the absence of the usual causes of cardiac hypertrophy, there being neither valvular disease nor obstruction in any part of the circulation. During his student days he had seen some very large hearts in the collection which Prof. Alonzo Clarke was accustomed to show to his class, but he would not trust his memory so far as to affirm that any one of them was as large as the one just shown.

Dr. MACCONNELL had seen a case in a member of the Modjeska troupe, where post-mortem examination showed an enormously hypertrophied heart with adherent pericardium, and markedly granular kidneys. In this case the hypertrophy was clearly due to the kidney-trouble.

Dr. FORMAD said that Dr. Robinson, of New York, had recently reported a case of hypertrophied heart weighing fifty-six ounces, but Dr. Dulles's specimen was weighed after removal of clots.

Dr. MUSSER asked whether other members of the patient's family had not hypertrophied hearts without valvular lesions. If such was the case, taking into consideration the age of the patient, it would be well to consider the probability of the hypertrophy being in part secondary to the pericardial adhesions, in part idiopathic in origin.

Dr. DULLES said that there was a tendency to hypertrophy of the heart in one sister, and that the murmur at times was double.

Calcified pericardium—Double mitral disease.

Ella S., white, æt. 23, was admitted to the University Hospital complaining of palpitation and dyspnoea, and suffering from an œdematous and eczematous condition of the lower extremities. She died three weeks after admission, in a fit of dyspnoea.

Autopsy, seven hours after death.—General dropsy, most marked in the lower extremities and genitals. On the lower part of the abdomen there is a marked varicose condition of the cutaneous lymphatics. The cavity of the pericardium was completely obliterated by adhesions. The two pericardial surfaces, and the fibrous tissue connecting them, had been changed into a calcareous plate three inches broad, completely encircling about its middle

the heart, with the exception of a space one inch wide on the posterior surface of the left ventricle. This calcified condition extended for one inch on the anterior surface of the pulmonary artery. The heart, with the calcified pericardium, weighed twenty-eight ounces. The auricles were dilated, their walls thinned. The ventricles were dilated, their walls thickened and undergoing fatty degeneration. The leaflets of the mitral valve were thickened and rigid; the mitral orifice was very decidedly narrowed. In the inner surface of the left auricle were several calcareous patches. The aorta was very small, scarcely admitting the index finger, and showed patches of atheroma. The lungs were chronically congested and œdematous, the condition being most marked on the left. There was no breaking down of their substance. The abdomen contained five gallons of straw-colored serum. The peritoneum was thickened and roughened. The liver weighed three and one-half pounds, and was cirrhotic. Its capsule was much thickened, and adherent to surrounding structures. The mucous membrane of the stomach was mammillated and thickened. The kidneys showed cyanotic induration.

Section of fibroma mammae. Presented by Dr. W. G. MACCONNELL for Prof. PANCOAST.

The patient was 22 years of age, and the growth was of seven months' duration. Fibromata of the breast are very frequently found, although some English authorities consider them to be of rare occurrence. They have been variously described under different names by writers. Birkett considers them a form of adenoma; Broca, adenoma with predominance of stroma, etc. This tumor was of an ovoid shape, firm and elastic, and on section presented a maroon-colored tissue, which, under the microscope, is seen to be composed of dense bundles of mature fibrous tissue, with but few nuclei. In some portions bands of wavy connective tissue are seen. The epithelial elements of the acini are hyperplastic.

Section of large spindle-celled sarcoma of lower jaw. Exhibited by Dr. W. G. MACCONNELL for Prof. PANCOAST.

The patient was a man, æt. 24 years. The growth had existed for about three years. The egg-shell crackle was readily elicited, the growth being of central origin. On section it presented a whitish appearance, and was traversed by spicula of bone.

Liver of chicken with tubercular growths. Exhibited by Dr. W. G. MACCONNELL.

The microscope clearly proved the nature of the growths.

Dr. FORMAD had seen four or five similar cases in the chicken, and two in the turkey,

in all of which he had detected tubercle-bacilli.

Dr. BARTON was much interested in two of the specimens presented by Dr. MacConnell. He was much surprised as to the nature of the tumor of the jaw, in that it was a spindle-celled and not a giant-celled sarcoma. Its site and duration would clinically have clearly indicated one of the myeloid variety. The sections of the mammary growth differed from those examined by him, in that in adeno-fibroma the glandular elements were more evenly distributed, whereas this section reminded him of his former studies of an elderly normal gland. Such large tracts are found without any traces of gland-tissue, whereas in all adeno-fibromas examined by him the adenomatous and fibrous elements were relatively more evenly distributed, giving the idea of the neogenesis of both, and not the atrophy of one and the proliferation of the other.

NEW YORK COUNTY MEDICAL SOCIETY.

A CALLED meeting was held December 21, 1883, S. O. VAN DER POEL, M.D., President, in the chair.

Dr. H. J. GARRIGUES read a paper on

PREVENTION OF PUERPERAL INFECTION.

The author stated at the opening of his paper that he wished simply to lay before the profession the means by which he had succeeded in freeing the Maternity wards at the Charity Hospital of puerperal fever, leaving out of consideration all theorizing regarding the nature of puerperal fever. Brief allusion was made to the history of antiseptics in obstetrical practice. Dr. Garrigues himself has so far adopted Listerism in midwifery practice, during the past eight years, as to make it a habit to wash the hands and instruments in a carbolic-acid solution, to make vaginal injections twice daily during the first week after delivery, and to wash out the uterus when indicated either as a prophylactic or a curative measure. He carried this plan with him on becoming one of the physicians to the Maternity Hospital. While this hospital has a special board of physicians, it is not an entirely separate institution, but a part of the Charity general hospital; and everybody knows how great the mortality usually is among lying-in women in a general hospital. The following statistics for the Maternity Hospital were read:

	Number of Deliveries.	Deaths.
1875	570	15
1876	536	20
1877	480	32
1878	225	7
1879	254	11
1880	149	8
1881	382	9
1882	431	14

While some of the deaths were attributable to diseases for which the hospital was not responsible, yet the great majority were the effect of hospitalism. During the first nine months of the present year the number of deliveries had been three hundred and forty-five, with thirty deaths. During the first three months of this year, while the author was on duty, the number of deliveries was one hundred and eight, the mortality eleven. Before a recent date it was the exception rather than the rule to see a perfect lying-in period. During six months from October 1, 1882, to March 1, 1883, there were one hundred and ninety-two women delivered, forty-six of whom were seriously sick, thirty-nine with inflammatory puerperal disease. When the author went on duty, October 1 of the present year, the condition of the hospital was at its worst: nine women had died during the preceding month, and half a dozen sick were left over from the preceding service, one of them dying later. In the mean time, bichloride of mercury began to be praised in surgical and obstetrical practice, and he therefore made use of it in the Maternity Hospital. But, not trusting entirely to the virtue of a newly-introduced drug, he adopted several other measures, all of which may have contributed somewhat to the excellent results obtained. At the hospital there are two large wards and one smaller for patients, a delivery-room, a large ward and two tents for the sick. Certain improvements were made in the condition of the wards, and when empty they were thoroughly fumigated with sulphur fumes, the windows then left open day and night, the floors and furniture scrubbed with soap and water, and bichloride of mercury used. The bedclothes were changed. In all the wards large demijohns were placed, filled with bichloride solution (1 to 1000), for use in washing the hands, making injections, etc. It can be used hot or cold, according to indications. When the patient was brought to the delivery-room she was given an enema, and the genitals, the buttocks, and the thighs were washed carefully with a lukewarm solution of the bichloride (1 to 2000). At least two quarts were injected into the vagina by means of the fountain-syringe. The fountain syringe consisted of a glass bucket, a long rubber tube, a straight glass tube for vaginal injections, and a curved one for intra-uterine injections when needed. The tubes were perforated at the end, and there were a number of perforations on the stem near the extremity. In cases of tedious labor, the vaginal injection was repeated every three hours. The rubber sheet covering the delivery-bed was washed with the antiseptic solution just before delivery. In order to limit the danger of infection by examination as much as possible, none of the nurses were allowed to make examinations except the one in charge of the waiting-ward and the head nurse in

the pavilion; and these not to do so oftener than necessary to notify the doctor. The latter was requested not to introduce the finger into the womb, but to be satisfied with an abdominal examination and an examination of the os externum. His hands were to be washed in the bichloride solution, soap and nail-brush to be used. The hands were to be held in the solution a minute or more each time the genital organs were approached. If the hands or instruments were to be introduced into the womb, glycerin was used with the bichloride of mercury (1 to 2000). This was preferred to carbolized oil, as the glycerin itself contained antiseptic properties, which were enhanced by the addition of the bichloride. When the head appeared at the vulva, a piece of lint, soaked in the bichloride solution, was applied, and kept there, for the prevention of the entrance of contaminated air to the vagina. After the expulsion of the child, the genitals were kept covered with a similar compress. The placenta should be expressed, if possible avoiding the introduction of the hand into the vagina. If the hand were introduced, the vagina should afterwards be washed out with the antiseptic solution; otherwise not. On the same principle, intra-uterine injections were employed only when the hands or instruments were introduced, or on the birth of a macerated child. But he never allowed any of the membranes to remain in the womb. The introduction of the entire hand into that organ gives rise to very little danger compared with that of hemorrhage and septicæmia, which are liable to develop if part of the membranes be left behind. In such cases, the intra-uterine injection was given immediately after the removal of the secundines, from two to six quarts of a hot solution being employed. In case of symptoms pointing to possible affection of the uterus, a speculum was inserted, and a careful examination made of the vagina and cervix before proceeding with the uterine injection.

In a case of normal labor the patient was washed with the antiseptic solution. A piece of lint, six inches wide and eight long, folded lengthwise so as to be three inches wide, was placed over the vulva. Outside of that was placed a piece of oiled muslin nine inches long and four inches wide. Outside of that still, came a large pad of oakum; and finally the whole was fastened to a bandage in front and behind by a piece of muslin eighteen inches square and folded together so as to form a kind of boat, pinned in front and behind at each of its corners. This dressing was renewed four times in the twenty-four hours. At the same time the genitals were washed with the bichloride solution. The floor of the ward was sprinkled four times a day with the undiluted solution. In order to prevent infection through visitors, the patient was not allowed to see any person while in

the pavilion, unless death were imminent, when a clergyman was admitted. The doctors and nurses in attendance were not allowed to go into the general wards or into the dead-house.

The instruments were kept in a five-per-cent. solution of carbolic acid, the bichloride being injurious to metal. The patients sometimes complained of a little smarting from the bichloride, and in one case it seemed to produce a slight eruption, which, however, was easily controlled by glycerin. In no case had there been any general symptoms attributable to the mercury. The dressings were continued as long as the patients were in the convalescent ward. They were usually discharged between the tenth and the fifteenth day.

The result of adopting this plan of treatment had been wonderful. As if by magic, all trouble had disappeared from the hospital. Ninety-seven women had been delivered since its introduction, and not only had none died, but there had scarcely been any sickness among them. There had been no trace of diphtheritic inflammation, by which they formerly had been persecuted. Where they used to have offensive odors, feverish and despairing patients, overworked nurses and doctors, the air is now pure, the patients look well, the temperature is normal, the nurses are cheerful, and the doctors happy.

The bichloride has certain advantages over carbolic acid: first, it is a much more reliable disinfectant; second, it is not only free from odor, but it is in addition an excellent deodorizer; third, it affects the skin less; fourth, it is more economical.

DISCUSSION.

The paper being open for discussion, Dr. MURRAY said that he was extremely interested in the paper, as he was Dr. Garrigues's immediate predecessor in the service at the Maternity Hospital, and had witnessed the ravages of puerperal diseases among the patients there. During the three months preceding Dr. Garrigues's last term of service ninety-six women were delivered, fourteen of whom died, eight of puerperal disease. Puerperal fever, as it existed in this hospital, was not like that usually described in text-books: it was more like that which reigned in Bellevue Hospital some years ago. There was a good deal of puerperal diphtheria, usually commencing at the vulva and extending up the vagina, but seldom affecting the uterus. It was usually ushered in with mild symptoms, as a small and frequent pulse, without marked chill, and slight rise of temperature. After the first few days the temperature was liable to become intermittent, being in the morning perhaps 101° F. and in the afternoon 102.5° F. The vulva, being exposed, would show a slight blush, which gradually deepened, and in the course of from one to three days lacerations

OLEATES.

These preparations are salts formed by the union of oleic acid with the respective bases indicated. They are designed for external application, and owe their superiority to the well-known penetrative property of oleic acid. Their medicinal action is entirely dependent on their bases, which are quite readily introduced into the circulation when applied epidermically in this form. As a means of securing the constitutional effects of these bases, their application in the form of the oleates offers many advantages, which will be readily appreciated, especially in the treatment of children and in cases of irritability of the stomach.

Although the advantages to be derived from the combination of bases with oleic acid were recognized as early as 1872, the use of these compounds has not become general, and principally because of defects in the pharmaceutical preparation, the original crude method of their preparation not having been improved upon. Within the past year Dr. J. V. Shoemaker, of Philadelphia, has made the subject of the oleates one of especial study and experiment, both from a pharmaceutical and a clinical standpoint. The result has been the production of a number of very eligible compounds, and the discovery of therapeutic properties hitherto unrecognized. We have secured from Dr. Shoemaker full information touching his methods, and are now prepared to furnish oleates of the following metals, which have been found of great value in the affections indicated:

ALUMINIUM.—A valuable astringent, serviceable in eczema, and as a dressing for burns.

ARSENIC.—This preparation contains twenty (20) grains of oleate of arsenic to the ounce, and is employed as a caustic in the treatment of lupus, epithelioma, etc.

BISMUTH.—An excellent emollient application.

COPPER.—For the treatment of ringworm, etc.

IRON.—Readily soluble in the fats, and use-

ful both as a local astringent and as a general tonic.

MERCURY.—Useful as a discutient to inflammatory exudates, and for the constitutional effect of the metal.

LEAD.—A cleanly and efficient substitute for Hebra's Diachylon Ointment.

SILVER.—An excellent application in pruritus and in erysipelas.

ZINC.—An impalpable powder, and of great value in intertrigo (chafing).

OLEATES OF ALKALOIDS.

OUR LIST OF THESE COMPRISES:

Aconitine (2 per cent. of the alkaloid).

Atropine (2 per cent. of the alkaloid).

Morphine (10 per cent. of the alkaloid).

Morphine and Mercury (5 per cent. morphine and 20 per cent. mercuric oxide).

Quinine (25 per cent. of the alkaloid).

Strychnine (2 per cent. of the alkaloid).

Veratrine (10 per cent. of the alkaloid).

OINTMENTS OF OLEATES.

These contain the several metals mentioned above. They are much more cleanly than ointments as ordinarily prepared, and for all the properties of ointments are much to be preferred.

Circulars fully descriptive of the above, and such other information touching the therapy of the oleates as has appeared, will be furnished gratis on application.

DETROIT, MICH.

BOUDAULT'S PEPSINE.

The only Pepsine used in the Hospitals of Paris for the last 30 years.

Unlike the various substitutes which, in some cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be almost useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 1872, 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy every one that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

With a view of bringing this important remedy within the reach of all, *the price has been materially reduced.* It is now not only the best, but comparatively the cheapest.

In answer to frequent calls, another preparation is now offered,

BOUDAULT'S SACCHARATED PEPSINE,

having the same high digestive power as the amylaceous; it will be sent only when specified.

Boudault's Pepsine is sold in bottles of 1 ounce, with a measure containing exactly 5 grains; also in bottles of 4, 8, and 16 ounces for dispensing.

Boudault's Saccharated Pepsine is sold in bottles of 1, 4, 8, and 16 ounces for dispensing.

Besides Boudault's Pepsine in powder, we offer also

BOUDAULT'S WINE OF PEPSINE.

In this preparation the taste of Pepsine being perfectly disguised, it may be recommended to persons who have difficulty in taking Pepsine in the form of powder.

DR. RABUTEAU'S

(Lauréate of the Institute of France)

DRAGEES, ELIXIR, AND SYRUP OF IRON.

"The experiments made in the hospitals of Paris have demonstrated that *Dr. Rabuteau's Dragees, Elixir, and Syrup* regenerate the red globules of the blood with a rapidity never observed with the use of the other ferruginous preparations. These results have been proved by the various *Compt-Globules*.

"The ferruginous preparations of *Dr. Rabuteau* do not cause any constipation, and are perfectly tolerated by the weakest persons."—*Gazette des Hôpitaux*.

Dr. Rabuteau's Elixir is prescribed when some difficulty is experienced in swallowing the Dragees; it is especially adapted to weak persons whose digestive functions need strengthening or stimulating.

Dr. Rabuteau's Syrup is especially prepared for children, who take it readily because of its agreeable taste.

A sample of Rabuteau's Dragees will be sent free to any physician mentioning THE MEDICAL TIMES.

Prepared by CLIN & CO., Pharmacists, Paris. E. FOUGERA & CO., Agents for the United States.

TANRET'S PELLETTIERINE

FOR THE TREATMENT OF TAPE-WORM (*TENIA SOLIUM*).

This New Tæniacuge, the active alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (*Tænia Solium*). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker, Beaujon, etc., have all been most satisfactory. Dr. Dujardin-Beaumetz, Member of the Academy of Medicine, and Prof. Laboulbène, in their report to the Society of Therapeutics, have given it their unqualified approval after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured. Pelletierine is prepared by

M. CHAS. TANRET, Pharmacien de 1re Classe, 64, Rue Basse du Rempart, Paris.

DUCRO'S ALIMENTARY ELIXIR,

A COMBINATION UNITING THE PROPERTIES OF

ALCOHOLIC STIMULANTS AND RAW MEAT.

This preparation, which has been used with great success in the hospitals of Paris since 1863, is adapted to the treatment of all diseases requiring the administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonary Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE., Paris.

Agents for the United States, E. FOUGERA & CO., NEW YORK.

would be found covered with a grayish membrane. Typhoid symptoms then developed. Different modes of treatment had been resorted to. Carbolic acid had been used extensively; he had used it almost to the extent, in some instances, of producing actual cauterization; yet as soon as the slight coating which it caused separated, the diphtheritic process seemed to develop even in greater severity. He thought that the mortality-rate at the Maternity Hospital had been greater from the fact that certain of the wards had formerly become thoroughly septicized before being used for confinement purposes.

Dr. W. GILL WYLIE said that about six months ago he read a paper before the Society, in which he advocated certain prophylactic antiseptic measures in cases of labor, and since the adoption of this method he had had but a single case in which there was a rise of temperature. It was a case for the use of forceps, and the temperature rose but slightly. He referred to a case which illustrated the necessity of free uterine drainage in puerperal fever, especially after abortion. If necessary, the drainage-tube should be introduced.

Dr. W. R. GILLETTE, who had been physician to the Maternity Hospital for about twelve years, thought that there could be no question in the minds of any present as to the importance of all the suggestions which had been mentioned by the author for the prevention of the development and spread of puerperal fever in the Maternity service. There might be some discussion, however, as to the methods to be employed, although he thought we need not dwell particularly upon these. The bichloride of mercury being the latest disinfectant, he supposed he would have to bow to it and accept it; but it was doubtful whether it ought entirely to supplant others which had stood the test of time. He himself, however, had not used the bichloride. With regard to the dressings employed, he could, perhaps, see benefit in the external dressing, but he could not understand how the compress of oakum and lint, the ordinary Lister dressing, could be of special benefit to the woman in the lying-in hospital, for she moved about in bed, and the dressing could not be kept in close apposition, preventing the entrance of germs from the air. Dr. Gillette referred to the death-rate among the parturients in Bellevue Hospital just before that service was transferred to the Maternity. It had been very great indeed, but so soon as the patients were transferred to the Island, at the Maternity Hospital, into perfectly clean wards, the mortality was reduced almost to a minimum. He believed that the secret of success in lying-in institutions lay in strict cleanliness.

Dr. A. S. HUNTER was quite in accord with the views expressed by the author regarding cleanliness and the use of antiseptics. He

believed, with Dr. Gillette, that the external pad presented by Dr. Garrigues would not succeed in keeping out the germs contained in the atmosphere. He preferred Lyman's silver tube for making intra-uterine injections. He also preferred the Davidson syringe to the fountain syringe, as with it the water could be thrown in in jets. He believed that antiseptic methods could be carried out with ease, even in detail, in obstetrical practice. He used intra-uterine injections only when there was special indication therefor, as in septicæmia. A napkin wrung out of the antiseptic solution and placed over the genitals was sufficient.

Dr. SIMON BARUCH offered his unqualified condemnation of the practice of antiseptic injections after normal labor and for prophylactic purposes. Out of nine hundred cases of midwifery he had seen but one death preceded by febrile symptoms, but since commencing the use of antiseptic vaginal injections after labor he had seen quite a number. He quoted statistics by German authorities who had given the method a thorough trial, and they went to show that much better results were obtained by simple attention to cleanliness, without any disturbance of the patient by injections or otherwise. The danger of removing clots and opening up the mouths of vessels to absorb poisonous matter, of injecting the fluid directly into the sinuses, of injuring the lining membrane of the genital tract, of forcing the fluid into the peritoneal cavity, etc.,—these were all dangers attending injections, as had been shown by actual experience.

The paper was further discussed by Dr. F. V. WHITE, Dr. GERRISH, and Dr. J. C. PETERS, and the discussion was closed by the author.

NEW YORK PATHOLOGICAL SOCIETY.

A REGULAR meeting was held December 26, 1883, GEORGE F. SHRADY, M.D., President, in the chair.

DILATATION OF THE STOMACH.

Dr. JOHN C. PETERS related a case of enormous distention of the stomach, occurring in a female, who had become much emaciated, and was in the habit, after retaining her food for two or three days, of throwing it up by the basinful. It was vomited in a fairly well digested condition. A small tumor could be felt, supposed to be located near the pyloric orifice, and believed to be the cause of obstruction to the farther passage of the food. The œsophageal tube was not introduced, the patient's low condition not permitting. She complained of great discomfort on being turned from side to side. He had seen a similar condition in two other cases, each of them females, and in each there being a tumor.

Dr. VAN GIESON recalled a case in which the stomach was so greatly distended that its outlines were recognized at the ensiform cartilage and symphysis pubis. Dr. Flint believed distention to be due to stricture of the intestine, but the autopsy showed no other cause than probable paralysis. The patient had become greatly emaciated.

Dr. R. W. AMIDON had seen three cases of supposed dilatation of the stomach, and he was unable to withdraw anything through the stomach-pump except some mucus. He also referred to a case which suggested the question whether floating kidney was usually attended by albuminuria.

Dr. G. L. PEABODY replied that he had examined something like three thousand kidneys at autopsy, and had not seen a single case in which he could say that there was truly a floating kidney. He was therefore inclined to think that some mistake had been made in the comparatively numerous examples of floating kidney so diagnosticated of late. At any rate, there is not a sufficiently large number of authenticated cases to enable us to draw any general conclusions as to the condition of the urine.

ENDARTERITIS OBLITERANS IN EPITHELIOMA.

Dr. G. L. PEABODY presented a penis, together with a microscopical section, in a case which was specially interesting as being a good illustration of the condition called endarteritis obliterans. The patient was a man 71 years of age, who first noticed a pimple on the frænum, which went on to develop into ulcerative epithelioma, necessitating amputation of the organ. A microscopical section showed connective-tissue development in the intima of the blood-vessels, as seen in cases of endarteritis obliterans in the brain. Dr. Peabody had seen the condition as frequently in non-syphilitic as in syphilitic subjects, and in different parts of the body, occurring in chronic phthisis and chronic nephritis, as well as in epithelioma.

MILIARY ABSCESES OF THE KIDNEYS.

Dr. BEVERLY ROBINSON presented a specimen, obtained from a woman, a domestic, who died in the Charity Hospital. She was admitted August 31, 1883, in a condition of emaciation, and of pregnancy at about the third month. She had incontinence of urine, accompanied by pain on its passage. Sweating and chills developed, with vomiting; the urine contained pus. Abortion took place at the fifth month. A few hours later she died of exhaustion. At the autopsy the lungs were found to be œdematous, with some adhesions at the posterior aspect of the apex of the right lung. The heart was normal. The liver weighed seven pounds, and contained fatty deposits. The kidneys weighed nine ounces each, and their surfaces were studded

with miliary abscesses. The bladder was normal. No tubercular deposits were to be found, nor were there metastatic abscesses elsewhere.

Dr. PEABODY doubted whether it could be said with certainty, with the symptoms given, that there had not been some septic influence, nor that the apparent abscesses were not tubercular.

Dr. ROBINSON also showed a specimen in which a communication existed between the pleura and the lungs, constituting a kind of valve, which would illustrate the possibility of the existence of such an opening without there being at the same time an interchange of fluids.

PYELONEPHRITIS AND ITS EFFECT UPON SURGICAL PROCEDURES.

Dr. JOHN A. WYETH presented specimens removed from a man who died in the hospital with cystitis and signs of hectic. He was 26 years of age, and had some time before been operated on for hemorrhoids, and cured. But three months later he returned, with frequent desire to pass urine, and later he developed high temperature. At the autopsy the kidneys were found the seat of pyelonephritis, constituting very fine examples of that condition. The ureters were distended. The bladder was greatly thickened from chronic cystitis. The latter condition had so overshadowed the kidney-symptoms that recently an operation had been attempted for drainage of the bladder. When operating for hemorrhoids, some time before, ether was administered, and the patient came near dying under its influence. On the occasion of doing cystotomy chloroform was administered, and scarcely had the external incision been made when the heart stopped, respiration ceased, and it was with some difficulty that the patient was made to rally. The operation was not completed. Dr. Wyeth prefers the lateral operation to the median. Sir Henry Thompson had spoken favorably of cystotomy in the treatment of chronic cystitis.

Dr. GERRISH said he had done the operation in one case with benefit.

Dr. PEABODY thought that an important question arose in these cases, important because difficult to answer,—viz., the possibility of excluding disease of the kidneys, or pyelonephritis.

The PRESIDENT thought that in such cases, in which there was pyelonephritis and consequent danger in administering an anæsthetic, cystotomy should not be performed.

Dr. WYETH thought the patients should have the benefit of cystotomy, notwithstanding the presence of pyelonephritis, and, if the operation were attended by some risk, that risk had better be assumed than allow the patient to suffer without any attempt at relief.

GLEANINGS FROM EXCHANGES.

THE ABUSE OF ALCOHOLIC LIQUORS.—Dr. James E. Reeves, Secretary of the West Virginia State Board of Health, makes the following well-timed protest against the constant use of alcoholic beverages, in an address before the Public Health Association, on the "Eminent Domain of Sanitary Science, etc.":

"The popularity of the milder alcoholic beverages—ale, beer, and wine—is directly due to the influence of our adopted fellow-citizens in all classes of society. I should be untrue to myself, to my position, to the medical profession, and to humanity, if I let this opportunity pass without sounding a note of warning against the intemperate use of alcoholic drinks, and to speak of their influence to debase the citizen and his progeny—physically, morally, and mentally—and deny him and them good health and longevity.

"The connection between drunkenness and crime, and between drunkenness and poverty, is close, and unvarying in its effect upon society. The remarkable increase of insanity in recent years may, in part, be traced to the prevalence of the intemperate use of intoxicating liquors. That wine, beer, and the stronger beverages, when taken in excess, all tend to derange the mental manifestations, is a fact too familiar to medical men to require of me argument to prove its truth. They act upon and disorder the brain more directly, perhaps, than any other organ, and, by habitual excess, may at last induce permanent impairment of the mental faculties.

"In times of epidemic visitation—when pestilence is sweeping the country—the intemperate and the drunkard are the first to fall by its arrows of death; and the chances of recovery from any disease or injury whatever are infinitely less for the drunkard than for the sober man. Were man to live as he should do,—*enjoying every good gift and abusing none*,—he would (saving accidents) live to extreme old age without disease. But, alas! how many such careful, prudent, temperate lives could there to-day be found in this great country of ours, where a kind Providence has made it possible for us to enjoy every blessing the whole world can afford? The denunciation by the prophet Isaiah—"Woe to the drunkards"—"*Woe to them that are mighty to drink wine*"—is not only in course of fulfilment every day with the drunkard, but the *curse* extends to his children yet unborn, even to the third and fourth generation, by inheritance of appetites which are far more constant and certain in their descent than patrimony.

"It has been asserted that at least seven-tenths of all the crimes and poverty and calamity to the people of the United States spring from the abuse of personal liberty in

the use of spirituous, vinous, and malt liquors; and if the charge be true—either in whole or in part—it is a subject which should concern sanitarians. Vice needs every possible exposure and discouragement to prevent its seeds from growth, and the lesson should everywhere be taught, that good health and long life cannot dwell in association with a poisoned mind or an upbraiding conscience."

CHLORATE-OF-POTASH POISONING.—Drs. Broesicke and Schadowald report a case (*Berliner Klinische Wochenschrift*, No. 42, 1883) of rapid poisoning by chlorate of potash in a healthy young man, aged 22. After excessive and incautious gargling with a strong solution for some trifling-throat affection, in the course of which he had swallowed a considerable quantity, the patient complained on the following day of sickness and of pain in the sides and loins. Signs of acute gastritis rapidly followed; nausea and severe pain in the splenic region were the chief symptoms. Some enlargement of the spleen could be detected. Heart and lungs were normal; but distinct cyanosis, especially of lips and extremities, was present. Two days after the poisoning severe vomiting set in, and lasted to the end. Icterus followed, but disappeared before death. On the fourth day, severe epistaxis occurred; extreme præcordial anxiety followed, but without any notable signs in heart or lungs; and some rigidity of the muscles of the extremities was observed. Death took place on the eighth day. Throughout the whole period of illness hardly any urine was passed; the temperature remained a little below the normal; the pulse, however, was of fair strength. The post-mortem examination, made four days after death, revealed a brown discoloration of the blood in the vessels. The blood, however, gave the normal appearance to the spectroscope. The spleen was very greatly enlarged, brownish in places, the capsule soft. The kidneys were also enlarged, the cortical portions expanded and of a dirty-green color. Microscopically, the straight and convoluted tubules were found filled with numerous brownish, irregular-shaped masses of hæmoglobin. The stomach showed acute and chronic catarrh, with a few ecchymoses. The large intestine and rectum contained a large quantity of brownish, watery fluid, and the mucous membrane appeared cedematous. Other organs normal.—*Medical Times and Gazette*.

DEATH FROM HEART-CLOT IN A FATTY HEART AFTER ETHERIZATION.—An interesting case is reported by Prof. Minot, of a single lady, 45 years of age, who had a right-sided pleural effusion, for which ether was successfully administered on October 15, and nearly two quarts of bloody serum were withdrawn. The chest having refilled, ether was again administered November 16, preparatory to a second paracentesis. The pa-

tient took the ether well, but when about a pint of the effusion had been withdrawn she became livid, and her breathing irregular and gasping. She was revived with difficulty, and two hours later she seemed quite recovered; subsequently the dyspnoea and lividity returned, and the patient died, asphyxiated, eight hours after the beginning of the etherization. An examination of the body showed a fatty heart, with a white clot extending from the right auricle into the pulmonary artery. She also had cancerous pleuritis and peritonitis.—*Boston Medical and Surgical Journal*, December 13.

MISCELLANY.

HYDROPHOBIA.—The Brown "Animal Sanitary Institution" (under the government of the University of London) has issued a notice, in which it is said that hydrophobia occurs in dogs of all ages, and may appear at any season of the year. It is recognized by a change of demeanor of the dog, which becomes dejected, morose, inclined to roam, and anxious to hide itself. The animal gnaws at wood, stones, and any refuse which it sees, snaps at imaginary objects, and becomes unusually excited by strange or sudden noises. It rubs its throat with its paws, as if striving to get rid of some object lodged there; at the same time there is a more or less abundant flow of saliva from the mouth. The dog will attack its master, or animals of any kind; but it is most easily roused to fury by the presence of other dogs. There is throughout the disease no dread of water. In one form of the disease, called "dumb madness," there is paralysis of the jaw, and therefore inability to bite. If a dog has shown any of the symptoms of madness, it should be at once loose-muzzled and securely chained up. Owners of dogs are warned of the danger they may incur by allowing their face and hands (especially if scratched) to be licked by the animals, even if these show no sign of madness. All dog-bites should be immediately cleansed by suction and washing, and the wounds should be cauterized as soon as possible.—*St. Louis Druggist*.

NOTES AND QUERIES.

MEMORIAL NOTICE OF DR. T. S. KIRKBRIDE.

The notice published in our last issue should be corrected in so far as it states that Dr. Kirkbride moved with his family into the new hospital building when it was opened. This, we are informed, was not the case; but he continued to occupy the mansion on the grounds for the Department for Females, in which he lived from 1841 up to his death. The Department for Males is in the new building; the old one is still devoted to the uses of the Department for Females. The following tribute to the memory of Dr. Kirkbride, which

appeared in the *Philadelphia Evening Bulletin*, is worthy of preservation:

IN MEMORIAM.

T. S. K.

Died December 16th, 1883.

O rare and radiant life, whose mission here,
Like some strong angel's winged with love divine,
Waited on human woe, to heal and cheer,
What high, unselfish, tireless zeal was thine;
To fan, with tender care, the flickering spark
Of waning reason and the shattered will.
To find the missing clue, where all is dark,
And guide to hope and light with patient skill;
True pity thine which clasped each clouded heart,
Nor on the lowliest ever looked askant.
Swaying distempered minds with sovereign art,
Gentle as woman, firm as adamant;
Nor less shall memory keep the tranquil grace
Of look and tone and bearing, staid and calm,
The sweet serenity of form and face,
Home's dearest solace, friendship's kindest balm.
By this new grave no broken shaft we rear:
Thy finished work has followed thee above,
One step from duty, midst the shadows here,
To the full sunshine of eternal love!

W. A. B.

CHRISTMAS, 1883.

RESOLUTIONS ON THE DEATH OF DR. WILLIAM H. HOOPER.

At a meeting of the Executive Committee of the Wood Medical Journal Club, held December 21, 1883, it was

"Resolved, That in the death of Dr. William H. Hooper this Club, in common with the medical profession of the city of Philadelphia, has lost a member conspicuous alike for the breadth of his culture, the soundness of his judgment, and the urbanity of his manner.

"Resolved, That we recognize in his acknowledged success as a practitioner the merited reward of long years of patient study, preliminary to, as well as during, his special preparation for professional life.

"Resolved, That a copy of these resolutions be sent to the family of the deceased, and to the *Philadelphia Medical Times*, *Medical Bulletin*, and *Medical and Surgical Reporter*."

(Signed) W. R. D. BLACKWOOD,
Secretary,
BENJAMIN LEE,
Chairman.

For the Committee.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM DECEMBER 22, 1883, TO JANUARY 5, 1884.

APPEL, DANIEL M., CAPTAIN AND ASSISTANT-SURGEON.—

Having relinquished the unexpired term of leave of absence granted by S. O. 68, Headquarters Division of the Atlantic, November 16, 1883, and reported for assignment, assigned to duty at Fort Porter, New York. Paragraph 2, S. O. 247, Department of the East, December 29, 1883.

HAVARD, VALERY, CAPTAIN AND ASSISTANT-SURGEON.—

Assigned to duty in charge of office of Medical Director Department of Texas, during the temporary absence of that officer. Paragraph 2, S. O. 164, Department of Texas, December 31, 1883.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY FROM DECEMBER 29, 1883, TO JANUARY 5, 1884.

Medical Director A. L. GIBON to the Naval Hospital, Washington, D.C.

P. A. Surgeon CHARLES W. RUSH, U.S. steam-ship "Colorado," granted sick leave for three months.

Medical Inspector A. HUDSON from duty as Assistant to the Bureau of Medicine and Surgery, on the 18th inst., to the U.S. steam-ship "Lancaster," as the relief of Medical Inspector F. L. Bates, who is to be detached and ordered home.

P. A. Surgeon A. C. H. RUSSELL from the Navy-Yard, Washington, to hold himself in readiness for sea-service.

PHILADELPHIA, JANUARY 26, 1884.

ORIGINAL LECTURES.

CLINICAL LECTURE

ON REMITTENT FEVER COMPLICATED WITH HÆMATURIA AND TYPHOID SYMPTOMS—THE TREATMENT OF RHEUMATISM.

Delivered at the Philadelphia Hospital

BY JAMES TYSON, M.D.,

One of the Physicians to the Hospital, and Professor of General Pathology and Morbid Anatomy in the University of Pennsylvania.

Reported by WILLIAM H. MORRISON, M.D.

GENTLEMEN,—In the case that I shall bring before you to-day there are some rather unusual features, which require study. The history is as follows. The patient, a laborer, 28 years of age, and a native of Ireland, was admitted to the hospital October 11, 1883. He says that he has been temperate, and denies all venereal history. He was well up to the summer of last year, at which time he was working in New Jersey, and had malarial fever. This continued for two months. In September last he again had chills and fever. On the 1st of October he was exposed to rain, and this exposure was followed by diarrhoea and a feeling of exhaustion. When admitted into the wards, the diarrhoea was slight, but he passed large quantities of dark-colored urine.

It is evident from this history that the man has had malarial fever; but the symptoms which he presented on admission were also of a kind to suggest typhoid fever. But, after watching the temperature and other features of the case for a few days, it became evident that this diagnosis could not hold. I wish to-day to call attention to the points in this case and discuss them with you, and draw such conclusions as may appear justified.

In the early part of the attack the patient had diarrhoea. When I first saw him, he had a dry, coated, leathery tongue. These, with a more or less constant feverish condition, are the suggestive symptoms alluded to; but careful examination of the abdomen failed to reveal the presence of the characteristic spots of typhoid fever. Even if this eruption, which usually appears about the eighth day, be not

present, the temperature-record will in ordinary cases enable the diagnosis to be made. The course of the temperature in typhoid fever is as follows: there is always an evening rise and a morning fall; but, as the temperature is recorded day after day, it is observed that the evening temperature is always a little higher than that of the previous evening, and each morning temperature a little higher than that of the previous morning: so that we have a tidal rise in the temperature, which in the course of the second week reaches its maximum. As the diagnosis in this case was not positive, the temperature was carefully taken twice a day. October 12th, A.M., it was 100.4°; P.M., 103.2°; 13th, A.M., 98.6°. This was altogether unexpected. Instead of being higher than the previous morning, it was two degrees lower. On the evening of the 13th the temperature was 100.6°, higher than the morning temperature, but still considerably less than the previous evening; 14th, A.M., 100°; P.M., 100.4°; 15th, A.M., 99°; P.M., 100.6°; 16th, A.M., 98.4°; P.M., 98.2°; 17th, A.M., 98.4°; P.M., 100.4°. It is not necessary to go further with the reading of the temperature. It is at least evident that there is nothing of the nature of a tidal rise. On the other hand, there is quite a constant morning temperature, which by evening has gone up to about 100°. It is clear that this is not a case of typhoid fever. There is another symptom in this case which does not belong to typhoid fever: there is more or less constant bloody urine. I can account for this condition on no other ground than that it is malarial in its origin. There is no undue frequency of micturition, and no evidence of disease of the bladder or of the kidneys.

The only conclusion to which I could come, in view of these facts, was that our patient's disease was essentially malarial fever of the remittent type, with typhoid symptoms, and might be called typho-malarial fever.

Now, there are two ways in which this term may be applied. In the first place, that disease may be called typho-malarial fever in which there is malarial fever complicated with typhoid symptoms, or the term may be applied to cases in which the two diseases exist together,—that is, typhoid fever running *pari passu* with ma-

larial fever. A third application of the term typho-malarial fever has been made; that is, to indicate a special form of fever with its own morbid anatomy, distinct from that of typhoid fever and of malarial fever. But this idea, which originated with Dr. Woodward, of the army, has been given up. Can we in this particular instance settle this question? Can we say whether it is a case of malarial fever with a typhoid complication, or whether it is a case in which typhoid and malarial fevers are concurrent? In the first place, there can be no doubt that two general diseases may coexist in the same individual. You have probably all heard of measles and scarlet fever running their course together. Some diseases are nearly always associated, as, for instance, pneumonia and pleurisy, and pneumonia and bronchitis; but I am now referring more particularly to general diseases.

There is, therefore, no reason why we should not have malarial fever and typhoid fever concurrent. But let us discuss somewhat further the grounds on which we conclude that such is not the case in the present instance. This patient has been under observation for twenty-one days. As a rule, a case of typhoid fever either becomes decidedly convalescent or else ends fatally by the end of the third week. In the course of the third week the temperature begins to fall, and there is a tidal decline. The morning temperature is a little lower than that of the previous morning; the evening temperature a little higher than the temperature of the morning of the same day, but a little lower than that of the previous evening. If this were a case of typhoid fever, we should expect it to show some disposition to terminate. In point of fact, during the past week the symptoms have become aggravated. His dry tongue had, under the use of turpentine, become moist, and all the symptoms, excepting the hæmaturia, had improved; but last week they became aggravated, and the temperature rose decidedly. On October 24th and 25th the temperature was normal. On the 26th it began to rise, and reached 103° . The next day it was in the morning 103° , and in the evening 104° . Since then the temperature has not been below 100° until the evening of October 31st, when it was 98.4° .

These symptoms, however, suggest a re-

lapse in typhoid fever. You are aware that relapses in this disease are not infrequent; but when typhoid fever relapses it repeats its previous history. The spots, diarrhœa, and peculiar temperature recur. But there has been no diarrhœa; there are no spots on the abdomen; there is no tympanitis; neither is there marked abdominal tenderness. This case does not give us a repetition of the symptoms of typhoid fever, and we cannot consider it a relapse. I feel constrained to class this as malarial fever of the remittent type; for, as you see, there is more or less continuous fever. There are also typhoid symptoms, so that in one sense of the term it is a case of typho-malarial fever; but it is not a case of concurrent typhoid and malarial fever.

As we were under the impression, when he was first admitted, that we had a case of typhoid fever to deal with, he was placed upon a treatment which would really answer for both diseases. In the first place, I always begin the treatment with quinine for a few days, for it is often impossible to tell at first whether a fever is malarial or typhoid. Sixteen grains of quinine per day, continued for four or five days, will have the effect, in the first place, of keeping up the powers of resistance of the patient, and, in the second place, will remove any malarial element. We used quinine in the present case, and the symptoms were much improved. On account of the condition of the tongue, I also ordered ten drops of turpentine four times in the twenty-four hours. We made no local application, as is our custom in typhoid fever, in the form of poultices and turpentine stupes. Under this treatment he improved decidedly. Last week we suspended the treatment, and in the result of this suspension of treatment we have another evidence of the malarial nature of the disease. As soon as the treatment was stopped, all the old symptoms returned. We again returned to quinine and turpentine; but during the past twenty-four hours the administration of these remedies has been interfered with by "hic-cough."

The treatment of this symptom has therefore claimed our attention exclusively during this period. Sometimes it is a mere nervous symptom, which a more powerful nervous impression will cause to disappear. At other times it becomes a severe and

obstinate complication. You all perhaps recall the treatment for the hiccough of our childhood,—that is, the taking of three swallows of water without interruption, which is the substitution of one nervous impression for another. Hiccough is a spasmodic contraction of the diaphragm, with sudden closure of the larynx. A variety of remedies have been recommended: one of the best is counter-irritation in the region of the diaphragm. A large mustard-plaster will often answer the purpose. If counter-irritation fails, morphia, in doses of one-quarter of a grain three or four times a day, may be employed. Failing in this, chloroform, in the form of the spirit or tincture, may be employed in doses of half a teaspoonful every three or four hours. Hoffman's anodyne is sometimes employed with advantage. Nitrite of amyl is also given with satisfactory results. In administering this remedy, the little glass pearls should always be used, one of them being crushed in a handkerchief and the drug inhaled. Another remedy which has considerable reputation in hiccough is musk. As it is doubtful whether we can now procure pure musk, it is not administered as often as it formerly was. Chloral in combination with bromide of potassium is an excellent remedy. The order in which, under ordinary circumstances, I would use these remedies is the following: counter-irritation with mustard, chloral, opium, chloroform, Hoffman's anodyne, musk, and finally a blister, as we have done in this case. The hiccough has been somewhat improved since the application of the blister. It is intermittent, lasting for a few hours, and then disappearing for several hours.

During the last few days there has been gradual improvement. The fever has diminished, and the amount of blood in the urine has lessened. This is a specimen of the urine last passed. From its appearance, only, it would be impossible to say whether or not it contains blood. A small quantity of blood in an acid urine gives the liquid a smoky hue, of which this is a fair representation. Sometimes the urine is perfectly clear. This is characteristic of malarial hæmaturia.

We have come to the conclusion that this is a case of remittent malarial fever with typhoid symptoms. As to the cause of these symptoms, it is difficult to say. He may be the subject of septic conditions

resulting from his residence, habits, or other causes. Typhoid fever is a form of septic fever, resulting from the absorption into the blood of putrid poisons; but there may be other forms of manifestation of septic fever than the symptoms of typhoid fever. This man may have had introduced into his system septic matters giving rise to the symptoms which he has presented.

THE TREATMENT OF RHEUMATISM.

I shall devote the few remaining minutes of the hour to the consideration of a case of rheumatism. He gives the following history. He is 37 years of age. Seven years ago he had typhoid fever, and five years ago he had rheumatism in the left shoulder, hand, and foot. The present sickness began in December, 1882. While cutting ice, he became wet, and remained in his wet clothing for half an hour. The next day he was taken sick with fever. The right wrist soon became swollen. The swelling next affected the right ankle, and then the left ankle. Looking at his wrists, you observe a peculiar deformity, which is due to accumulation of fluid. In other words, these joints are the seat of rheumatic synovitis. The joints of the feet are also affected. The early history of this case is typical of acute articular rheumatism. The form of exposure which preceded the development of the acute symptoms is that which is peculiarly prone to develop acute articular rheumatism. I refer to exposure to cold and wet combined. The swelling and pain left one joint to appear in another. This is characteristic of rheumatism. He has never been well since this attack developed, but the acute symptoms have subsided, and there is now a condition of subacute rheumatism.

When taken sick, he sought no advice but that which he could gain at a drug-store. He was given something to take internally, and a liniment to rub the affected joints. This is just the sort of treatment we should expect to be followed by the chronic form. It used to be said that the best cure for rheumatism was "six weeks," by which was meant that there was no remedy which was of especial service in this affection, and that under ordinary circumstances it would get well of itself in six weeks. Although this may have been true then, it is not true at the present time. There is no doubt that we

have in salicylic acid and the salicylate of sodium remedies which greatly increase our power over rheumatism. We now take hold of a case of acute rheumatism with the greatest confidence. In my own experience I do not recall a single case of acute articular rheumatism coming under observation at an early period in which salicylate of sodium failed to bring about a cure. If this man had been properly treated, he probably would not have been here to-day.

My method of giving salicylate of sodium is to administer ten grains every two hours, and continue this until the pain has disappeared and the swelling diminished. After the disease has yielded, it does not do to stop the treatment, but the remedy must be continued for ten days or more, ten grains being given every four hours.

Salicylate of sodium is not the only remedy of service in acute rheumatism, and there are certain conditions which call for a modification of the treatment. When the patient has not been in a condition of previous good health, but has been depressed by unfavorable hygienic surroundings, it is often necessary to combine iron with the salicylic acid. At times iron alone is sufficient.

After a case has passed into the sub-acute form, as in the present instance, how is it to be treated? Is salicylic acid of any service in this condition? It may be, although less certainly than in acute rheumatism. At the same time, I am apt to begin the treatment with salicylic acid; but the method in which I have most confidence is that by counter-irritation with fly-blisters. A blister one or two inches square should be applied over the various joints in succession, and the counter-irritation kept up for weeks. In a case like this it is not always necessary to resort to so formidable a remedy as blisters. Painting the parts with iodine will sometimes cause absorption of the fluid and the disappearance of the symptoms. The internal use of iodine and iodide of potassium is also resorted to in these cases. Iodide of potassium may be given in doses of ten grains three times a day, or Lugol's solution may be substituted and continued for a considerable length of time.

The question has probably arisen in your minds, Is salicylate of sodium of service in what is called muscular rheumatism? It is not nearly so useful in this

affection as in acute articular rheumatism. Although I have known it to be occasionally of service in such cases, the best treatment in my experience for muscular rheumatism is dry and moist heat, and moist heat in the majority of cases. This form of heat is obtained by the use of hot baths. I have recently used, with much satisfaction, hot soda-baths, in which from half a pound to a pound of washing-soda is added to an ordinary bath of hot water. This should be taken on going to bed. The use of dry heat is also of service. One of the most annoying forms of muscular rheumatism is the ordinary stiff neck. The best remedy for this condition is a gum bag filled with hot water, on which the neck should be laid on going to bed. In the majority of cases the pain will have disappeared before morning.

ORIGINAL COMMUNICATIONS.

A NEW METHOD FOR DETERMINING THE AMOUNT OF BLOOD THROWN INTO THE ARTERIAL SYSTEM BY EACH VENTRICULAR SYSTOLE, AND FOR ESTIMATING THE TIME REQUIRED FOR THE CIRCULATION OF THE BLOOD.

BY ROBERT MEADE SMITH, M.D.,
Professor of Comparative Physiology, University of Pennsylvania.

FROM the time of Santorini (1724) various attempts have been made to determine the quantity of blood thrown out from the heart at each contraction of the ventricles.

Santorini, followed by Legallois (1824) and Colin, estimated the cubic contents of the chambers of the heart by filling them after death, before the onset of rigor mortis, with a fluid of known density, and assumed that the amount so determined coincided with the quantity of blood propelled by the heart at each contraction during life. But this method, as well as that employed by Brücke (1850), Hiffelsheim, and Robin (1864), of making wax casts of the chambers of the heart after death, is open to the objections that nothing is positively known as to whether the ventricles completely empty themselves in their systole or not, or under what pressure they are filled: the importance

of a consideration of the latter point will be referred to later.

Nor can the observations of Abegg (1848) be regarded as throwing any additional light on this subject. He opened the thorax of a living animal and ligated all the vessels at their origin and termination in the heart, the arteries being first closed: the heart was then excised and weighed, and, after allowing the contained blood to escape, was weighed again, the loss of weight giving the weight of the blood. It is, however, manifestly unwarrantable to assume that this amount was evenly distributed among the four chambers of the heart; while, even if we waive this objection, and further assume that each cavity was filled under its normal tension, the experiment does not assist in determining the amount of blood thrown out at each contraction, especially since Sandborg and Worm-Müller have shown that it is by no means certain that the ventricles completely empty themselves during systole.

Volkman in 1850 reckoned the capacity of the ventricles in the following manner. He first estimated the velocity of the circulation in the carotid by means of his hæmodromometer (a thoroughly unreliable method), and then the cross-section of the aorta: from these data he calculated how much blood passes through the *aorta* in a unit of time. If, then, the amount of blood in the body be known, the time necessary for its complete circuit can be calculated; and, if the number of pulsations of the heart in this time are known, the amount thrown out at each pulsation is readily reached.

It is seen, however, that the cornerstone of this argument rests upon an accurate determination of the velocity of the circulation in the aorta, a quantity of such great variability, as shown by Ludwig and Dogiel, as to render the statement of any estimate of its average velocity entirely unjustifiable; and when it is remembered that Volkmann's estimate of even this quantity was reached from measurements made on the *carotid*, the unreliability of his conclusions is still further emphasized.

Vierordt's method is based upon the same principle as that of Volkmann, and is therefore open to the same objections.

More recently, Fick (1869) has attempted to estimate in man the rapidity

of the circulation, and the amount of blood thrown out at each contraction of the heart, by measuring by means of the plethysmograph the increase in the volume of the arm at each cardiac systole. By this means, however, he was able simply to determine how much more blood was forced into the axillary artery than escaped within the given time-unit through the axillary vein, and not the absolute amount of blood forced into the arm. In order to supply this deficiency, he assumed that the variations in rapidity of circulation in man coincided with the measurements made by Chauveau, Berthollus, and Lavayenne on the horse, and constructed the point of equilibrium in the vessels of the arm from an observation of Marey on the alterations of the rapidity of the circulation in the carotid of the horse. By this plan, knowing the ratio between the lumen of the axillary artery and that of the aorta, he was able to calculate the amount thrown out during systole of the left ventricle. His estimate, however, falls far below that of the majority of observers: thus, Fick's estimate was about 76 c.c.; Krause's, 160 grms. (obtained by measurement after death); Volkmann's, 187.5 grms.; Vierordt's, 180 grms.

It is worthy of notice that as yet no attempt has been made to measure directly during life the quantity of blood thrown out by the heart, and it is evident that any method by which this amount can be so determined must give far more accurate results than one depending on such uncertain data as those heretofore employed. The method which I employed last summer in the Leipsic Physiological Institute, under the direction of Prof. Ludwig, renders this possible and promises to yield valuable results. The present communication, however, is only to be regarded as a preliminary note.

The plan of the research rests upon the diversion during life of the entire arterial blood-current, directly after leaving the left ventricle, into a reservoir of known capacity, then into the right heart, then to the lungs, and finally again to the left ventricle: so that, while the pulmonary circuit remains undisturbed, a vessel in which the rapidity and volume of the arterial stream can be measured is substituted for the systemic circulation.

The great bulk of the arterial system

was obliterated by passing a flexible rubber catheter, terminating in a small rubber bulb, through the left axillary artery into the descending aorta, so that the bulb occupied a position directly below the arch of the aorta. In the undistended condition, the catheter and bulb, being so much smaller than the calibre of the aorta, did not materially interfere with the normal blood-supply of the trunk and lower extremities: this was always tested by measuring the blood-pressure in the vessels of these parts by means of a manometer connected with the femoral artery. As soon, however, as the bulb was distended by injecting water through the catheter, the blood-pressure, as measured in the femoral artery, instantly fell to zero, showing a complete occlusion of the dorsal aorta; while, from the position of the bulb, which was always verified by post-mortem examination, the only arteries still remaining patulous were the coronaries and the two subclavian and carotid trunks, with their branches. This can be made evident by reference to the diagram of the great vessels in the dog, the animal always employed in these experiments. It is there seen that immediately after leaving the arch of the aorta, the subclavians (or, more strictly, the axillaries, as the dog has no clavicle) give off four large arteries, the vertebral, the profunda, the mammary, and a muscular branch. These vessels are ligated on both sides of the neck, so leaving only the carotids to carry blood to the brain during the intervals of the experiment.

If now a canula be inserted in the right axillary artery on the proximal side of the ligature, and connected by tubing with a canula in the right external jugular vein, the carotids being occluded by loops and the bulb in the aorta distended, all the blood driven out by the left heart at each pulsation will be forced into the jugular vein, and so into the right heart. It then only remains to determine the amount of blood passing through the connecting tubing in any given unit of time, which quantity, divided by the number of pulsations in the same time, will give the amount of blood forced out from the heart at each pulsation.

The instrument which I used to measure the flow of blood through the right axillary artery was a modification of Ludwig's rheometer (stromuhr). The essential parts of this instrument (see fig.) are two

communicating glass vessels (*a* and *b*), whose cubic contents from the constriction at *c* to the constriction at *d* are accurately known, inserted in the metal disk *f*, which is capable of being rotated through half a circle on *g*. The tubes *h* and *h'* communicate at one end with the bulbs *a* and *b*, and at the other with canulæ inserted in the blood-vessels, the apparatus being so arranged that the blood-current enters at *h*; the bulb *a* with its tube, and the tube *h* up to *c'*, are filled with defibrinated blood, while the bulbs *h*, *h'*, and *b*, and the connecting tube *l*, are filled with oil. When the blood from the artery is allowed to enter *h*, it forces the oil in *b* before it over into *a*, while the blood contained in the latter enters the blood-vessel through *h'*: when the bulb *b* is entirely filled with blood, the bulbs *a* and *b* are turned through a half-circle and the process repeated. It is then only necessary to know the time required to fill either bulb to know the quantity of blood flowing in that time through the artery.

It was found in my earlier experiments with the ordinary form of stromuhr that the force of the blood-current was so great as to drive the blood in jets through the oil contained in the bulbs, instead of gradually displacing it and thus rendering it impossible to determine the exact time when the bulbs are filled. After testing various modifications in the form of the stromuhr, the following seemed to overcome this difficulty: a T-tube was inserted into *h*, the cross-arm of which communicated with a metal capsule whose top was formed by a rubber membrane; the elasticity of this membrane served to overcome the intermittent force of the pulse and to render the stream continuous, besides greatly reducing the resistance of the stromuhr.

The shape of the stromuhr was further modified, as shown in the diagram, so as not only to break up the force of the entering blood-stream, but also to permit a more accurate estimation of the time at which the bulbs were filled. The bulbs were also made much larger than in the earlier form. The stromuhr was further so arranged that each time the disk was turned through a half-circle it alternately opened and closed an electric circuit passing through an electro-magnetic lever writing on the revolving drum of the kymographion.

DIAGRAM OF GREAT VESSELS OF THE DOG, AND ARRANGEMENT OF APPARATUS.

ax, axillary artery; *m*, mammary artery; *v*, vertebral artery; *p*, profunda colli; *mb*, muscular branch; *spv*, superior vena cava; *jv*, right external jugular vein; *c*, carotid arteries; *mn*, manometer; *t*, metal capsule with rubber membrane; *r*, rubber bulb of catheter. In order to avoid complication, the arrangements for turning the stromuhr and for opening and closing the recording electric circuit are not represented.

Method of Experimentation.—In some cases the dogs were first narcotized with chloral; but this, combined with the peptone that was subsequently injected to prevent coagulation, seemed to increase the fatal tendencies of the latter, and several experiments failed on this account. In other and more satisfactory cases the animals were chloroformed during the operation, and then allowed to regain consciousness before the peptone was given, the latter being sufficiently narcotic to prevent pain and to keep the animal motionless.

The first step in the operation, after performing tracheotomy, was to insert a canula into the crural vein, for the injection of the peptone solution, and then to connect the crural artery with a mercurial

manometer to determine the time at which the aorta was occluded.

An incision was then made on the right side of the neck, a little above and parallel to the first rib, all vessels lying in the course of the incision being divided between two ligatures, and the axillary artery exposed where it crosses the first rib, carefully raised with a blunt hook, and all its branches tied. The success of the experiment depends upon the occlusion of every branch given off by the axillary artery: as already stated, these are usually four in number. The right external jugular vein is then isolated well down in the neck, its branches tied, and a loop placed around it. This loop, as well as the one around the axillary artery, is not tied until the last moment, so as to pre-

serve the circulation unaltered as long as possible, and to prevent the formation of clots.

The right and left carotid arteries are then isolated and surrounded by loops.

The left axillary artery is then exposed and its branches tied as in the case of the right. On this side the operation is more difficult, from the deeper seat of the vessels, and there is more danger of wounding the pleura.

For every kilo of body-weight of the animal three cubic centimetres of a ten-per-cent. solution of pure peptone in half-per-cent. salt solution are then injected into the femoral vein, to prevent coagulation of the blood. The first effect of this injection is to cause a marked temporary reduction in blood-pressure from vasomotor paralysis; the measurement of the flow through the aorta is not attempted until the vessels have nearly regained their normal tone; the blood remains incoagulable for several hours.

Glass canulæ of the same diameter as the blood-vessels are then inserted into the right axillary artery and jugular vein, filled with defibrinated blood, and connected with the tubes of the stromuhr, which had been previously filled, as described, with defibrinated blood and oil.

A small T-tube is then inserted in the left carotid artery, on the proximal side of the loop, and connected with a Fick's spring manometer to measure the pressure in the stromuhr and to count the pulsations of the heart. The object of the T-tube is to permit the free supply of blood to the brain in the intervals of the experiment. The catheter and bulb are then inserted through the left axillary artery and pushed to their proper position, determined by measurement, in the aorta.

The manometer in the carotid and the electric marker of the stromuhr write in a vertical line over a seconds time-marker on the revolving drum of a kymographion.

The bulb in the aorta is then distended, and as soon as it is certain that the aorta is occluded, the loops on the carotid are elevated and the stromuhr turned so that the blood enters it from the aorta. As soon as the bulb is filled, the stromuhr is turned and the operation repeated until the oil and blood become so mixed that the time required to fill each bulb can no longer be accurately determined. The animal is then killed by injection of cu-

rare, and the heart immediately excised and placed in a ten-per-cent. solution of sodium chloride to prevent coagulation of the myosin of the heart-muscle; rigor mortis is thus prevented.

The two coronary arteries are then ligated, the greater part of the left auricle cut away, and a wire ring stitched to the free edge of the remaining portion, and, after destroying the semilunar valves, a graduated glass tube bound into the aorta. The heart is then re-immersed in a ten-per-cent. salt solution until all the cavities are filled with the liquid, when the heart is suddenly elevated so as to close the mitral valve. The fluid on the outer surface of this valve is then removed with a pipette, and that in the aortic tube withdrawn with a siphon until the level of the aortic orifice is reached. The siphon is then pushed down to the apex of the ventricle and its contents drawn off and measured; by this means every drop of fluid in the ventricle can be drawn off and the cubic contents of the cavity so determined compared with the quantity thrown out at each pulsation during life.

The pressure, therefore, to which the ventricle is subjected when its capacity is measured after death is zero, because, as shown in Goltz and Gaule's experiment, there is a negative pressure in the left ventricle during its diastole, and because, as shown in Experiment I., the slight increase of pressure on the walls of the ventricle caused by a column of salt solution of 39 mm. in height is capable of increasing the capacity of the ventricle by one-third.

The following are the details of some of the experiments made after this method:

Experiment I.—The stromuhr without rubber capsule was employed; its resistance was estimated at 130 mm. mercury. The blood-pressure in the carotid, after closure of the aorta and all blood-vessels with the exception of the two vertebrals, which by mistake were left open, was 135 mm. mercury. Respiration was natural throughout the entire experiment.

The average number of heart-beats required to fill each bulb was 12, and, as the bulbs contained 123 c.c., the quantity thrown out at each pulsation was about 10 c.c. This coincided with the cubic capacity of the left ventricle as measured after death, viz.:

Capacity of the heart under 0 mm. ten-per-cent. salt solution pressure = 10 c.c.; under 28 mm. salt solution pressure = 11.5 c.c.; under 35 mm. salt solution pressure = 13.5

c.c.; under 39 mm. salt solution pressure = 15 c.c.

Experiment II.—Dog: chloralized and peptonized; artificial respiration. All the vessels were correctly ligated, and the rubber bulb of the catheter occupied its proper position in the aorta. The stromuhr with rubber capsule was employed; its resistance estimated at 10 mm. mercury. Pulse recorded with Fick's manometer in connection with the carotid.

First Series.

Observation.	Pulsations.	Time.	Amount expelled at each beat.	Heart-rate per min.
1	53	24 sec.	$2\frac{17}{53}$ c.c.	132
2	43	18 sec.	$2\frac{37}{43}$ c.c.	140

Second Series.

5	30	12 sec.	$4\frac{1}{10}$ c.c.	150	—

Cubic contents of left ventricle = 16 c.c., zero pressure. Weight of dog = 12½ kilo.

Several conclusions may be drawn from these experiments.

In the first place, it is seen that the amount of blood thrown out by the heart is by no means a fixed quantity, and that measurements made of the capacity of the ventricles after death have no value in this connection: the only instance in which these quantities were at all approximate is seen in the first experiment; but in this case, from an accidental disarrangement of the apparatus, the pulse had to be counted in the jets of blood in the stromuhr. An error could thus easily have been made.

As a rule, more blood is expelled from the left ventricle when the rate of pulsation of the heart is slow than when rapid. This is well shown in Experiment IV., where, in the first observation, 12 c.c. were thrown out at each beat, the rate of pulsation of the heart being about 110 per minute; while, when the heart-rate was increased to 150 per minute, only $4\frac{1}{10}$ c.c. were expelled. These are two extreme cases. The other observations serve to confirm this statement. It is also to be expected that the character of the respiration would influence the quantity of blood leaving the ventricles, or, more properly, entering them.

When artificial respiration is employed, the aspirating effect of the lungs is not only lost, but the dilatation of the heart is hindered by the positive pressure exerted on its walls by the lungs; the heart will, therefore, fill itself incompletely, and therefore discharge less blood, while the rate of pulsation will ordinarily be increased. This state of affairs is seen in the latter part of Experiment III.

In these experiments the amount of blood leaving the left side of the heart has been alone measured; but, of course, all that has been said of the left ventricle applies equally to the right, since they must propel equal amounts of blood simultaneously. For, were the right ventricle to discharge the most, as has been claimed by Colin, the blood must eventu-

ally collect in the lungs; while, if it discharged less than the left ventricle, the blood would stagnate in the systemic capillaries.

These experiments will also serve to throw some light on the time required by the blood for making one complete revolution of the body.

The method most generally accepted as giving a correct solution of this problem is that first employed by Hering, and afterwards by Pousseuille, Vierordt, and Blake: it consists in injecting a solution of ferrocyanide of potassium into one jugular vein, and then determining the time elapsing before the salt can be detected in blood taken from the jugular vein of the other side.

As determined by this method, the time required for making the complete circuit of the body in the dog was 15.22 seconds (Vierordt); or, as expressed as a general law, the circulation requires for its completion, in all groups of mammals, twenty-seven pulsations of the heart (Vierordt).

Now, taking the most favorable circumstances for the testing of the truth of this statement, it is seen in Experiment IV. that the greatest amount thrown out at any one contraction was 12 c.c., and the weight of the dog was 15.5 kilo. If we accept the statement of Heidenhain, that the amount of blood in the body of an average dog is one-thirteenth of its body-weight, the animal experimented on in the above instance must have contained about one kilo of blood, or, the specific gravity of blood being 1050-1060, from 950 to 940 cubic centimetres of blood. It would therefore require seventy-nine or seventy-eight pulsations of the heart to propel the entire amount of blood once around the circuit of the body; the pulse being 110 in a minute, it would require, therefore, forty-three seconds to complete the circulation in the dog.

It should, moreover, be noticed that the example taken is the one in which the largest quantity of blood was propelled at any one time, and is therefore most favorable to the statement of Hering.

It is evident, therefore, that in the method employed by Hering, although it has given tolerably constant results in the hands of different observers, there must be some factor concerned other than the mere mechanical propulsion of the blood. Some experiments of Pousseuille

seem to throw some light upon this point. He found, as quoted by Matteucci, that there was a marked difference in the time required by different substances to complete the circuit, even though they were given in quantities small enough to be without effect on the force or number of the heart's pulsations. Thus, while the ferrocyanide of potassium was detected in eighteen seconds in the horse, when a little alcohol was added to the ferrocyanide the latter did not escape from the opposite jugular vein until after forty to forty-five seconds. It seems probable, therefore, since we know that different liquids brought into contact will diffuse into one another with different degrees of rapidity even when the masses of the liquids are at rest, that Hering's results are partly to be attributed to the physical laws of diffusion, and not solely to a mechanical propulsion of the blood.

Moreover, it is well known that in all cases of movement of fluids in tubes, the portions of the fluid in the axis of the tube move with a higher velocity than the portions nearer the walls of the tube. By Hering's method, however, it is this highest velocity alone which is measured; his results cannot, therefore, be applied to the solution of the question as to how often the entire mass of blood passes through the heart, or, in other words, how often in any given time the venous blood becomes arterial.

Since writing the above, my attention has been called to an abstract of a paper by Drs. W. H. Howell and F. Donaldson, Jr.,* on the "Maximum Volume of Blood sent out by the Left Ventricle in a Single Beat, and the Influence of Variations in Venous Pressure, Arterial Pressure, and Pulse-Rate on the Work done by the Heart." In this paper they give the results obtained on the heart of the dog isolated after Professor Martin's method. Some of their conclusions seem to be at variance with the results described in my paper; but, as the detailed account of their experiments has not yet been published, this discrepancy may be merely apparent.

A READY METHOD FOR THE DETECTION OF THE BACILLUS TUBERCULOSIS.

BY M. B. HARTZELL, M.D.

SINCE Koch first announced the discovery of the bacillus tuberculosis, methods for its detection have multiplied rapidly. Most of these methods, however, are more or less complicated, are uncertain, and require too much time in their execution to be of use clinically.

On account of its simplicity, and of the short time required to execute it, I wish to add another to the many staining processes already in use. This process appears to me to possess decided advantages over all others with which I am acquainted: by means of it the sputa of patients who are supposed to be tuberculous can be easily and rapidly examined, and the bacilli are so deeply stained that if any are present in the specimen under examination they cannot be overlooked, if ordinary care is used. The process is briefly as follows. A small quantity of sputum is spread as thinly and evenly as possible upon an ordinary glass slide; it is allowed to dry, which takes but a minute or two, and is then passed slowly several times through the flame of an alcohol lamp or Bunsen burner. One or two drops of the fuchsin solution, recommended by Gradle, and prepared as follows,—carbolic acid, $\mathfrak{M}\mathfrak{xv}$; distilled water, $\mathfrak{f}\mathfrak{3ss}$; dissolve, and add saturated alcoholic solution of fuchsin, $\mathfrak{f}\mathfrak{3ss}$,—are placed upon the sputum thus prepared, and allowed to remain from three to five minutes. The slide is now washed thoroughly with distilled water, to remove the excess of fuchsin, and the stained sputum completely decolorized by means of a saturated solution of oxalic acid. It is again thoroughly washed in distilled water, after the decolorization, and allowed to dry: it is now ready to be mounted in glycerin or balsam for examination. With a power of five hundred or six hundred diameters the bacilli will appear as brilliant red rods, no staining of the background being necessary.

In all other methods with which I am familiar, the decolorizing agent employed is dilute nitric acid; but this, besides being disagreeable to handle because of its corrosive and staining properties, is apt to remove the color from the bacilli too, unless great care is taken. Oxalic acid, how-

ever, seems to leave the dye untouched in them.

To render the process still clearer, the different steps may be arranged thus:

1st. Spread the sputum upon the slide, dry, and pass through the flame of the lamp.

2d. Stain with the fuchsin solution three to five minutes.

3d. Wash in distilled water.

4th. Decolorize with oxalic acid.

5th. Wash again thoroughly in distilled water, dry, and mount in glycerin or balsam.

3721 SPRING GARDEN STREET, PHILADELPHIA.

REPORT ON RECENT PROGRESS IN GYNÆCOLOGY AND OBSTETRICS.

DEVELOPMENT OF UTERINE MYOMATA.

KLEINWACHTER* considers that the process of development of uterine myomata is not yet satisfactorily known: it is not probable that it is the result of hypertrophy of muscular fibres, but the round fibres are transformed into fusiform fibres which cannot be distinguished from muscular fibres. The matter of inquiry is to learn if the round cells are derived from the connective tissue or from the division of the cells of the muscular tissue. Small tumors are better for study, because in the large ones the development is complete, or else it is difficult to find points in which it is in progress. The author has found pure myomata or fibro-myomata in which the connective tissue is in excess of the muscular tissue, but he has never found a pure fibroma. The fasciculi cross each other in every direction, and lie closer together than in the normal state, and the cells and nuclei are a little larger and longer than in the non-gravid uterus. The myoma is generally distinctly separated from the neighboring tissue because of its connective-tissue capsule, or the direction which the fasciculi of its structure follow.

The author believes that many of these tumors are arrested in their development, although it cannot be claimed that this arrest is final. In case of multiple tumors, each has its capsule of connective tissue, or a thick layer of normal muscular tissue. Kleinwachter has never seen new vessels

* Zeitsch. f. Geb. und Gyn., ix. 1; Annales de Gynécologie, December.

in a myoma; but he has seen them in a fibro-myoma.

CASTRATION OF WOMEN.

In a recent paper by Tauffer,* the author presents the following conclusions:

1. This operation, made with proper precautions, does not present great dangers; the inevitable mortality is only ten per cent.

2. Make it under spray: close the abdomen; drainage only exceptionally necessary.

3. The patient's being near the menopause is not a contra-indication, for it cannot be predicted when the menses will finally cease.

4. It is not possible to follow the rule of Hegar,—that is, that the ovaries must be accessible to palpation.

5. Double ovariectomy is to be done, even when the second ovary is not diseased, save in exceptional cases.

6. Remove the oviducts if they are diseased.

7. Hystero-epilepsy is curable by castration.

8. The symptoms of which the association has received the name of hysteria are in many cases to be attributed to an ovarian malady.

9. The question of ligating large nutritive vessels passing to a fibro-myoma is worthy of consideration.

10. As to prognosis, it is probable that the menopause will promptly follow the operation, except when the neighboring organs have become inflamed; such inflammations delay the critical age.

11. The result cannot generally be judged until some months after the operation.

12. The question of the influence of diseases of the genital organs upon certain psychoses is matter of study.

13. The same is true as to the effect of castration upon the psychoses.

14. For our instruction, it is desirable that the cases of castration may be classified according to the plan proposed by Hegar.

THE INFLUENCE OF PUERPERAL EPIDEMICS UPON THE TIME OF LABOR.

M. Hervieux† made a communication to the Académie de Médecine, in which he

remarks that a certain number of pregnant women are susceptible of contracting a puerperal septicæmia which sometimes causes premature labor, and this septicæmia may be developed, with all its characteristics, after the premature expulsion of the foetus. But these familiar facts were regarded as exceptional. On the other hand, Hervieux holds it to be exceptional that when a pregnant woman is in an infected atmosphere she is not infected. He had been led to this conclusion by statistics taken at the Maternité during twelve years. By these statistics it is shown that premature labors were in proportion to the intensity of puerperal affections. With improvement in the sanitary condition, the number of premature labors and of maternal deaths underwent a corresponding diminution. In his treatise on abortion M. Garimond has asserted infection and contagion as very probable causes of abortions, without, however, giving the clinical proof, and this proof is now made by Hervieux. The longer a pregnant woman sojourns in an infected medium, the greater the liability to premature labor; and therefore in a time of an epidemic every maternity should be closed, and, no epidemic existing, pregnant women ought not to be admitted until as near as possible to labor.

A theoretical consequence is obvious, and that is that the placental wound is not the avenue of entrance of the puerperal poison, or at least the sole way by which it enters. In the pregnant woman the uterine cavity is closed, and consequently there is no internal surface comparable to a wound, no gaping mouths of vessels, and therefore no point accessible to the septic principle.

LESSENING THE DURATION AND THE PAIN OF NATURAL LABOR.

Dr John Morris, of Baltimore, discusses‡ the question as to means that can be judiciously used to shorten the term and lessen the pain of natural labor. Dr. Morris advises, when the first stage of labor is slow, and interference advisable from the delay, or from other cause, detaching by means of the finger the membranes from around the cervix. If premature rupture of the membranes occur, dilate the os with the finger, carefully swept round it during a pain. Where delay in dilata-

* Zeitsch. f. Geb. und Gyn., ix. 1; Annales de Gynécologie, December.

† Archives Générales, December.

‡ Journal of the American Medical Association.

tion is caused by rigidity of the os, morphia hypodermatically, or opium by the mouth. In unequal spasmodic contractions, use Braun's colpeurynter. If, the os being moderately dilated, the cervix is narrowed like a band, use Barnes's dilators.

According to Dr. Morris, though the os may be pretty well dilated, labor may be delayed by the firmness, dryness, and want of distensibility of the vagina: in this condition he advises copious injections of hot water, and, if this should fail, introduce a cotton tampon saturated with glycerin and lard. If inertia is present, one or two drachms of fluid extract of ergot are given; when there is arrest of the head from an occipito-posterior position, the forceps is needed. When the head is in the pelvic cavity, and the os dilated, it may be, only to the size of half a dollar, and the labor is lingering, rupture the membranes, draw the os forward during pain, and use strong external pressure. The author remarks, "Ergot is not generally necessary in this condition, but if the pains are ineffectual its administration is most beneficial,"—advice the latter part of which, the reporter begs leave to suggest, almost justifies the radicalism shown by some of the members of the American Gynecological Society at its last meeting, who thought it would be a blessing if ergot were banished from obstetric practice. When the head has descended to the perineum, and the labor lingers, ergot and external compression; but if delivery does not take place speedily, the straight, Beatty forceps.

ATTENTION REQUIRED WHEN THE LOCHIAL DISCHARGE IS NORMAL.

A very interesting paper by Dr. Eustache, entitled "*Études sur les Lochies dans l'État normal et les États pathologiques*," has recently appeared in successive numbers of the *Archives de Tocologie*. We present an abstract of the directions Dr. Eustache gives as to the care of the lochia when this discharge is normal:

The accoucheur ought to inquire as to the number of napkins used since his last visit: he learns the abundance, the color, and the odor of the lochia. If the flow is too abundant, if blood continues beyond the third or fourth day, and especially if there be a decided odor to the discharge, his attention is to be directed to modifying these characters.

The genital parts are carefully washed

after delivery; this washing to be done with simple warm water, or with water containing a small quantity of carbolic acid. A napkin is placed over the vulva, and at the end of an hour changed for a clean one, and then a little less frequently as the flow lessens. Each time that the nurse removes the napkin she must be careful to wipe thoroughly the external parts, so that they may not remain soiled; she ought also to separate the labia, so as to free the vulval orifice of any obstructing clots. Morning and evening she will complete this toilet of the external genital parts by washing them with warm water, or, better, with warm water made aromatic by the addition of a little vinegar or cologne water.

The accoucheur ought to see that there is a free discharge of the lochia, guarding against the retention of clots in the vulva or in the vagina, and direct that the napkin shall not be so closely applied that it acts as a plug. Position ought to be made to intervene to assist the lochial flow. Except in some cases of post-partum hemorrhage, or of threatened syncope, it is always preferable for the patient to be in a slightly-inclined position; that is to say, let the head and upper part of the trunk be raised somewhat by pillows, for the purpose of favoring by gravity the flow of the lochia, thus avoiding their accumulation and remaining in the vagina. The patient may usually be allowed to turn from one side to the other, either in eating or in nursing her infant. From the second day she may take her meals in a sitting position: the vagina will thus be naturally emptied of its contents.

It ought to be remarked that the most dependent part of the genital organs is not the vulva, but rather the deep part of the vagina corresponding to the neck of the uterus; and that the neck is very frequently the seat of rents, and if it is constantly bathed in the lochia it may be the medium of septic absorption. In surgery we use drainage-tubes to favor the flow of pus; in obstetrics the parts are sufficiently disposed to spontaneous drainage, provided absolute immobility is not observed. Vaginal injections are not employed unless the lochia have a decidedly bad odor. Dr. Eustache then uses carbolized water; but he remarks that he looks upon the injection as detersive rather than antiseptic.

If the flow does not cease to be red the third day, especially if it continues red the fourth and the fifth day, it is necessary to find out the cause; and generally it will be found to depend upon imperfect retraction of the uterus. Under these circumstances, ergot is to be given by the mouth; ergotin hypodermatically is objectionable, for it may cause erysipelas. It is almost a rule that the first getting up, especially when it takes place about the seventh or the eighth day, is followed by a return of the red flow. This phenomenon tells us that the retraction and restoration of the uterus are far from being complete, and is an indication for rest in bed.

When the lochial discharge is prematurely diminished or suppressed, this condition is not in itself an indication for therapeutic means. While this suppression is not to be regarded as a primary morbid state, and therefore efforts to recall the flow are to be condemned, therapeutics should be directed to the different morbid states, to the various local or constitutional maladies which may exist.

Retention of the lochia may result from spasmodic closure of the os uteri, or from cedematous swelling of the labia majora and of the nymphæ. An examination with the finger will readily detect the retention from the latter cause, and the flow is thus readily restored.

NON-PUERPERAL PELVIC LYMPHADENITIS AND LYMPHANGITIS.

Dr. Mundé* has an interesting paper having this title. He rests his diagnosis of the affection described on the shape, size, tenderness, mobility, and number of the nodules, on their relation to the uterus (not being directly connected with it, but still not entirely independent of it), on a condition of the uterus which might readily produce inflammation or enlargement of the adjacent glands, the mobility of the uterus, and, finally, on the acknowledged presence of some lymphatic glands and numerous lymphatic vessels in the connective tissue surrounding the supravaginal portion of the neck. Dr. Mundé states that the points he desires to make in his paper are the following:

1. That an inflammation of the pelvic lymphatic glands and vessels occurs in the non-puerperal state far more frequently than is generally supposed.

2. That such inflammation generally becomes chronic, and very closely simulates so-called chronic pelvic peritonitis and cellulitis, both in symptoms and in physical properties.

3. That such lymphatics in a state of chronic inflammation possess certain characteristic features which permit their recognition by the examining finger.

4. That this inflammation may either depend on and be secondary to uterine disease, or be entirely confined to the lymphatics and be apparently idiopathic.

5. That the treatment resembles that of chronic pelvic inflammation, with one exception,—the primary necessity for the removal of the focus of irritation, if such exist, before the lymphatic inflammation can be permanently removed.

INFLUENCE OF DIPHTHERIA UPON PREGNANCY.

Dr. Auguste Ollivier,† at the conclusion of a paper upon this subject, observes that diphtheria may be a cause of abortion, and therefore when it occurs in a pregnant woman may have exceptional gravity. The abortion is due, in a large number of cases, not to asphyxia or to the high temperature of the blood, but to an alteration of this liquid which, though badly defined, cannot be disputed. The possibility of abortion, with its dangers, therefore, suggests the importance of isolation when pregnant women are in a ward where diphtheria occurs.

OBSERVATIONS UPON THE PATHOLOGY OF PREGNANCY-VOMITING.

Dr. Griswold,‡ after considering the various theories of the vomiting of pregnancy suggested by Hewitt, Bennett, Sims, Copeman, and others, holds that the opinion that this disorder is caused by uterine deviations from a healthy condition is not correct. He regards the fact of pregnancy as the cause in the vast majority of cases, and says that "the practitioner who loses sight of this old view in his study of the newer lights may be led into unnecessary errors of surgical treatment in a great many cases which would be much more sensibly cared for by easier and more agreeable means."

TRANSLATIONS.

THE ANATOMICAL CAUSES OF HERPES ZOSTER.—Lesser reports the microscopical appearances found in the post-mortem examination of a third case of herpes zoster, in which he was able to confirm the statement, based on two previous cases, that the disease is a consequence of nervous disturbance. In this case, during life the herpes was situated in the distribution of the fifth, and partly of the fourth, right intercostal nerves. On post-mortem examination, the fifth intercostal nerve was strikingly thinner than normal, flattened, and of a transparent reddish-gray color, forming a strong contrast to the white of normal nerve-tissue. Similar changes were found in the fourth intercostal nerve, but less marked than in the case of the fifth. Microscopic examination showed that numerous fibres of the fifth intercostal nerve had undergone degeneration, and that the fifth intercostal ganglion had in its upper half lost its normal structure, the nerve-elements being replaced by connective tissue. Similar changes, though less marked, were found in the ganglion-cell and fibres of the fourth intercostal ganglion, though no degenerated fibres could be found in the corresponding nerve.

In relation to the connection between the nervous lesions and the skin affection, the author believes that, either through the irritation of certain nerves or from their loss of function, microscopical points of necrosis form in the deeper layers of the skin and then extend to the surface, and that reactive inflammation follows as a consequence of this necrosis.—*Centralb. f. d. Med. Wissen.*, December 1, 1883. S.

THE ETIOLOGY OF TABES DORSALIS.—In the study of his second hundred of cases of tabes dorsalis, Prof. Erb makes the following statement as regards the etiology of this disease. Of these cases there was only nine per cent. in which previous syphilitic infection could not be proved; with positive secondary syphilitic symptoms, sixty-two per cent.; with chancre, but without definite secondary symptoms, twenty-nine per cent.; or, in all, ninety-one per cent. of these cases possessed a syphilitic history. In relation to the time elapsing after syphilitic infection before the appearance of tabes, he found that in sixty-nine of these ninety-one cases tabes appeared

within fifteen years after infection, in fifteen cases in the following five years, and in only six cases later than this. In a control examination of twelve hundred men over twenty-five years of age who had no symptoms either of tabes or of syphilis, he found 77.25 per cent. uninfected and 22.75 per cent. infected in early life. From this it follows, according to the author, that almost no one becomes tabetic who has not first been syphilitic. Of thirteen tabetic females, four were free from syphilis, in three it was doubtful, four had had positive secondary syphilitic symptoms, one probably syphilitic, and one a chancre. From the above Prof. Erb concludes that syphilis is one of the most frequent causes of tabes dorsalis, if not the most frequent.—*Centralb. f. d. Med. Wissen.*, December 15, 1883. S.

WOOD-WOOL AS A SURGICAL DRESSING.—Under this name Bruns recommends as a surgical dressing the fine fibrous scrapings obtained from wood-polishing factories. For surgical purposes the scrapings of white pine are the best. When in the fresh condition it contains from sixty-five to seventy-five per cent. of water, and it must, therefore, before use be pressed, powdered, and dried. As prepared by Hartmann, in Heidenheim, it is extremely soft, very porous, and fulfils all the requirements of a capital dressing for surgical cases. One of its great advantages is its immense power of imbibing fluids, it being able to absorb twelve times its weight of water, while the turf recommended by Neuber takes up only eight times its weight, and even then requires to be first moistened. It is, moreover, extremely cheap, fresh, absolutely clean, of a white color, and is indeed an ideal "dry dressing." It may also readily be impregnated with the different antiseptics: of these the sublimate is recommended, and is furnished by Hartmann containing one-half per cent. sublimate and five per cent. glycerin. This preparation is now exclusively used in the Tübingen Surgical Clinic, and is preferred by Bruns to carbolic acid or any other antiseptic.—*Centralb. f. d. Med. Wissen.*, December 15, 1883. S.

THE USES OF IODOFORM IN GENERAL SURGERY.—The report of the service of Prof. von Mosetig-Moorhof (*Bericht des k. k. Krankenhauses Wieden vom Solarjahr 1882*) shows that during the last five years

he has treated altogether seven thousand cases with iodoform, and he states that he can see no reason for giving up its use. He has sought in vain for toxic symptoms in any of his cases. He uses it as (1) a powder, *not* in crystals, sometimes employing (2) iodoform gauze (50 per cent.), and in the form of (3) an emulsion composed of from 5 to 25 parts of iodoform, 50 of glycerin, 10 of water, and 0.25 part of gum tragacanth. The latter is especially useful in punctured wounds and complicated fractures. In thirty-five such fractures there was only one which presented septicæmic symptoms. He also uses (4) iodoform crayons, and (5) iodoform solution for parenchymatous injections. The solution he uses is as follows: iodoform, 1.0; benzine, 9.0; paraffin (liquid), 10.0; oleum gaultheriæ, gtt. ij. This is especially serviceable in lymphadenitis and parenchymatous struma. Local tuberculous processes can be treated by this solution after all the diseased parts have been carefully removed. In a table of eighty capital operations treated by iodoform dressings remarkably good results are shown.—*Centralblatt für Chirurgie*, No. 48.

TREATMENT OF ERECTILE TUMORS IN CHILDREN.—After unsatisfactory experience in the treatment of erectile tumors in children by means of vaccination, thermocauterization, and cauterization with the Vienna paste, Dr. de Saint Germain recommends as the most satisfactory the injection of the tumors with Piazza's solution. This consists of chlorinated soda, fifteen parts, liquor ferri sesquichloridi (thirty per cent.), twenty parts, and water, sixty parts. Through this injection a coagulum of the blood in the tumor is produced, and the growth shrivels up. It is necessary to be careful that none of the injection enters the normal tissue, or violent inflammation will be produced. Occasionally, however, this method of treatment will fail: resource must then be had to some caustic paste, or to the antiseptic excision of the tumor.—*Centralb. für Chirurgie*, October 13, 1883.

TUBERCULOSIS OF THE VAULT OF THE PALATE.—Out of three hundred to four hundred cases of tuberculosis which come annually to Guttman's clinic, he finds that only one per cent. is affected by tuberculosis of the vault of the palate and

its adnexa. Lublinski has met with only ten cases out of a total of sixteen thousand patients seen in five years; although twenty per cent. of all of these were affected by disease of the air-passages, and it was always in those patients in whom the tuberculosis of the lungs and larynx was very far advanced that he saw this complication. Guttman states, in answer to the possible criticism that many cases may escape unnoticed, that this is scarcely possible, on account of the pain caused by the disease, and especially the difficulty in deglutition.

As to the etiology of the affection, these two authors endorse the opinion of Rindfleisch that tuberculosis of the larynx is occasioned by the expectoration, and in like manner is the vault of the palate affected. As a primitive disorder the disease does not exist.—*Deutsche Med. Zeitung*, No. 19, and *Revue Mensuelle de Laryngologie, d'Otologie et de Rhinologie*, December.

THE MICROBE OF HYDROPHOBIA.—At the Academy of Medicine (November 27) Pasteur referred to his discovery, in the saliva of a child who had died of hydrophobia, of a microbe susceptible of cultivation and of inoculation in guinea-pigs, causing their death, and stated that after culture-experiments it could be introduced into rabbits without fatal results. The experience of Pasteur has shown in regard to microbes in general that a disease-virus is not a morbid entity, and although virulence belongs as a property to some species of micro-organisms, it is modifiable essentially: it can be increased, it can be reduced, and each of these states is capable of fixation by culture. He stated that microbes which are virulent in one animal may be harmless in another, and the virulence of the poison may be very much modified by its passage through several animals of the same species.—*La France Médicale*, No. 64.

LOCAL TREATMENT OF ERYSIPELAS.—An epidemic of fifty cases of erysipelas gave Polyányi an opportunity of making comparative observations of different methods of treatment. The best results were given by applications of freshly-prepared sulphurous-acid solution, made carefully every two hours over every part of the affected surface. J. Andeer prefers a fifty to eighty per cent. ointment of resorcin.—*Wiener Med. Presse*, Nos. 22 and 23.

EDITORIAL.

REMARKS UPON MEDICAL EXPERT TESTIMONY SUGGESTED BY THE DWIGHT CASE.

THE prominence which has been given to medico-legal questions in the recent case of Colonel H. J. Dwight, of Binghamton, warrant a reference to it here in order to emphasize a few remarks upon medical experts and the character of expert testimony. An extended history of the case will not be required by our readers, who are familiar with the details as they have appeared in the public prints: stated in its briefest form, it was that of a man who as a result of large speculations had become a bankrupt, and who, while supporting his family extravagantly upon borrowed money, had made application to nearly every life-insurance company in the United States for insurance upon his life, and, in fact, had actually obtained policies aggregating nearly four hundred thousand dollars, upon which he had paid the first quarterly premium with money borrowed for the purpose. As he was without income, it happened very opportunely that he died rather suddenly on November 15, at a time when he was alone in his room. The death, indeed, was timely, because he had just been successful in passing through bankruptcy, and also because in a few days the second quarterly instalment would be payable, which he had no funds to meet, and failure would involve forfeiture of the money which he had already paid. The insurance companies contested the claim on account of fraud, on the ground that Colonel Dwight had committed suicide; but it was also in evidence that his replies to some of the

questions in his application for the policies were false and misleading. The original theory of the plaintiffs was that the man had killed himself with gelsemium; but the experts were agreed in attributing death to strangulation with a cord, marks of which were plainly demonstrable both at the first post-mortem and at the second, performed four months later. The dissenting testimony (as we gather from a critical review of the case by Dr. H. C. Wood in the *Medical News*) was confined practically to Drs. Hyde, Burr, Chittenden, and Orton, Mr. Ayres, the undertaker, and two other non-medical gentlemen, who believed the creases in the neck to have been caused by forcibly flexing the head after death, when placing the body in the ice-box. None of these medical gentlemen, however, who were called upon the part of the plaintiffs (*i.e.*, executors of Mr. Dwight), ventured to assign a natural cause for the death, or to deny the alleged strangulation. Dr. Swinburne, who made the autopsy, Drs. Porter, Bridges, and Sherman, and the experts called in by the insurance company to investigate the theory of supposed poisoning,—Dr. Austin Flint, Jr., of New York, and Drs. Roberts Bartholow, Theodore G. Wormley, Isaac Ott, and H. C. Wood,—were unanimous in the conclusion that death had been due to strangulation, probably by the patient hanging himself to the bed-post. Notwithstanding the able and positive medical testimony, the verdict was given against the life-insurance companies, who have since appealed the case in the interests of public morality and as a measure of protection to the funds belonging to the other policy-holders, of which they are the trustees.

It was peculiarly unfortunate that, before the case had been finally decided, an editorial attack should have been made upon the expert testimony in the *Medical News* (December 22), which claims that the view held by the experts at the trial was erroneous, and that death was caused by the

combined effects of disease and large doses of morphia administered by the attending physician, Dr. Burr. The death by asphyxia was not denied, nor that "he suddenly and without premonition sunk away and died;" but death is attributed to the effects of morphia, in the face of the facts that he had been doing well and talking rationally—according to the testimony of Mr. Hull, who sat up with him—up to within a few moments of his death, and that his heart-tissue was pronounced healthy in the report to the court.

It would be very unusual, to say the least, to find a *hypodermic injection* of morphia, given not later than half-past nine in the evening, exercising suddenly, two hours later, a fatal paralyzing action upon the respiration and heart, without being preceded by any evidences of narcosis or other of the classical symptoms of morphia-poisoning, which are so easily recognized. Moreover, there was no evidence to show that the hypodermic injection was in excessive dose.

We pass without comment the reflection which the editorial alluded to casts upon the character of the attending physician, who, according to this view, made himself *particeps criminis* by contributory negligence, if not by design, as this reflection may lead to legal proceedings which will still further elucidate the peculiar etiquette of expert practice in this country.

We take this occasion to affirm our convictions that medical men who are summoned as experts do not thereby relinquish their right of independent judgment, or their freedom in declaring their views in court upon the questions submitted for their consideration by either side: due respect to themselves, and to the medical profession which they represent, should restrain them, therefore, from allowing themselves to be placed in the attitude of partisans. In declaring "the truth, the whole truth, and nothing but the truth," they are aiding the cause of justice: no obligation

should be assumed that would commit them to any other course or oblige them to do less than their duty. Again, experts are selected as especially qualified to decide upon certain difficult medical questions coming up for consideration in the course of the case. Does it not seem inconsistent with this view, as well as undignified, for eminent men, who differ in their views, to appeal to the profession at large, or seek a rehearing of the case at the bar of public opinion? The world has not yet recovered from its disgust at the character of the testimony and behavior of the medical experts at the Guiteau trial, in which scenes occurred that have reflected lasting discredit upon American medicine. The public will begin to have more respect for the medical profession when the leading members of the profession show more respect for themselves.

REMARKABLE RESTORATION OF VISION FROM INJURIES TO THE HEAD.

THE case of Mr. Maybee, of Long Island, has attracted considerable attention and has led to some discussion. The patient had been a sufferer with spinal disease for fourteen years, and became totally blind about a year ago. He was an invalid, and advanced in years. While sitting in his chair one afternoon last November, he was beaten about the head by burglars, who also murdered his wife and daughter. He was naturally under great excitement at the time, and lost considerable blood from scalp-wounds. Strange to say, a few days later he commenced to recover his sight, until he could distinguish different individuals, although vision was not quite clear. His general condition was fair, and his pulse good.

The opinion of Dr. Knapp, as published in the *New York Herald*, is that the patient might have had advanced cataract, and that, the fastenings of the cataractous

lens becoming broken up by the blows upon the head, his vision was partially restored. The newspaper suggestion that the injuries had any effect upon the optic nerve is rejected as untenable.

That loss of vision, with the appearances of atrophy of the optic nerve, may be due to sudden fright or shock, is generally known. Central scotoma likewise may be developed from inanition during an enfeebling general illness, and also from the use of tobacco. Now, since these conditions have been relieved by various methods of treatment, and in some cases vision has been restored quite unaccountably, we should not reject too positively the hypothesis of the combined influence of concussion, local hemorrhage, and cerebral excitement in restoring vision in the case under consideration.

It is true that advanced spinal disease is apt to be accompanied by optic neuritis; but, in the absence of a record of the case previous to the injury, it cannot be said positively whether the eye-symptoms were complications of the spinal affection or existed independently of it. Before denying that any given agent can be useful in benefiting optic atrophy, it would be well to try and explain why strychnia is sometimes of such signal value. Dr. David Webster, of New York, in a communication to *The Planet*, reports a case of this kind in a stable-man who was so blind that he had to be led to the hospital, but who, under the use of strychnia hypodermically, recovered the sight of both eyes so as to be able to read fine print, the appearances of atrophy of the optic nerve being retained, although sight was restored. Other cases are reported cured by electricity and by electro-magnetism.

Dr. Webster stated that the blows upon the head of Mr. Maybee must have powerfully affected his nervous system, and to this shock and to the sudden intracranial changes induced by his great fright and mental excitement, in his opinion, may be

attributed the change in the nutrition and conducting power of his optic nerves, and the partial restoration of sight.

DISASTROUS CONSEQUENCES OF NERVE-STRETCHING.

THE dangers of the purely empirical treatment of obscure nervous disorder by the process known as nerve-stretching have been pointed out recently by several observers with sufficient emphasis to lead to caution in the practice of a method which has no scientific basis, often fails to relieve, not infrequently inflicts injury upon the patient, and may even be followed by fatal results.

Westphal reports* the case of a man, aged 31 years, who suffered from a slowly-progressive loss of power of the lower extremities, associated with spastic phenomena, involuntary contractions, increased reflex irritability, exaggerated knee-reflex, and disturbances of sensation. This last symptom was particularly marked as regards the perception of differences of temperature. It extended over the legs and body, and varied at different times. After vigorous stretching of the right crural nerve, the muscular stiffness and knee-reflex disappeared, the latter temporarily, while incontinence of urine and fæces, contraction, and bed-sores were added to the other symptoms. These symptoms gradually increased in severity, and, after an intercurrent right-sided hemi-anæsthesia and ataxia, death occurred three years after the operation. On post-mortem examination, circumscribed points of degeneration were found in the brain, pons, and medulla oblongata, with diffuse softening of the cerebral and dorsal portions of the spinal cord (most marked in the middle dorsal region), with multiple points of degeneration in the right half of the lumbar cord. The process, therefore, was one of chronic circumscribed cerebral degeneration.

* Centralb. f. d. Med. Wissen., December 1, 1883.

tion, associated with diffuse spinal degeneration; and the author believes that the disease in the right half of the lumbar cord was without doubt a consequence of the stretching of the crural nerve.

The author also reports a case of spastic spinal paralysis, in which nerve-stretching produced a temporary improvement in some of the spastic phenomena, without, however, resulting in any perceptible permanent benefit.

LEADING ARTICLES.

THE NORTHWEST AS A HEALTH-RESORT.

IN Dr. Wood's article on "The Southwest as a Health-Resort" are presented claims that are equally shared by some sections of the Northwest, notably Montana. It is within the dry belt of the Rocky Mountain regions, and in this particular has possibly the same influence that Texas has, being quite as dry, and moderately elevated. There are here two seasons wherein are frequent rains, one of four to six weeks in late spring, and another of one to two weeks in fall, corresponding to the equinox of the Eastern States. Infrequent showers occur during the year, and snows during the winters, though often a whole season passes without enough to make sleighing; this, of course, in the less elevated sections, for on some high plains and on the mountain-ranges are deep snows throughout the winter. This section of the country is, strictly speaking, a desert land, as defined by the statist, where the farmers must irrigate to raise crops,—a land where dew never falls, where one can lie or sleep on the ground without taking cold, and where dust follows the traveller at all seasons alike.

The amount of rain-fall, as registered in the Helena signal-office for 1882, is 6.8 inches, which includes the melted snow.

The dryness of the atmosphere here is appreciable in every-day life. The dead bodies of small animals, such as cats, dry up with little or no inconvenience attending disintegration. Before our town was incorporated, their carcasses were never carted away, and in alleys and dark places they were often a stumbling-block. The

hunter, resting beneath a tree, may hear the creaking joint of the Sioux Indian—the *good Indian*—resting on the branches above, but no tainted atmosphere directs his attention to the mausoleum. Indeed, it seems to be a country where one may dry up and blow away.

The average altitude of Montana is three thousand feet, while that of Colorado is seven thousand, of Wyoming six thousand, of New Mexico five thousand six hundred. This slight elevation, with the warm western winds of the Japan current, gives us a comparatively mild climate. "The isothermal line of 50° F., passing through Harrisburg, Cleveland, and Chicago, runs from southwest to northeast through the Territory. Our mean temperature is that of Pennsylvania and Central Ohio."

There are severe and sudden changes; but can we say less of Texas? Are we sure these changes are deleterious to health? I have heard visitors to Lower California complain that the regular, even temperature there was tiresome and monotonous and caused one to grow languid and dull.

Professor Wood compares Texas and Colorado, and justly pronounces in favor of Texas. The elevation of Colorado is too great. The result is, cold severe winter; but a more serious effect is that the great high spurs and peaks of its mountains are continuously covered with snow, and during the summer sunshine this snow melting loads the atmosphere with moisture, the evaporation creates such conditions that regular daily breezes sweep down over the plains, and the population is injured rather than benefited. Established lung-irritation is increased, and nasal catarrh is made common. Montana is free from this condition, and allows nothing in favor of Texas. Nor is the difference in elevation less in our favor. Coming from the sea-level, one finds his lung-capacity a little wanting in our rarefied atmosphere, but in time his lungs grow up to the requirement and no extra work is called for. The travelling clothier tells me the chest-measure of the old-timer is very positively above that of the man in the States, and percussion over the heart's area reveals so much covering of lung-tissue as to make the usual dulness almost wanting. So striking is this to the pilgrim doctor that he hesitates to accept such order of things.

In cases that have a loss of lung-tissue so

great as to reduce the supply of necessary oxygen, it is questionable if benefit is afforded by coming to an elevated region. Some sudden deaths attend such patients coming here; yet we have witnessed some such remarkable recoveries as to make us slow to discriminate. As to a special proneness to hemorrhage, it is purely theoretical, for it does not exist. In no branch of practice or disease is hemorrhage more common in our town than in the States. I was taught, and saw demonstrated by apparatus, that patients with emphysema of the lungs wanted condensed air: up here in our rarefied, sparse air we seldom meet the disease, while asthma invariably deserts the patient on the route.

In the cases of inherited consumption the positive lung-growth acquired in our elevation is one of the special favors bestowed. The numerous cases that life on the plains has cured are due more to the increased lung-expansion and final growth than to simple exercise and fresh air.

It seems established as a fact that dry air or a dry climate is favorable for lung-diseases. It is likewise assumed that a warm climate is better than a cold one. This is not proved. Do not consumptives complain of hot weather, of languor and debility? Do not consumptives who reside in and about Philadelphia die most commonly close on an exhaustive summer at "the falling of the leaves"? Does real cold weather produce any ill results, or are the patients any worse during such terms? Our mortality list shows, for the three past years, one consumptive death for January and December to four deaths for August and July. Can Dr. Wood on theoretical or practical grounds advise that the comfortable winter weather and hot summer weather of Texas are better than the cool comfortable summer and the cold winter of Montana? In the mortality report of Helena, of six thousand inhabitants, for 1882, I find that during July, August, and September there were two deaths from all causes; none of children or from disease due to heat.

January and February had, respectively, twenty-four and twenty clear or fair days, such as invalids could exercise in: our roads being almost always dry, they can go out at all times. If it is not an established fact that warm dry air is better for consumptives than cold dry air, I should like to invite the attention of the profession to the North-

west as a health-resort offering more inducements than the Southwest. I do not include in this Minnesota or any of the Northwestern States,—there they have a moist atmosphere, and severe storms and winters,—but limit my call to Montana. We have only in part the diseases of the States, and with many modifications; no malaria, no asthma, little or no summer complaint; while we have hot springs for hygienic use, hunting for amusement, and mining, farming, and cattle-raising for employment. A *Helena Herald* item, of some numbers back, reads thus: "Dr. Blake returned from a nine days' hunt with twenty-two deer and one grizzly bear." In the suburbs of Helena is a hot spring of unlimited capacity at a temperature of 150° F., and identical with the Arkansas Hot Springs in chemical analysis; thirteen miles distant is a similar spring; forty miles is a famous hot spring; sixty miles is a hot sulphur spring; and thus throughout the Territory.

The Board of Health furnishes for Helena, Montana, from October, 1880, to April, 1883 (two and a half years), the following: Population, six thousand; number of deaths from all causes, one hundred and seventy-four; number of deaths from consumption, thirteen; mean age of deaths from consumption, forty-one years.

We are not entirely free from the disease, but the actual death-rate, I am sure, is less than the table. One case given was death from old age and intemperance, another was strictly syphilitic, one from strangulation due to an abscess of the lungs, one, tubercular laryngitis. One of our physicians died upon whom judgment was pronounced twelve years ago by eminent London physicians. Experience confirms a long-formed opinion that Montana Territory offers more inducements as a resort or home for consumptives than any other section. Our geographical position needs much allowance. One of our dailies, speaking of the severe snow-storms four weeks ago in Colorado, says, "Such a sad state of affairs has never existed in Montana, and there is no country, probably, in the world where the people are so free from the visitations of storm and flood, and where there is such exemption from the casualties incident to extremes of heat and cold." At this writing, December 15, the thermometer registers 25° F., and

it is one of a continuous succession of clear, sunshiny days from the 1st. Unless the winter prove to be an exceptional one, we shall have this same sunshine, clear, bright, calm days, and smooth, dusty roads, on through this month, and the next, and the next.

J. J. LEISER, M.D.

HELENA, MONTANA, December 15, 1883.

NOTES FROM SPECIAL CORRESPONDENTS.

NEW YORK.

GRAVE CHARGE AGAINST A MEDICAL COLLEGE.

SINCE the passage of the new law, the County Medical Society, through its Board of Censors, has undertaken the work of prosecuting persons illegally practising—or, rather, pretending to practise—medicine. E. C. Ripley, Esq., attorney for the Board of Censors, states in his annual report,—

"Thus it will be seen, by an examination of my report for last year and the present report, that this New York Eclectic College, within the last two years, notwithstanding the widely-published prosecutions of these men, their well-known characters, and the disgusting advertisements of some of them, has 'graduated' John Wesley Grindle, E. B. Light-hill, James Bryan, Adam Claesson, and William H. Fuller, and solemnly declared them to be fit men to practise medicine. It should be the first duty of every reputable physician to make known this shameful state of facts, and join your Board in bringing to justice men who have been engaged in this unprofessional and disgraceful affair." "This man Bryan is one of the most notorious quacks in this city. He has been connected with numberless swindles, and published far and wide in the public journals, and occupies a prominent chapter in Anthony Comstock's book 'Frauds Exposed.' His arrest by us was published in the city papers; yet, in the face of these facts, and while he was under indictment awaiting trial, he registered as *another* of the 'graduates' of the New York Eclectic Medical College."

We understand that the Board has since taken steps to have the charter of this college rescinded, on the ground of having illegally granted diplomas. In evidence of the good work done by the Board, Mr. Ripley says, —

"My observation prompts the remark that in no class of cases in the criminal courts is there as large a percentage of convictions as in the cases prosecuted by your Board; and the Board may well feel proud of this, another year's successful work, evidenced not alone by this report, but by the generous and merited support of the public press, and favorable public sentiment generally."

SANITATION.

The hands of politics seem again to have been laid upon the Board of Health, the result of which will probably be decreased efficiency in sanitary inspection. With the numerous shell-like buildings which are going up with almost lightning rapidity, certainly this is not desirable. It would not be difficult for Prof. Doremus to find plenty of walls here at the present time which would permit of the easy penetration of gases. Although the temperature very seldom goes down to zero, yet in the large majority of dwellings, especially those recently constructed, the occupants feel themselves obliged to allow the water to run from every faucet during the night, and often during the day, as a safeguard against freezing. If by accident this is neglected, the next day the plumber must be called to repair bursted pipes. No wonder, therefore, the need of greater water-supply. But, with the facilities which New York has for getting water, it might just as well as not have its streets constantly flooded, if necessary. As it is, the people who live above the second floor await the new Croton aqueduct with impatience.

DISPENSING DRUGGISTS.

Your recent editorial suggests that some steps might well be taken by the physicians of this city also towards checking the spread of life-destroying patent drugs, and that form of irregular medical practice cloaked under the uncertain terms "druggist," "apothecary," "pharmacist." On the avenues in this city one frequently sees as many as from two to three drug-stores in walking a single block. Some of them are limited to a room of about ten by twenty feet, are situated in the middle of a block for want of means to pay corner-rents, and perhaps have inscribed in golden letters on the windows the significant term "Smith's Dispensary," or its equivalent, and here ignorant people, and even some of the well-to-do financially, go for medicine that will relieve a cough, rheumatism, pain in the side, venereal trouble, etc., receiving the "doctor's" advice free, and paying anywhere from ten to seventy-five cents for the drug. These benefactors of the afflicted portion of humanity often sell a concoction said to be of their own patent, now that a revenue stamp is not required on such packages. If a patient happen to come in with a reputable physician's prescription for a bronchitis, they noise it far and wide among their customers, and put it up for every one who comes in with a similar affection. Even the better class of pharmacists repeat physicians' prescriptions without authority, and devote one-half the shop to innumerable patent medicines.

R. C. S.

January 10, 1884.

PATERSON, NEW JERSEY.

THIS city has become what it is mainly through geological changes in its site in ancient times. The formation of red sandstone bears upon its surface very considerable mounds and banks of sand, the remains of ancient shores which have been greatly wasted by glacial action. Along its western side the sandstone is overlaid by a heavy body of trap-rock, resulting from intense volcanic action. This is named "first mountain," as it is the first occurring from seaward, and extends far away in a pretty direct line through the counties of Essex and Union, to the heart of Somerset. Hither from the adjacent table-land of Morris County comes the feeble stream that forms the head-waters of the Passaic River, which, keeping within this range of trap, skirts it in a northerly direction, until, at a point some miles west of Paterson, it turns directly eastward, finding its way through this rocky barrier at a remarkable rift, down which it plunges a depth of seventy feet. The walls and columns of trap which form this singular chasm, into which the water falls with wondrous power, constitute a most picturesque scene. The river then sweeps away with a rapid current eastwardly, the city rising upon both its banks. At the falls, a low dam having been thrown across the river just above, are situated the city water-works. The water is forced by steam-power to a reservoir upon an adjacent hill, very much as at Fairmount in Philadelphia. At this point, also, is placed a viaduct, which furnishes water-power to certain mills and carries water for the boilers of the great locomotive-works which are near by.

The older portions of the city are meanly built, the main object, apparently, being to secure the largest amount of returns from the smallest outlay. Many tenement-houses have been constructed during the past year on this selfish principle, the result being dwellings deficient in light, ventilation, and the means of privacy and the decencies of life. The easterly part of this city is building up in a style altogether different. Here are rising palatial houses, the abodes of the rich manufacturers and wealthy artisans, who are lavishing large sums on the construction of their homes. The inhabitants represent nearly every nationality on the face of the earth,—the French, German, English, and Irish constituting the larger portion. Its character as a manufacturing city is seen at a glance when the great manufactories pour out their living tides upon the public streets,—jostling hordes, carrying in their countenances and rude behavior the stamp of low mentality which constant manual labor, unrelieved by culture, inevitably brings.

Perhaps no city of its size in the United States is so destitute of literature and reading as this one. There is no public library of

any description worthy the name. The only attempt in that direction is a motley collection of old books,—perhaps one hundred in all,—open once a week in the evening, in the basement of one of the churches. The opportunities for mutual or individual improvement to physicians are most meagre. The County Medical Society, while having upon its rolls upwards of forty names, cannot usually muster over a half-dozen members at a regular monthly meeting; and the details are uniformly uninteresting and unprofitable, consisting chiefly of routine business. All the sociability to speak of in the profession finds expression in an annual dinner at the leading hotel. The prevailing idea in the minds of most of the members appears to be business. This dominates all else. The facilities for the succor of the homeless sick and maimed consist of two general hospitals, and one infirmary for diseases of the eye and ear. The former two have been in existence about ten years, the last about one year. The St. Joseph's, or, as it is familiarly termed, "The Sisters' Hospital," was originated and is supported by a sisterhood of nuns, assisted by the Roman Catholic clergy and people. It is well located, and is large, airy, and clean. It has a staff of physicians and surgeons who attend alternately at such hours as are convenient to them. Only within the last year has it maintained a resident physician. The "Ladies' Hospital" was founded and is supported by voluntary contributions, the leading ladies of the town soliciting and raising funds for its support. It has an elevated position, with interesting views, and is kept in admirable order. The medical attendance is of the same character as that of the first-mentioned, a resident having been recently appointed. Unfortunately, at neither of the hospitals could I learn that there was any systematic record taken of the patients, the history of their diseases, or the methods and progress of the treatment. There are separate wards for medical and surgical cases of each sex, and separate rooms for scarlet-fever patients; but such diseases as erysipelas, diphtheria, and consumption are treated in the general wards. So far as I can learn, there are no books of reference in either institution,—the only medical literature available being a few text-books belonging to the residents, and a few copies of medical journals. Of the practice in the two hospitals, that of the Ladies', where I witnessed some good surgery, seemed the better. A colotomy and a cataract extraction—the last from the Eye Infirmary, which has a bed here—were skilfully performed. I was not present at any of the practice of the Sisters' Hospital, but close inquiry satisfied me that there was lack of system and thoroughness in the manner of investigating diseases, and a singularly ancient and unsatisfactory style of therapeutics.

In the line of sanitation the city has a Board of Health and an Inspector of Provisions, who are earnestly working for the preservation of the public health. They find abundant opportunity for the exercise of the functions of their office, in correcting the habits and practices of the filthy, the selfish, and the ignorant.

E. T. BLACKWELL.

CORRESPONDENCE.

HOMICIDE SECUNDUM ARTEM.

EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR DOCTOR,—I have read with much interest your editorial in the *Philadelphia Medical Times* for December 1, on "Homicide secundum Artem."

A few years ago, it happened in a New-England town that a physician attending a case of labor where a monstrosity was brought forth decided that the miserable child was unfit to live, and, after cutting the cord, having purposely omitted to tie either end, he allowed the child to bleed to death in his presence.

The case was reported at a meeting of the Medical Society to which this *executioner* belonged. One or two were in favor of taking active measures against such a high-handed and very unprofessional proceeding, but were somewhat held in check by reason of the opposition of a prominent member, who, if not very highly respected, was certainly much to be feared. I remember that I took the occasion to denounce such conduct not only as unprofessional but as actually criminal. You can understand that very few sympathized with me, when I tell you that upon a friend of this physician making a very slight apology for this proceeding, and extending an invitation for the Society to hold its next meeting in the town where he resided, *and to accept his hospitality and dine with him, the invitation was accepted.* A few, the writer among the number, felt that they could not, with any respect for the profession, accept the invitation under the circumstances, and stayed away. The enterprising host, however, was rewarded by being elected President of the Society. I felt somewhat severely punished for my meddling, and vowed that I would try to be more guarded in future. Is it not unworthy of the honorable profession of medicine, upon whose banners is inscribed the motto, "Our duty is to save, and not to kill," that there should be any doubt as to our procedure in such cases? We are responsible to the patient, to his friends, and to God for the most faithful performance of duty possible; and never should we consider ourselves placed in a position to exercise our judgment in opposition to his will.

In case a monstrosity is born, we are in duty bound to proceed by regular obstetrical usages, if not laws, to sustain life, trusting in God, "*to whom alone belong the issues of life and death.*" If our noble profession is to be degraded to the level of a trade, then, perhaps, we shall find men belonging to it in doubt as to whether we are sent to take life or to endeavor to save it. Thanking you for your valuable editorial, I am very truly yours,
A MEMBER OF THE MEDICAL PROFESSION.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

AT a meeting held December 12, 1883, Dr. W. M. Welch, President, in the chair, Dr. Arthur V. Meigs read a paper entitled "Proof that Human Milk contains only about one per cent. of Casein: with Remarks upon Infant-Feeding."

In this communication the lecturer demonstrated, by the process of exclusion, from a series of analyses, that human milk does not contain more than about one per cent. of casein, as an average. He made the following practical remarks, in conclusion, upon "infant-feeding," and recommended the following method of preparing the food:

"The easiest way to prepare and use the food is as follows. There must be obtained from a reliable druggist packages of pure milk-sugar containing seventeen and three-quarter drachms each. The contents of one package are to be dissolved in a pint of hot water, and it is best to have a bottle which will contain just one pint, as there is then no need for further measuring. The contents of one of the sugar packages are put into the bottle, and when filled with hot water the sugar soon dissolves and it is ready for use. The dry sugar keeps indefinitely, but after it is once dissolved it sours if kept more than a day or two in warm weather: it is understood, therefore, that the sugar-water must be kept in a cool place, and if it should at any time become sour, as is easily discovered if it is smelled and tasted, it should be thrown out, and, after the bottle has been carefully washed with boiling water, the contents of a fresh package dissolved. A milkman must be found who will serve every day fresh, good milk and cream. By good milk is meant ordinary milk, such as is easily procured in most cities, and not rich Jersey milk; and in the same way the cream should be such as is ordinarily used in tea and coffee, and not the very rich cream of fancy cattle. The reason that ordinary milk and cream are recommended is because they are within the reach of almost every one, and not because they are any better than the rich milk of high-bred stock.

If Jersey milk were to be used, it would be necessary to analyze specimens and then make the necessary calculations as to how to dilute it to obtain the desired relative proportions of the proximate principles. When the child is to be fed, the nurse should mix together two tablespoonfuls of cream, one of milk, two of lime-water, and three of the sugar-water, and then as soon as the mixture has been warmed it may be poured into the bottle and the food is ready for use. If the infant be healthy, this quantity will not satisfy it after the first few weeks, and then double the quantity must be prepared for each feeding. Twice as many tablespoonfuls of each of the ingredients must be mixed together, making sixteen tablespoonfuls (about half a pint) in all.

"This food should not be given any stronger until the child is eight or nine months old, at least; but if the infant be a healthy one, it may take as much of it as it wants, but always of the same strength. A robust infant will often take three pints, or even more, in each twenty-four hours. It is an easy matter for any one to learn how to make the lime-water; and it is advisable to have it made at home, for a great deal is used, and if it is made at home much trouble and expense are saved.

"With regard to the propriety of increasing, from week to week, the strength of any artificial food given to infants there has been some question. Most authorities have advised that the foods should be increased in concentration until finally the infant is given pure cow's milk. The propriety of this procedure, during the earlier months of life at any rate, is very doubtful. Although there is some reason to believe that the quantity of solid ingredients in human milk increases from month to month as lactation goes on, such an opinion should be accepted only with great caution, for it seems likely that if there is any increase in the concentration of the milk after the colostrum has once disappeared and the nursing process has settled down into its even course, the increase is so slight that it may be disregarded. Analyses show that the milk of a woman whose child is two months old does not differ materially from that of one whose child is twelve or fifteen months old. If, then, nature has made no difference which our means of analysis will detect between the milk of a woman who has been nursing two months and one who has nursed twelve, an artificial food which has been found to suit an infant of two months should be made more concentrated only very gradually, and with careful observation of the effect upon the health of the infant. It is best, therefore, if the infant thrive and grow as it should, not to make any change in the food until after six to nine months of age have been attained.

"With regard to the use of condensed milk as a food for young infants, I can only repeat what I said in my former paper,—that

I cannot believe that any article which has been canned, and kept for weeks or months, or perhaps still longer, can be as good as the same thing when fresh. My table of analyses shows the composition of the dilution of condensed milk commonly used in this city, and it shows that the proportion of fat is much too small, and for this reason, partly at least, it fails as a food. Its success is due to the fact that it contains nearly the same proportions of casein and sugar as exist in human milk. Dr. Ellwood Wilson is in the habit of directing that after the first few weeks a small proportion of fresh cream be added to the condensed milk, and this would render it still more nearly what is needed. This practice, which cannot be too much commended, if condensed milk be used, is not, however, at all a common one. Withal, I am unable to believe that condensed can be as good as fresh milk, if properly used."

At a meeting held December 19, 1883, Dr. Roberts Bartholow read a paper on "Nitro-Glycerin and the Chloride of Gold and Sodium in the Treatment of Albuminuria." The former remedy (in one per cent. solution) is recommended, in drop doses, in the more acute cases, influencing as it does more directly the blood-supply; the other, a double salt, is indicated in the subacute and chronic cases, especially the latter, in doses of one-tenth of a grain at first, reduced at the end of a week to one-fifteenth of a grain, then continued for a month in smaller doses. If good effects are not observed in two weeks, they may be discontinued. He had observed very good results from its use in this class of cases.

Dr. Charles H. Burnett read a paper on "The Supposed Connection between Ear-Disease and Kidney-Disease," in which, after reviewing the testimony of different observers, he arrived at these conclusions:

1. Evidences in favor of either frequent or well-marked aural lesions dependent upon renal diseases are extremely meagre.

2. Those lesions in the ear which have been found in connection with Bright's disease and diabetes mellitus, and which may have been dependent upon the dyscrasia induced by these renal disorders, are in the form of sero-sanguinolent and hemorrhagic effusions into the drum-cavity. But the latter must not be mistaken for the sthenic form of otitis media hæmorrhagica.

3. From the serous nature of the membranous structures of the labyrinth, organic changes might reasonably be expected in Bright's disease; but positive proof of the occurrence of such lesions based on ante- and post-mortem history is wanting.

Dr. James Tyson read a "Note on Some Recently-Suggested Delicate Tests for Albumen." In this communication he con-

sidered—1, a saturated solution of picric acid, suggested by Dr. George Johnson; 2, saturated solution of ferrocyanide of potassium after free acidulation by citric acid, suggested by Dr. Pavy; 3, standard solution of potassio-mercuric iodide, suggested by Tanret,* after acidifying the urine by citric acid; 4, equal parts of a saturated solution of sodium tungstate (1 in 4), saturated solution of citric acid (10 in 6), and of water; 5, acidified solution of potassio-mercuric iodo-cyanide. The last two were suggested by Dr. George Oliver in the *Lancet*, February 3, 1883. To complete our list of available tests, he added—6, the ordinary heat and acid test; 7, the nitric acid test, by Heller's overlaying method; and, 8, the acidulated brine, suggested by Dr. Roberts, of Manchester, England, and consisting of an ounce of hydrochloric acid added to a pint of water saturated with common salt, and filtered.

The lecturer, after reporting the result of his experiments, concluded that the sodium tungstate solution and the ferrocyanide of potassium, but particularly the former, are more delicate, as tests for albumen in the urine, than heat, acid, or brine. These tests, however, like picric acid, precipitate peptones as well as albumen, and this may be a possible source of error. The ferrocyanide does not precipitate peptones, but gives a deposit with amorphous urates. If the quinine fallacy of the picric acid test be borne in mind, this solution, acidulated with citric acid, is an available test of great delicacy, cheap, and easily prepared; but the sodium tungstate was preferred, as being less liable to cause error. He would not, however, dispense entirely with the old heat and acid test.

Dr. William S. Little read a paper entitled "Eye-Symptoms and Conditions in Bright's Disease." He stated that among nine hundred and eleven cases of Bright's disease reported by different observers changes in the retina had been recorded in one hundred and eighty-five, or about twenty per cent. Amaurosis had been known as a symptom of dropsy even before the renal disease was recognized by Bright, and long before the use of the ophthalmoscope. He continued as follows:

"Retinitis, generally symmetrical, if not always so, appears in all forms of kidney-disease, while it is principally associated with the chronic disease of the cirrhotic kidney. Even though symmetrical, its presence is not always known to the patient. Especially is this so as long as the region of the macula lutea in the retina is not affected so as to produce a central scotoma. Lesions near the nerve and peripheral parts of the retina are not so pro-

ductive of recognizable scotoma in the field of vision. These cases do not have the restricted visual field and rarely the loss of color-sense that belong to optic nerve and brain troubles or contracted field of glaucoma. The symptoms may correspond to those of retinitis from any other cause,—flashes of light, color-sensations, dread of light, impaired vision, to total blindness.

"The ophthalmoscopic examination may only reveal the lesion, the patient being ignorant of it and not observing the gradual change. The picture of this form of retinitis is a decided one, as a rule. When the changes are slight, it is uniform, though at times a differential diagnosis is required from the conditions of the optic nerve and retina due to intracranial disease or to pernicious anæmia.

"While the lesions occur generally near the optic nerve and to the temporal side, the nerve itself is not implicated to the degree that might be expected from the picture it presents. The separate spots in the retina finally coalesce, approaching the disk and involving it; in other cases they surround the region of the fovea centralis and are much smaller. They may occur anywhere in the retina, varying in size; the shape is somewhat quadrilateral, but may vary as they progress; they present a white appearance. The tissue near the disk, and the disk itself, appear striated; spots of hemorrhage are found from rupture of retinal or choroidal vessels; opacities in the vitreous are seen. The state of pigmentation is the latest. In chronic cases the color of the fundus is peculiarly yellow, and the character of the picture is at times very much like the neuro-retinitis of brain-disease or pernicious anæmia.

"The changes result from the hyperæmia and infiltration of the tissue, fatty degeneration and atrophy producing changes in the blood-vessels with hemorrhage; a fatty deposit occurs in the retinal tissue, the fibres of the retina become sclerosed, and pigmentation follows.

"The optic nerve is not seriously involved, though gray degeneration may exist and numerous amyloid bodies may be seen with the microscope. The retina does not always present all the stages described; the kidney-disease being amenable to treatment, the retina may not undergo any further change; where it is chronic, a like progression ensues in the retina. Marked lesions at times disappear, leaving only a slight trace. The hemorrhagic state is more severe, the sight not only being lost, but the patient's life also being endangered.

"During gestation the same picture exists; the optic nerve may be more seriously involved. A case recently seen, and having uræmic symptoms, being unconscious two weeks prior to the delivery of the child, it being born dead, had complete atrophy of one optic nerve, with extensive retinal lesions;

* Mercuric chloride, 2.7 grains; potassium iodide, 6.4 grains; distilled water, 100 c.c.

the other nerve partially affected, and slight retinal changes; patient almost entirely blind. In another case, with convulsions, only slight changes in each eye near the fovea. In succeeding pregnancies the conditions may arise again, producing more serious changes in the retina.

"The prognosis, so far as the vision is concerned, is serious when the region of the yellow spot is encroached upon; and yet fair vision may remain after subsidence of the disease.

"Can a prognosis as to the duration of the disease or as to its fatality be derived from the eye-symptoms? Only in the chronic stages of the disease, when retinal hemorrhages are extensive and repeated, the heart being diseased. Traube considered the heart the immediate cause of these retinal hemorrhages, but they exist in cases without heart-trouble and in other diseases of the system, and in intraocular conditions. Brain-symptoms soon follow in these severe types of retinitis, in chronic kidney-disease a general hemorrhagic condition being developed, or uræmia may ensue. In the acute forms of Bright's disease no prognosis of any value can be formed from the eye-symptoms, though severe.

"As to treatment of the eye in this disease, only what renders the disease of the kidney controllable is of advantage to the retina; leeching may be useful if the patient be not too anæmic. For the vitreous opacities, in cases where the disease is under control and the acute condition of the eye abated, electricity is of considerable value, much more so than any plan of medication.

"The microscope shows a sclerosis of the retinal fibres, the walls of the blood-vessels degenerated, fatty deposits along the fibres and in the layers of the retina, also in places a pigmentation; the choroidal vessels are implicated as well.

"Uræmic amaurosis is rare, Wagner finding one case in one hundred and fifty-three of Bright's disease. Graefe found two cases in thirty-two cases of albuminuric retinitis; it presents no retinal change that is recognizable.

"As yet we cannot tell why the retinal changes occur with disease of the kidney. Does the structure of the retina and its proximity to a highly-vascular tissue account for it?"

In the discussion on Dr. Little's paper, Dr. Albert G. Heyl said, "I desire to direct attention to the relation which exists between the intraocular phenomena observed in Bright's disease and the anatomical arrangement of the intraocular arteries. The latter are divisible into certain areas: thus, we have one area composed of the arterial circle of Zinn which supplies the optic papilla; another formed by the arteria centralis retinæ which supplies the retina; another composed of short posterior ciliary arteries which supply the pos-

terior half of the choroid; still another composed of the long ciliary arteries which supply the iris and the anterior half of the choroid; the short anterior ciliary arteries also take part in the formation of this area. Now, it is established that abnormal changes in connection with Bright's disease may exist primarily in each of these areas, with perhaps one exception, to be mentioned directly. Thus, the papillary area may be affected, and a papillitis will be found on examination, the choroid and retina and iris being unaffected. Again, the posterior choroid area may be affected, and there will be found the phenomenon of subretinal œdema, and also in the choroid the white accumulations so well known in connection with Bright's disease. Both of these forms are considered to be rare; perhaps they would be observed oftener were we more alert. A case reported by me (*Amer. Jour. Med. Sci.*, October, 1874) of retinal separation occurring in one eye, while simultaneously the other was affected by temporary amblyopia, probably belonged among the affections of the posterior choroidal area. Further, the retinal area may be affected, and the peculiar retinal appearances so well known are found. So far as I am aware, no separate affection of the irido-choroidal area has been described; there seems to be no reason why it should not occur. Of course there are many cases in which the areal lesions exist together, but they are to be looked upon as the result of one common cause, not as the result of a morbid process starting in one area and gradually implicating the others.

"In referring to the snow-like patches of the fundus, commonly looked upon as the characteristic intraocular appearance of Bright's disease, I think that to a certain extent they are to be looked upon as the remnants of intraocular hemorrhage. While hemorrhagic clots formed of normal blood are absorbed without any whitish residuum being left, the case is different where the blood, as it circulates in the vessels, is in a morbid state. Thus, in a case of pernicious anæmia I have observed a number of round red hemorrhagic spots with white centres. On examination, ten days later, the red coloring-matter of the hemorrhages had largely disappeared, leaving as a residuum white masses. Some of these were speckled with red points arranged in spindle-form like the hemorrhages of the retinal nerve-fibre layer. They were, however, simply the unabsorbed remnants of the round hemorrhagic spots seen ten days before. So in morbus Brightii the blood is in such a morbid condition that hemorrhagic clots rapidly lose their red coloring by absorption, leaving behind a white residuum, which may partially, at least, explain the white placques seen with the ophthalmoscope."

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, DECEMBER 27, 1883.

The President, DR. TYSON, in the chair.

Fracture of the base of the skull. Exhibited by Dr. GUY HINSDALE.

J. H. W., æt. 50, fell on the ice December 8, 1882, striking upon the stone pavement. The blow was received on the posterior and left side of the skull, and the skin was not broken. He was shortly afterwards admitted to the Episcopal Hospital, and was totally unconscious. Blood was found flowing from his mouth and left ear, and his nose contained clots. His pupils afforded no evidence of his condition, because of an iridectomy which had been performed on both eyes some years previous. He talked incoherently. Breathing was labored and at times stertorous. Paralysis of the left leg was noted.

The blood continued to issue from the left ear, and on the second day the discharge became thin, and continued serous until his death, which occurred on the eleventh day. The urine was examined several times, and found to contain sugar in moderate amounts, but no albumen. Urine was passed freely. The patient never regained consciousness. He became more stupid, and paralysis of the left leg remained.

At the autopsy, a superficial clot was found over the brain, beneath the seat of injury. A very large clot was found over the right frontal region, beneath the membranes, and filling the sulci between the convolutions. This was the result of the counter-stroke, the force having been first received at a point diametrically opposite, and fully accounts for the left-sided paralysis. The fracture was slightly over five inches in length. It extended from a point in the left occipito-parietal suture one and a half inches behind the temporal bone, and traversed the suture, passing through the petrous portion of the temporal, the auditory canal, close to the inner side of the foramen ovale towards the foramen rotundum, where it terminated.

Necrosis of the temporal bone, and brain-abscess. By Dr. GUY HINSDALE.

This specimen was removed from the body of Margaret P., æt. 46, who died in the Episcopal Hospital September 21, 1882, after long-standing aural disease.

In early childhood she had scarlet fever; this was followed by aural catarrh, and the discharge from the ear continued until her death. She stated that when 22 years of age a polypus could be seen in her ear. Fifteen years ago this was removed. Again masses were removed thirteen years, two years, and one year ago. In May, 1883, four months before her death, the patient consulted Dr. Burnett, who has very kindly furnished me with

notes of that date. The patient presented at that time a most wretched appearance. Extreme weakness, pallor, and emaciation betrayed the intense suffering of this unfortunate woman. Paralysis of the right side of the face had occurred during the previous winter without the supervention of additional ear-symptoms. At the time of examination she presented great sensitiveness of the auriculo-temporal nerve, and complained of intense pain over the right temporal bone. To control this pain she was accustomed to use morphia suppositories. An examination of the ear revealed a mass of granulations filling the entire lumen of the auditory canal, half an inch from the entrance. Late in May a large polypoid mass was extracted. Bare bone was then discovered on the posterior portion of the canal, the channel narrowed and blocked with granulations. About two fluidounces of blood escaped after removing this mass.

When I saw the woman at the hospital in September, she was in a very low state and evidently near her end. Her mind was seriously affected. Conversation was impossible, and she groaned with the pain which large doses of morphia could not altogether control. There was a moderate but constant purulent discharge from the ear and from a sinus which was found above the meatus. The whole temporal region was boggy. The probe passed in freely over an inch, and loose particles of dead bone could be everywhere felt. The disease had long been beyond the reach of any remedy, and there was nothing to be done but to relieve pain and await her death.

The specimen removed embraces portions of the right temporal, parietal, and occipital bones. Almost all the temporal bone has been destroyed. Only the mastoid process and the upper border of the squamous portion remain. An area of bone one and a half inches by two inches has entirely disappeared. Adjacent to this region and lying next to the middle fossa of the skull was a brain-abscess, the walls of which were greatly thickened. On opening this cavity, about an ounce of thick, yellowish pus was found. A probe easily reached this cavity through the auditory canal and the sinus above it, and many loose fragments of bone were found at the outlet. The styloid process was found loose, but held in position by the various ligaments that arose from it. The inflammatory process, in which the meninges had of course shared, was not acute. The brain-substance beyond the abscess-walls had no unusual appearances, and the left cerebral lobe, with its membranes, was normal.

Dr. C. H. BURNETT said the great destruction of bone-tissue is remarkable and unusual in extent, being three inches in length and one and a half to two inches in breadth. The necrosis seemed to have originated in

the tympanic region rather than in the mastoid, and hence belongs to the class of cases second in frequency,—the most frequent being those fatal cases where the bone-disease originates in and extends from the mastoid cavity. The case when seen by Dr. Burnett, in the spring of 1883, presented very grave symptoms, and the patient was extremely weak,—so much so that Dr. Burnett was surprised that she lived until September. The occurrence of extensive granulations in the external auditory canal constituted a very unfavorable feature, as they acted like a dam, preventing the escape of the products of inflammation, and held them back in the tympanic cavity and mastoid cells, forcing them to break an escape through more important and vital tissues. The case furnishes another example of the evil of neglect of purulent disease of the ear.

Dr. BURNETT inquired whether there were symptoms of destruction or implication of any of the nerves passing through the cavernous sinus, as would be shown by alteration in parts supplied by the oculo-motor, pathetic, and ophthalmic nerves, to which Dr. Hinsdale replied that no eye-symptoms had been ever detected.

Case of phthisis with empyema. Presented by Dr. H. M. FISHER.

The patient, J. C., æt. 21, was admitted to the Episcopal Hospital March 17, 1883. He states that he has had a slight cough for one year, but that he was not much annoyed with it until about one month ago, when he was seized with severe pain in the left chest, accompanied by chilly sensations and difficulty of breathing. Upon admission, he presented all the symptoms of left pleural effusion, absent vocal fremitus, tubular breathing, and bronchophony in the neighborhood of the spinal column on the left side. His chest was tapped on the morning of March 21, and three pints of a semi-purulent fluid were evacuated. The operation was followed by great improvement in the patient's symptoms. Three weeks later he left the hospital, contrary to advice. He was readmitted April 20, and stated that soon after leaving the hospital the pains in the side returned, followed by dyspnoea. April 23, paracentesis thoracis was performed by Dr. Henry, and fifty-six ounces of purulent fluid were drawn off, and the operation again afforded great relief. A violent fit of coughing followed the withdrawal of the canula. The heart's apex-beat was found, before the operation, to be immediately below the right nipple; after the operation it was found to have shifted one inch to the left of its previous position. May 5, Dr. Forbes operated at Dr. Henry's request, making two openings into the left pleural cavity, one at the fifth interspace, the other at the fourth and to the right of the first. Ten ounces of purulent fluid were withdrawn

by means of the aspirator, and a soft-rubber catheter was passed in at one of the openings and out at the other. The pleural sac was then ordered to be washed out daily with a solution of corrosive sublimate, gr. i-3i.

During the summer the patient's general condition seemed for a time to improve; his appetite, however, continued obstinately bad, and he had constipation alternating with diarrhoea. In October it was noted that he was losing flesh and strength rapidly, and that there was much oedema of the feet and legs. During this month diarrhoea became a constant symptom, and death occurred November 22.

Post-mortem examination, ten hours after death.—The body is extremely emaciated. The left lung is contracted to about one-fourth of its normal size, and contains in its upper lobe some cheesy masses, with areas of catarrhal pneumonic infiltration. The left pleural cavity contains about five ounces of ichorous pus. The parietal layer of the left pleura is so tightly adherent to the chest-wall that it is impossible to detach it without dissection. The pulmonary layer is also tightly adherent to the contracted left lung, the lobes of which are firmly matted together by adhesions. The right lung also presents numerous cheesy foci, with large areas of catarrhal pneumonic infiltration. The heart is rather small, and its tissue is pale, but its valves appear normal. The liver weighs six pounds six and one-half ounces; its tissue is pale, and it has a *markedly waxy appearance*. The spleen is much enlarged, its tissue *firm, and of a dusky-red hue*. Numerous *yellowish-white nodules* are also seen in it, the largest of which is perhaps of the size of a small pin's head. The kidneys are rather large, their capsule is non-adherent, and their tissue rather paler than normal. Numerous *minute whitish nodules* are also found to be scattered through the tissue of both kidneys. These appear rather more numerous and larger in the cortical portions, but are also found in the medullary portions. From some of the larger nodules a whitish puriform substance can be squeezed out with the blade of the knife. With the naked eye the exact nature of the above-mentioned infiltrations of the spleen and kidneys is difficult to determine. Nothing abnormal was noticed in the intestinal tract, except in the ileum, where an area of intense congestion was noticed about one yard from the ileo-cæcal valve, but no ulceration was anywhere detected.

My view of the sequence of pathological events in this case is the following: *first*, catarrhal pneumonia, with the production of cheesy foci; *secondly*, scrofulous inflammation of the pleura, with attendant exudation, which from the start was probably more or less purulent; and, *thirdly*, the infiltration of the *liver, spleen*, and possibly also the *kidneys*, with amyloid matter.

The exact nature of the yellowish-white nodules in the spleen and kidneys being yet undetermined, I cannot yet assign to them a positive place in the chain of scrofulous processes; but from the absence of any macroscopic evidence of embolic infarction or of any appearance of infarction in the one microscopic section of the kidney I had the opportunity of examining (kindly made for me by Dr. Henry), I should conclude that these were also cheesy foci, and their production may perhaps have nearly coincided in point of time with the production of the cheesy foci in the lungs above alluded to.

Dr. SHAKESPEARE said that the specimen was a good instance of miliary tuberculosis. The small collection in the spleen might be tuberculous, he thought, and should have been examined for tubercle-bacilli. He adverted to the successful employment of very weak solutions of corrosive sublimate in washing out suppurating serous cavities.

Atheroma, dilatation, and aneurism of the aorta; atheroma of some of its branches; death from rupture of the aneurism into the left pleural cavity; congenital deformity of the stomach; malposition of the transverse colon and right kidney; irregular shape of the kidney; anomalous origin of the renal arteries and of the ureters. By J. H. MUSSER, M.D.

These remarkable series of specimens illustrate how serious a disease can be in progress within the body without any manifestations. The patient had been under the care of Dr. Ludlow in the Presbyterian Hospital, complaining of, and being treated for, nasal catarrh. He complained also of a slight bronchitis, but, it not being very decided, the nasal trouble alone was treated. A white man, æt. 63, well nourished, of temperate habits, and by occupation a wheelwright; was under observation ten weeks; no previous illness. He slept well the night before his death until 5 A.M. He then told the night-nurse he was very cold. Being covered, he went to sleep apparently; an hour afterwards he was found dead. The writer made the autopsy about twelve hours after death.

Inspection.—Rigor mortis well marked; body well nourished; no scars or bruises; no ecchymoses; abdomen moderately distended; in the right lower quarter a decided swelling was noticed, almost filling that area, and resonant on percussion.

Section.—Abdominal cavity first examined. The above-described swelling was due to the cæcum and transverse colon. The ascending colon extended about half-way the usual distance, and then turned at a sharp acute angle into the transverse colon. The latter descended parallel to the former into the right iliac fossa, and from thence diagonally upwards across the abdomen to the usual place of junction with the descending colon. The

omentum contained a considerable amount of fat. The right lobe of the liver could not be seen until removal of the ribs, when it was found two inches above their margin, and to be only two and one-half inches in length in the nipple-line. In the median line this same perpendicular length was three and one-half inches. More of the left lobe was visible than of the right. Along the edge of the left lobe, from the median line, four and one-half inches in length, extended the *stomach*. It appeared to be small in size. When removed, it was found to be divided by a constriction five inches from the fundus; from this constriction to the pylorus the length was four and one-half inches. The first or cardiac end was much smaller than normal, the walls and mucous membrane healthy. The second portion was a mere tube with thick walls. The thickening was due to the hypertrophy of the longitudinal muscular layers, and to the folds that the mucous membrane was thrown into. These folds were very marked, longitudinal, and on their crests congested. The peritoneum was opaque and thickened. The *liver* was smaller than usual also. The capsule was thickened and opaque along the edges of the right lobe; on the superior surface there were cicatrices, and a firm adhesion at one point to the diaphragm. On section, the tissue was firm on pressure and congested. Commencing cirrhosis noted in microscopical examination. The *gall-bladder* projected one inch below the liver-margin in the nipple-line. The *left kidney* was found in its normal position. It was much enlarged, five inches long, two thick. Its pelvis was filled with fat, the substance pale, hard on pressure, with a contracted cortical portion. The capsule tore off easily. The *right kidney* was found in the pelvis at the right sacro-iliac articulation. It was small in size, irregular in shape, parallel to the os sacrum. The portion dipping downwards tapered to a point, being one-half inch in width; the upper portion was two inches wide. The pelvis of the kidney was filled with fat. Towards the small end of the kidney the pelvis divided, one part extending upwards one inch, along one side of the organ, the other the same length on the other side; or it might be said that a portion of the kidney dipped into the pelvis, separating it for an inch. The renal artery arose from the normal origin of the middle sacral. Therewith from the point of origin it divided; one branch, two and one-half inches long, entered one lateral hilus, if it may be so termed. The other divided two and one-half inches from the main trunk, one subdivision entering the remaining lateral hilus, the other running across the floor of the pelvis to the normal end of the kidney. The ureter arose by three branches,—two from the upper end, one from one of the smaller pelvis.

Thoracic cavity.—Left pleural cavity almost

filled with blood, the lung floating on the fluid. The lateral surface was adherent to what was the aneurism. On its removal, the collapsed sac was seen on the left side of the vertebral column. The heart and aorta were removed entire. *Heart* enlarged, left side especially, weight eleven and one-half ounces; measurements of left ventricle,—near base one and one-eighth inches thick, in the middle seven-eighths inch thick, at apex one-half inch thick; mitral valves a little thickened, aortic healthy; atheromatous processes were present in the aorta from its beginning to the celiac axis, and extended into the latter vessel, and also the innominate and carotid arteries. These processes included the sclerotic changes shown by innumerable small, smooth, firm elevations of the surface, the degenerative changes, fatty and calcareous, and also the atheromatous. One calcareous plate was found in the celiac axis. From its origin to the middle of the transverse aorta the vessel was dilated, and the characteristic fatty changes of the proliferated cells of the intima—lemon-yellow-colored, smooth, soft elevations—were marked. Opposite the trachea the calibre of the aorta diminished to almost normal size, and here the sclerotic changes were most marked, as well as around the mouths of the vessels. At the junction of the transverse and descending aorta the lumen was again closed; here the aneurism originated. It was five and one-half inches long, and, when distended, twelve inches in circumference. It was of the true variety; but from it sprang four false aneurisms, varying in size from a filbert to a small egg. Organized clots covered the surface of portions of the wall, and on dissection it was found that these clots were either connected within the false aneurisms or clinging to atheromatous ulcers. Rupture of the sac took place behind the pleural adhesions and leaked into the cavity, finding its way through the adhesions. The vertebræ were not eroded, and, although the sac was in contact with the left bronchus, there were no evidences of decided pressure upon it, while the relations to nerves, other vessels, and the œsophagus were such that the usual pressure-symptoms could not arise. It is thus seen that by physical examination alone could this aneurism have been detected. There were absolutely no subjective symptoms, and the autopsy reveals the reason of this.

Hour-glass contraction of stomach (congenital). Presented by J. H. MUSSER, M.D.

The patient, an adult, from whom I removed this stomach died of organic heart-disease. Constant vomiting occurred a few months before death, but as a sequence of the general condition of the patient, and not on account of the gastric change. I call the appearance congenital because of the absence in the clinical history of any occurrence throughout life to have caused it, and of the

want of evidence on post-mortem inspection. The contraction took place in the centre, and was transverse; the peritoneum and submucous connective tissue were thickened at this point. Anterior to the constriction the muscular coat was hypertrophied. The mucous membrane was thrown into folds in the constriction.

Lung from a case of pleuro-pneumonia complicated with delirium tremens. By J. H. MUSSER, M.D.

I present this specimen to-night on account of its perfection. It is the lower lobe of the right lung in the stage of red hepatization, as indicated by the appearance, weight, etc. Almost the entire pleural surface, including the diaphragmatic, is covered with recent lymph, the layer averaging one-half inch in thickness. The tongue of the lung dipping into the space between the diaphragm and the thoracic wall is not solidified entirely. Here the lymph is abundant and the contiguous portion of the lung is hepatized, as if the inflammatory process extended from the pleura. This peripheral hepatized portion is but one-fourth of an inch wide. The inner succeeding portion is not solidified.

The patient died eighteen hours after admission to the hospital, from heart-clot. When admitted, there were evidences of its formation, and in addition he had delirium tremens. The pneumonia was distinctly recognized. There were no signs of simple or diaphragmatic pleurisy. At the autopsy, on removing the sternum, the extreme distention of the right heart, especially the auricle, was remarked. On opening the heart, hypertrophied from other causes, the right side was found filled with blood, and an enormous ante-mortem clot entwined around the leaflets of the tricuspid valve and extending through the auricle into the pulmonary vessels. A similar clot was found in the left heart. The kidneys were congested, and commencing cirrhosis appeared manifest.

The history of the case antecedent to the admission to the hospital is as follows. The patient had been on a "spree" for two weeks and five days before admission, and had had a severe chill, followed by the symptoms of pneumonia. Two days after the chill the mania developed, and on the day of admission he had been found wandering about the streets by a crony, who brought him to the hospital. He was 41 years old, a boss machinist, single, of intemperate habits.

Carcinoma of the uterus, fatty kidneys, and emphysema. By W. A. EDWARDS, M.D.

The specimens which I show you to-night were taken from the body of A. E. this morning. I have not as yet had the opportunity of examining them microscopically. The patient was visited but once before her death by Dr. J. S. Watt, for whom I made the post-mortem examination. The history of the

patient is, of course, imperfect; in fact, little, if any, could be obtained. The symptom of which she complained the most was an ill-smelling, irritating discharge from the vulva: so our attention was first directed to the womb, which presents a scirrhus carcinoma of the external and internal os and of the cervical canal. The mucous membrane of the organ is softened and very rugous, looking not unlike a mammillated stomach. A microscopic section will probably show cellular infiltration. The uterus is enlarged. Our subject was a multipara, æt. 45, nine children and two miscarriages. A cyst was seen in the right parovarium; its contents were pure serum. The ovaries presented areas of calcareous degeneration; other pelvic viscera normal. The kidneys are small, and appear to have undergone some amyloid change; the right one was a rib higher than its normal position. Heart-muscle has undergone some fatty degeneration, as has also the aorta; valves almost normal; ante-mortem clots in each ventricle, that in the right of unusual size. Pericardium contained the usual straw-colored effusion.

Lungs.—Left, normal; right, the pulmonary and costal pleura were in many places adherent by thick, well-organized lymph, which beautifully illustrates the *rationale* of friction-râles, their sudden appearance, short duration, and equally sudden disappearance. About a pint of purulent effusion was collected in the base of right chest. The diaphragmatic pleura was tightly adherent to the pulmonary, requiring some tearing in order to separate it. The lobes of this lung are bound down by recent lymph. Scattered throughout the mesentery were to be seen areas of calcareous degeneration about the size of almonds.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

STATED MEETING, THURSDAY, JANUARY 3, 1884.

The President, R. A. CLEEMANN, M.D., in the chair.

BATTEY'S OPERATION.

DR. E. E. MONTGOMERY corrected a statement made in the report of the case of ovariectomy narrated by him at the meeting of December 6, 1883. *Silk ligatures*—not catgut—were used to tie the pedicles.

The convalescence of the patient had been very satisfactory. The temperature did not rise above 99° F. In performing this operation no antiseptic was used. All instruments, sponges, etc., were washed in boiling water, and boiled water was used in washing the wound and abdominal cavity. The mental condition of the patient was such that she

was kept constantly under mechanical restraint; and on one occasion, when she had been left alone for a few minutes, she tore all the dressings off the wound, and at the next visit it was found bare; but no bad result followed. The sutures were removed on the eighth day. Some pain in the lower part of the abdomen, and slight fever, commenced on the twenty-fifth day; but she has since again improved. Her mental condition is at the present better than it had been for a year before the operation, and she can now converse rationally.

SEPTICÆMIA AFTER ABORTION.

Dr. W. H. PARISH reported the following case. A young woman, 20 years of age, came into the Philadelphia Hospital in the finishing stages of an abortion which had been coming on for some days. The cause was unknown, but was probably instrumental. At the time he first saw her, three days after her admission, her temperature was 103° to 104° F., and her pulse one hundred and fifty. She had had a chill before admission. Her abdomen was distended and tender, and the uterus was very sensitive. The right parotid gland was swelled and painful. It continued to enlarge, and, fearing septicæmia, he gave her fifty grains of quinine daily, by rectum, as the stomach was too irritable to retain it. One ounce of whiskey was given by the mouth every hour, day and night. A small quantity of morphia was given to relieve the abdominal tenderness. The pulse and temperature fell rapidly, but the gland continued to be swelled and painful. It was quite hard, but was not discolored. There were no chills now, but, fearing the presence of pus, he made an opening by Hilton's method, incising the skin and using a director to tear an opening through the gland-tissue. This opening was enlarged by passing a pair of forceps, closed, along the groove of the director, and withdrawing them opened. This opening gave exit to two or three fluidrachms of pus. The gland now improved in appearance, but another abscess opened behind the gland and discharged freely. The two abscesses did not communicate. The patient is now convalescent.

OFFICERS OF THE SOCIETY FOR 1884.

President.—Richard A. Cleemann, M.D.

Vice-Presidents.—B. F. Baer, M.D., W. T. Taylor, M.D.

Secretary.—W. H. H. Githens, M.D.

Treasurer.—Alfred Whelen, M.D.

Librarian and Curator.—T. Hewson Bradford, M.D.

Councillors.—R. P. Harris, M.D., Lewis D. Harlow, M.D., William Goodell, M.D., T. M. Drysdale, M.D.

Publication Committee.—John H. Packard, M.D., James V. Ingham, M.D., Elliott Richardson, M.D., B. F. Baer, M.D.

NEW YORK PATHOLOGICAL SOCIETY.

A STATED meeting was held January 9, 1884, GEORGE F. SHRADY, M.D., President, in the chair.

TUBERCULOSIS OF THE TESTICLE.

Dr. A. G. GERSTER presented three different specimens, illustrating different stages of acute tuberculosis of the testes, which he had extirpated within a comparatively recent period. In the case of the first specimen presented, the patient had had hydrocele, for which Volkmann's operation was performed, resulting in the successful closure of the sac and the cure of the hydrocele. But five weeks later the patient returned, with symptoms of chill, sweats, loss of strength and flesh. Tuberculosis testis being recognized, ablation was performed, and the patient recovered from the aforementioned symptoms. Upon examination of the part removed, it was noticed that the central mass was hard but had not yet undergone the breaking-down process.

In the second case, the man had suffered from acute orchitis and epididymitis of traumatic origin. About seven weeks after the injury there were signs of tuberculosis of the testicle, with chills, sweats, loss of strength, etc. The hardened mass in this case had begun to break down centrally; and the tunica vaginalis, instead of being smooth and hard, was fungous, resembling the condition of the synovial membrane in tuberculosis of the joints.

In the third specimen the disease had become more advanced, the specimen being almost entirely broken down. The tunica vaginalis was almost obliterated. Dr. Gerster thought that tuberculosis of these organs was recognized earlier at the present time than formerly, and very properly led to the practice of early ablation. Formerly the idea prevailed that the organ should be let alone until finally it went on to a condition of so-called hernia testis. In none of these cases were signs of associated pulmonary tuberculosis discovered.

SPECIMEN OF LUNGS, LIVER, AND KIDNEYS
THE SEAT OF TUBERCULOSIS.

Dr. J. FURGESON presented the specimens, with the history of the case. The points of interest were—first, the absence of cavities in the lungs, which were the seat of very general tuberculosis; and, second, the excellence of the specimens of recent miliary tubercle pertaining to the liver and kidney.

Dr. E. C. WENDT remarked that some German observers had seen the tubercle-bacillus in the urine of patients suffering from tuberculosis of the kidneys.

PULMONARY AND NEPHRITIC TUBERCULOSIS,
WITH OBSCURE SYMPTOMS.

Dr. H. N. HEINEMAN presented the speci-

mens, which had been removed from a German, 29 years of age, who gave the following history. He entered the Mt. Sinai Hospital on the 23d of December last. There was no history of venery or of alcoholism in excess. His symptoms dated back four years, when he had pain in the region of the bladder, frequent urination, occasional vesical tenesmus. The urine was cloudy, but never contained blood. At times there was incontinence, while at other times the urine had to be withdrawn with the catheter. He also suffered some from backache, and had involuntary emissions at times, unaccompanied by erection. For four years previous to his marriage, which took place two years ago, he was addicted to masturbation. Nine months before admission, irregular chilly sensations developed. On admission, there was no cough, no pyrexia; there was emaciation, and râles heard over the chest, the signs pointing only to simple bronchitis. The urine was diminished in quantity and contained pus. The patient died six days after admission. The autopsy revealed recent miliary tuberculosis of the lungs, bronchitis, cirrhosis of the liver, and waxy spleen. The left kidney was eight inches long, four and a quarter inches wide, and weighed two pounds. The pelvis contained no pyogenic membrane. The cavities into which the kidney was divided were filled with pus and cheesy material. The ureter was greatly dilated. In the other kidney, the structure proper to the organ had almost completely disappeared under the influence of hydronephrosis. The bladder-walls were thickened and coated with pus. The prostate was broken down. Urethral stricture did not exist.

Dr. HEINEMAN said that the case was interesting inasmuch as there had been acute and chronic tuberculosis without fever. He, however, regarded this circumstance as of less frequent occurrence than did some physicians. The genito-urinary symptoms were of old date in this case, while the condition in the lung seemed to be of comparatively recent origin. It was probable, he thought, that the hydronephrosis in one kidney antedated tuberculosis; that, in consequence, the other kidney, having to do double work, became hypertrophied; and that upon this process there afterwards developed tuberculosis.

Dr. HEINEMAN also presented specimens from a child which had suffered from diphtheria, and, before the symptoms of this disease had entirely disappeared, pneumonia supervened, and afterwards empyema developed. The patient improved after the pus found exit from the pleural cavity, but the general condition was so low that death took place. At the autopsy, acute pulmonary tuberculosis was present, and pericarditis.

Dr. V. P. GIBNEY referred to a somewhat similar case, and spoke of the difficulty of recognizing the pericarditis.

Dr. HEINEMAN also presented a heart which weighed thirty-seven ounces and was the seat of hypertrophy and dilatation and of acute ulcerative endocarditis, but there had been no chill nor febrile movement. The case was specially interesting from the negative history.

Dr. BEVERLY ROBINSON presented a heart with a diaphanic interventricular septum. He also presented some specimens removed from a patient who during life had no cough nor expectoration, nor stethoscopic signs of pulmonary consolidation, although at the autopsy there existed well-marked hepatization. On the other hand, the heart was normal, whereas during life there had been a distinct murmur pointing to aortic stenosis. The kidneys were the seat of chronic interstitial nephritis; and the question arose whether this form of Bright's disease could have been due to the existence of a slight urethral stricture. There was no cystitis.

Dr. PEABODY and Dr. FURGESON replied that they believed the cystitis was, as in many other cases, independent of the urethral stricture.

LESIONS OF PERNICIOUS INTERMITTENT FEVER.

Dr. G. L. PEABODY presented the brain, liver, and spleen of a man who had recently died of pernicious intermittent fever, probably contracted in the West Indies, from whence he had arrived on the 1st of January. There was no elevation of the temperature until just before death. He entered in a state of apathy; coma developed, in which condition he died. The organs presented were deeply stained with blood-pigment. In the brain this was confined to the lumen of the blood-vessels. The same was probably true of the liver and spleen, although less easily demonstrable.

REVIEWS AND BOOK NOTICES.

RECHERCHES CLINIQUES ET THÉRAPEUTIQUES SUR L'ÉPILEPSIE, L'HYSTÉRIE ET L'IDIOTIE. Par BOURNEVILLE, Médecin de Bicêtre, et BONNAIRE et WUILLAMIE, Internes. Paris, 1882.

This book of nearly two hundred pages is composed of an annual report of the medical service for epileptics and idiots in the Bicêtre for 1881, and of observations made in this hospital upon various cases. The extent of the field for observation may be judged of from the fact that at the beginning of the year there were one hundred and fifty-two adults and one hundred and twenty-six infants in the wards. A curious and not very creditable incident of the year was the syphilitic infection of a number of the male children by a nurse of pederastic tastes and practices.

The notes on idiocy occupy some fifty pages,

filled with most elaborate clinical and post-mortem notes of cases arranged pathologically under headings of sclerotic hypertrophy of the convolutions, meningo-encephalitis, and microcephalic development; and some of the cases are very well illustrated by lithographic plates.

A long account, with numerous thermometric reports, is given of an epidemic of measles which occurred in the hospital during the year. Among what may be called miscellaneous cases we notice a very interesting account of a well-pronounced typical hystero-epilepsy occurring in a boy and cured by the conjoint use of repeated cold douches, given, twice a day, for from thirty to forty seconds by means of a rain and jets (lateral?), gymnastic exercises, and the monobromate of camphor. Several cases are detailed in which the bones or joints were affected in persons suffering from nervous disease, and the fact that the victim of locomotor ataxia may simultaneously suffer from rheumatism is clinically established, whilst the differences between such arthropathies and those of trophic origin are clearly pointed out. A case of osteomalacia with epileptic convulsions in a woman whose autopsy showed no cerebral disease is of interest, as bearing upon the question of the existence of the neurotic temperament without definite nerve-lesion. Intestinal lesions and bone-disease existed, and there was a family history of severe nervous diseases in the immediate families of both father and mother, whilst nine sisters or brothers had had convulsions. With such an inheritance of weak, uncertain nerve-centres, peripheral lesions or general malnutrition seems sufficient to awaken an epilepsy.

Enough has been said in regard to the brochure before us to show its character and scope; it is a valuable record of well-observed, carefully-detailed cases, a storehouse of laboriously observed disconnected facts,—the bricks, so to speak, out of which is built the great temple of medical knowledge; not a systematic popular treatise, but a book for the few who think and systematize upon observations made by others as well as by themselves.

H. C. W.

PHYSICIANS' VISITING LISTS.

"The Medical Record Visiting List, or Physician's Diary for 1884," published by William Wood & Co., New York, contains, in addition to the usual tables, metric system, etc., articles upon the proper doses of drugs for hypodermic use, by the mouth, and inhalation; on disinfectants, the urine, poisons, emergencies, on asphyxia, and other topics required for immediate reference. The dates are consecutive, a week to a page, the paper is good, the book being gilt-edged and bound in soft Russia, fastening with a rubber band if desired.

"The Physician's Visiting List for 1884," by Lindsay & Blakiston, is now in the thirty-

third year of its publication, and will need no extended comment. It contains the usual introductory matter, including a Posological Table and Silvester's Method for Artificial Respiration. It is dated like the preceding, strongly bound, fastening with a flap, and is a useful book.

"The Physician's Daily Pocket-Record, comprising a Visiting List, many Useful Memoranda, Tables, etc.," by J. W. Butler, M.D. A new and thoroughly revised stereotype edition, with Metric Posological Table, etc. Edited by D. G. Brinton, M.D. This book fastens with a clasp, and is strongly bound: it is now in the eighteenth year of continuous publication. The introductory matter is more extended than in either of the foregoing. The Posological Table, the article on Treatment of Emergencies, and the Table of the Urine, are especially noticeable. The arrangement of the visiting list, also, is different. While each double page is devoted to one week, the figures are not introduced, so that it may be used for any week or any year. The pages are numbered, so that an index may be made at the end for easy reference in making out accounts. It also contains a good Obstetric Record, and one of deaths and vaccinations, besides the usual memoranda and cash accounts.

GLEANINGS FROM EXCHANGES.

MYXŒDEMA.—At the meeting of the Clinical Society of London, on November 23, an interesting debate took place upon the subject of myxœdema, in which Sir W. Gull, Dr. Ord, and other observers whose names have been associated with our knowledge of the disease, took part. A valuable communication was made by Dr. Felix Semon of a series of cases of myxœdema occurring after extirpation of the thyroid gland, by Prof. Kocher, of Berlin, who, not being acquainted with the disease as such, had described his cases as a peculiar form of cachexia: in sixteen instances of complete removal the myxœdematous changes had been observed, whilst in the cases of partial removal the results upon the general health had been satisfactory. The previous belief in the intimate connection existing between the loss of the thyroid gland and the development of myxœdema was undoubtedly strengthened by the evidence which the discussion called forth, but it was no less evident that there are at present no facts extant by which the nature of that connection can be determined.—*Medical Times and Gazette.*

A CASE OF IDIOPATHIC GANGRENE OF THE UTERUS.—A paper, by Mr. Lawson Tait, was read before the Obstetrical Society of London (November 7), containing an account of a remarkable case. The patient, aged 34, was

admitted into hospital on account of vague pelvic pain and offensive watery discharge. The uterus felt soft and flabby, the abdomen was swollen, and there were feverish symptoms. The patient died forty days afterwards, and on post-mortem the uterus was found a black, sloughing, stinking mass, having only about a square inch of normal tissue. No reason could be discovered for the gangrene. No operative treatment was permitted, or else it would probably have been quite easy to remove the dead uterus by abdominal section.—*Medical Times and Gazette.*

CIMICIFUGA IN EPILEPTIFORM NIGHTMARE.—Dr. Ed. M. Small, of Eastport, Maine, sends us the report of a case occurring in his practice almost identical with one published recently in these columns in the report of Prof. H. C. Wood's clinic. The disease was epileptiform nightmare, and it was cured in Dr. Small's case by half a teaspoonful of powdered *cimicifuga racemosa* being administered at bedtime. The paroxysms at once ceased, and there had been no return in a lengthy period of observation. The patient also was ordered to partake of only a light supper each night.

MISCELLANY.

THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.—The annual meeting of this Society will be held at Philadelphia on May 14, 15, and 16, 1884, in the assembly room of the Union League, Broad and Walnut Streets. The President's reception and the entertainment by the Philadelphia County Medical Society will be held on the evening of May 14, at the Pennsylvania Academy of the Fine Arts, Broad and Arch Streets.

The by-laws require the programme of the meeting to be printed and distributed at least one month before the date of the meeting, and no voluntary paper is allowed to occupy more than twenty minutes in its reading.

Notice is hereby given that all those who wish to present papers should send the full title and a short abstract of the same to the Committee on Arrangements on or before March 1, 1884, in order that a varied and attractive programme may be prepared.

No paper will be selected for a position upon the programme of the meeting unless an abstract has previously been seen by the Committee.

JOHN B. ROBERTS, *Chairman*,
1118 Arch Street, Philadelphia.

By order of the Committee.

THE second annual meeting of the National Association for the Protection of the Insane and the Prevention of Insanity was held in this city on January 22, when the

following officers were elected for the ensuing year:

President.—Dr. Joseph Parrish, of Burlington, N.J.

Secretary and Treasurer.—Dr. Charles L. Dana, of New York.

Executive Committee.—Dr. Parrish, Dr. Dana, Dr. Edward C. Seguin, of New York; Dr. J. C. Shaw, of Brooklyn; Dr. Alice Bennett, of Norristown; Dr. W. B. Atkinson, and General John F. Hartranft, of Philadelphia.

The annual report of the Executive Committee on Finance and of the editors of the *Quarterly Journal* was read, after which the members were entertained at luncheon by Dr. Atkinson.

A NEW SOCIETY FOR THE CULTIVATION OF MEDICAL JURISPRUDENCE.—A meeting of a number of invited gentlemen, representing both the legal and medical professions, was held at the hall of the College of Physicians, Friday evening, January 18, 1884, for the purpose of forming a permanent organization for the study of forensic medicine. Prof. S. D. Gross was called to the chair, and announced the object of the meeting. Prof. Henry Leffmann was appointed Secretary. Among those present were W. S. W. Ruschenberger, M.D., John H. Packard, M.D., J. J. Reese, M.D., Albert H. Smith, M.D., Samuel Wagner, Esq., Charles K. Mills, M.D., L. P. Pritchett, Esq., Hampton Carson, Esq., and Frank Woodbury, M.D. It was resolved to form a society for the objects stated, and a committee was appointed to draft a constitution and by-laws. The next meeting will be held on the third Tuesday in February, when the permanent organization will be completed. About fifty members of the Philadelphia bar, and thirty physicians of prominence of this city, have already expressed their desire to join the Association.

PROF. WOOD'S LECTURE ON "DOCTORS AND HOW THEY WORK."—The second of the course of popular lectures given at Association Hall, under the auspices of the University of Pennsylvania, was given on Friday, the 18th instant, by Prof. H. C. Wood, who discussed the *raison d'être* of medicine-men and the methods of a past age as compared with those of the present day. Incidentally, homœopathy, or, more correctly, Hahnemannism, was considered, and, although declared in itself to be absurd and false in its claims, yet it was said to have exerted a great influence in the genesis of modern medicine, by demonstrating the recuperative powers of nature, and the benefits of doing nothing rather than adopting heroic medication in self-limited diseases. The lecture-hall was filled by an intelligent and attentive audience.

THE ANNUAL MEETING OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY was held

January 2, when the following officers were elected for the ensuing year: William M. Welch, President (second term); William S. Forbes and S. R. Knight, Vice-Presidents; Henry Leffmann, Recording and Reporting Secretary; M. S. French, Corresponding Secretary; L. K. Baldwin, Treasurer; C. M. Seltzer, Librarian; H. St. Clair Ash, Censor. Among the candidates to be balloted for were the names of two women physicians, who failed to get the required two-thirds vote.

NOTES AND QUERIES.

A SCRAP OF HISTORY OF PERKINS'S TRACTORS.

The publication of a new edition of Dr. Holmes's "Classical Essays on Homœopathy and Kindred Delusions" revives a temporary interest in Perkinism. The following hitherto unpublished extract may give a faint idea of the state of mind that prevailed in this country at the time this delusion prevailed. It is kindly contributed by Dr. W. Thornton Parker, and is an extract from a letter from Dr. Benjamin Parker to his son, Dr. W. Thornton Parker, Sr., dated November 11, 1842:

* * * * *

"I am much pleased with Holmes for the most part; but I have not had time to read him through. All about Perkinism is perfectly correct and true. I lived in those times, and was in the midst of the excitement. A gentleman in Virginia sold a plantation and took the pay for it in tractors, which tractors died on his hands. Nothing was more common than to buy horses and carriages with Perkins's tractors. But the worst effects of the delusion Holmes has silently passed over. The yellow fever prevailed in New York to a great degree, and proved fatal to thousands. Perkins thought he could cure the fever with his tractors, and went into the city while raging, and, as might be expected, he immediately fell a victim of his own folly."

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM JANUARY 5, 1884, TO JANUARY 19, 1884.

BROWN, P. R., CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty at Fort Huachuca, Arizona. Paragraph 9, S. O. 119, Department of Arizona, December 27, 1883.

BREWSTER, W. B., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Resignation accepted by the President, to take effect February 7, 1884. S. O. 10, A. G. O., January 12, 1884.

EGAN, P. R., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Upon reporting of relief, to proceed without delay from Fort Huachuca, Arizona, to Fort Apache, Arizona, and report to the commanding officer for duty at that post. S. O. 119, Department of Arizona, December 27, 1883.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING WEEK ENDING JANUARY 12, 1884.

Surgeon D. McMURTRIE ordered to the Naval Rendezvous, Philadelphia, Pa.

Surgeon A. F. PRICE detached from the receiving-ship "St. Louis" on the 15th and ordered to the U.S. steam-ship "Ossipee" on the 22d.

P. A. Surgeon A. C. H. RUSSELL ordered to the U.S. steam-ship "Ossipee" on the 22d.

P. A. Surgeon H. C. ECKSTEIN detached from the Naval Hospital, Philadelphia, and ordered to the receiving-ship "St. Louis."

P. A. Surgeon HOWARD WELLS from the Naval Rendezvous, Philadelphia, and ordered to the Naval Hospital, Philadelphia.

PHILADELPHIA MEDICAL TIMES.

PHILADELPHIA, FEBRUARY 9, 1884.

ORIGINAL COMMUNICATIONS.

THE BACILLUS TUBERCULOSIS AND THE ETIOLOGY OF TUBERCULOSIS.—IS CONSUMPTION CONTAGIOUS?

SECOND COMMUNICATION.

*Read before the Philadelphia County Medical Society,
November 14, 1883,*

BY H. F. FORMAD, B.M., M.D.,

Lecturer on Experimental Pathology and Demonstrator of Morbid Anatomy in the University of Pennsylvania; Mütter Lecturer in the College of Physicians of Philadelphia.

GENERAL CONSIDERATION.

A LITTLE over a year ago* I had the honor of presenting for your consideration some anatomical points in refutation of the etiological relations of the bacillus tuberculosis.

At that time I announced some original observations regarding the histology of scrofulous tissue, tending to place the question of heredity in tuberculous disease upon an anatomical basis. These peculiarities of scrofulous tissues I submitted as elucidating the etiology of tuberculosis, showing that the peculiar histological condition of the individual, under the influence of simple irritants, and not the character of the irritant, is responsible for tubercular inflammation. It gives me pleasure to state that these observations have since been confirmed by several competent histologists, whose articles on this subject will soon appear in print; besides which a general interest has been manifested by favorable comments both in America and abroad.

Shortly before the publication of these observations, Koch, of Berlin, had brought forward the discovery of the now famous bacillus tuberculosis, affirming it to be the sole cause of pulmonary phthisis and other forms of tubercular disease, and claiming for it, besides exclusive pathogenetic properties, special morphological and chemical characteristics.

In my first paper I denied some of these propositions upon grounds of personal investigation, and subsequently Koch's re-

searches were also severely criticised by a number of other observers.

As interesting and valuable as the discovery of Koch is, from a biological stand-point, its practical value is decidedly overestimated, and has, in my opinion, not nearly the significance for medical science which the enthusiastic followers of Koch ascribe to it. The influence of the discovery was, however, great in strengthening the traditional and unwarranted belief in the contagiousness of phthisis, as held by a small part of the profession and community. On the other hand, this belief led to the popularity of the discovery. In this respect the bacillus theory has perhaps been harmful, and, taking the consequences into consideration, we should not accept such a theory without the closest scrutiny.

Two practical benefits may accrue from this discovery. The first is that the fear of the effects of the bacillus may induce greater cleanliness in hospital management and enforce improvement in hygienic matters in general. It is doubtful whether the removal and prompt destruction of the sputum would have any influence in checking the spread of phthisis, as the disease is found as often, if not oftener, in the clean palaces of the wealthy as in the unclean huts of the poor. The second advantage resulting from the bacillus theory may be that physicians may become induced to make more use of the microscope in diagnosis; yet in this respect the general use of the microscope is hardly practicable, on account of the thorough technique and experience required.

To-day, while the bacillus is acknowledged as a common morphological concomitant of tubercle, the pathogenetic properties are denied it by the best pathologists and clinicians, on account of a want of sufficient confirmation of the evidence thus far offered. The followers of Koch's theory are, however, numerous, but they are recruited largely from the ranks of clinical teachers, book-writers, and others possessing no opportunities for personal investigation.

It may be well to state that, upon my visit to Koch last summer, made with the purpose of doing justice to this important question, I was gratified in many respects. I found Koch an earnest and conscientious worker, and not as dogmatic and extreme

* Studies from the Pathological Laboratory of the University of Pennsylvania, xi.; "The Bacillus Tuberculosis and some Anatomical Points which suggest the Refutation of its Etiological Relation with Tuberculosis, by H. F. Formad," Philadelphia Medical Times, vol. xiii. p. 109.

in his views as would appear from his writings; nor is he as self-satisfied and as rash to jump at conclusions as are some of his followers. Koch has the co-operation of an excellent staff of assistants, all able mycologists; but it was a matter of surprise to me that there was not a single competent pathologist connected with his laboratory; and such services are evidently much needed to give to the observations made there the proper interpretation from a biological and anatomical stand-point. I was also pleased to learn in Berlin that the discovery of the bacillus was exaggerated not so much by Koch himself as by the Imperial Board of Health, which employs him, and by his over-zealous followers in the profession. There is strong evidence, however, that Koch's investigations are biased by the determination to find for each specific disease a specific fungus.

Following out the various phases in the study of tuberculosis, I am sorry to see that the entire subject is now being considered from a purely etiological basis with reference to bacteria, while the study of the anatomical and biological relations is wholly neglected.

I admire the beautiful bacteridian discoveries of Klebs, and particularly those of Koch in connection with the etiology of tuberculosis. The accomplishment of these results is a triumph for scientific botany and mycology; but these studies are much too one-sided to have an application to scientific medicine. The bacillus is there. It is concomitant with most tubercular lesions. It is diagnostic of tuberculous change. It is, on account of its irritant properties, one of the causes of tuberculosis. But this forms no reason for asserting that tuberculosis should be considered a contagious disease, without further investigation and proofs. A contagious disease can have only one cause. I cannot agree with those who define the predisposition to phthisis as being a condition of the organism which offers a favorable soil for the tubercle-bacillus. Nor can I believe that inheritance is explained by subsequent infection from cohabitation, *e.g.*, that children become scrofulous by living with consumptive parents.

The latest fruits of the bacillus studies have even inspired Baumgarten (*Centralblatt f. d. Med. Wis.*, Aug. 4, 1883) and several others to come to the conclusion,

in reference to the hereditary nature of tuberculosis, that the bacillus is transmitted in its larval state from mother to fetus in intra-uterine life! One would think, however, that one of the most wonderful effects of the tubercle-bacillus is manifested by the change it produced in the direction of reasoning powers of some of our pathological and clinical investigators, both at home and abroad. Some of the younger pathologists are even affected by a regular fanaticism for bacterian studies in tuberculosis. These studies now take the place of their former excellent pathologico-anatomical studies. Consideration is no longer given to the tissue-changes, or the nidus which invites the bacteria and nourishes them. In fact, Koch's followers in their enthusiasm exaggerate matters, and, to Koch's own amusement, go further in their bacillus speculations than he himself thinks justifiable. It is really painful to read how some of the younger German pathologists and a few of the prominent English surgeons, under the influence of the bacillus craze, will make in their publications assertions entirely unwarrantable. They describe, for instance, with the greatest ingenuity and exquisite minuteness, how "one or more bacilli" will produce certain histological changes in the lungs or in the peritoneum, designating the exact route to the same; how the different cells, the lymphatics, and the blood-vessels are affected; how the bacilli convert one variety of cells into another; how they manufacture giant cells and cheesy material; how acute and chronic phthisis is produced by the bacilli, and the quantity necessary for each; how tubercles develop only and exactly in those places where the bacillus becomes lodged; how, if bacilli alone are inhaled, miliary tubercles form; and how, if the bacillus is accompanied by some other irritants, a broncho-pneumonia will ensue.

All of the above statements are made by scientific medical men and pathologists, and offered as broad facts in full earnest! I only have to say that here evidently observation is substituted by imagination and mere speculation; and all this is done for the sake of the convenience in explaining a disease by pretty hypotheses.

The only men who attempted to repeat Koch's experiments, besides the work done in the pathological laboratory of the University of Pennsylvania, were Spina (*Studien über Tuberculose*, Wien, 1883)

and Watson Cheyne. Of the latter two scientists, Spina came to results entirely different from those of Koch, and they disprove beyond doubt some parts of Koch's hypothesis. From an analytical and critical point of view, Spina's studies of tuberculosis are excellent, but the technical part of his investigation is deficient, and hence not satisfactory. Watson Cheyne, to whom the "British Association for the Advancement of Science by Research" had intrusted the investigation of tuberculosis and the testing of Koch's researches, did not do justice to his mission. From Cheyne's report (*The Practitioner*, April, 1883) it is seen that he made no earnest attempt to study the nature of tuberculosis, because all he did was to study and experiment with bacteria met with in tuberculous lesions. He went to see some of the different mycologists, consulting only believers in the germ theory; obtained some French and German bacteridian material, and, after testing the same, he reports with great emphasis that Koch's bacilli are a more genuine tubercular virus than Klebs's or Toussaint's micrococci. He did not inquire, nor did he care, whether tuberculosis may have any other cause! He simply imitated some of Koch's experiments with the bacillus material in rabbits and guinea-pigs (only), and obtained, of course, the same results. Furthermore, he made some control experiments, which, as I will show, pass for naught, as they are much more deficient than those of Koch.

There are a number of excellent studies in reference to the occurrence of bacilli in the sputum and in tuberculous tissues; but the main part of Koch's hypothesis, *i.e.*, the etiological relation of these bacilli to tubercular disease, remains still unconfirmed.

My own researches on tuberculosis were made from a stand-point different from that of Koch, and they were undertaken five years ago, being carried on continuously since that time by myself and assistants. My object was to investigate the natural history of the disease, without being influenced by any preconceived views. While due attention was paid to external agencies in the production of tuberculosis, the part played by the animal or human organism itself, the behavior of its component cells, and the primary

changes in the tissues were not lost sight of.

I may state that I was fortunate enough to be able to utilize the material of over four hundred cases of tubercular disease from the autopsy table, including a number of cases studied in the pathological institutes in Europe at various times.

My present research on tuberculosis, with special reference to the bacillus question, was carried on during the last year and a half, under the auspices of the provost of the University of Pennsylvania, Dr. William Pepper. This communication should not be considered a report on my investigations, as these are not yet concluded; but a detailed report of these investigations will be made next summer. Some of the positive results achieved will, however, be referred to in the present paper; otherwise it merely embodies a general critical survey of the question of the etiology of tuberculosis, based upon a careful perusal of the literature of the subject and upon personal observation.

I may state, at the outset, that while the results of my observations force me to-day to make some concessions to Koch, namely, that his bacillus, on account of its irritative properties, can produce tuberculosis under certain conditions, I am firmer than ever in my former conclusions, from the results of repeated observations, that tuberculosis may arise from other causes. The bacillus may be one of the causes, conditionally, but it is not THE cause. The question of predisposition stands in the way of the acceptance of the bacillus theory. Furthermore, I will try to show that tuberculosis is not a contagious disease, and it is particularly in reference to this that I am glad to bring the present subject before the Society, desiring to profit by the discussion which is to follow as a result of the experience and the clinical observation of the individual members of the Society.

The question of the contagiousness of phthisis is one of supreme importance, not only from its scientific but also from its social aspects.

For convenience in treating the subject of the etiology of tuberculosis, I shall speak of it under the following headings:

1. The definition, the anatomical character, and the etiology of tubercular lesions, including pulmonary phthisis.

2. The predisposition; the predisposing conditions; scrofulosis.

3. Tuberculosis without predisposition, due to inflammation of serous membranes.

4. Question of contagiousness; clinical aspect.

5. The bacillus tuberculosis.

6. Experiments "pro" and "contra;" traumatic tuberculosis.

Conclusions.

All these considerations will have to be of necessity very brief.

1.—THE DEFINITION, THE ANATOMICAL CHARACTER, AND THE ETIOLOGY OF TUBERCULAR LESIONS, INCLUDING PULMONARY PHTHISIS.

No definite understanding concerning a disease can be arrived at unless some fixed conception of the anatomical characters and various expressions of the lesions of that disease is formed. Thus, as regards the question of tuberculosis and pulmonary phthisis, the matter would be much simpler if a general understanding could be arrived at as to the definition of tuberculosis and phthisis in its different anatomical manifestations. The pivot of the question is what to call a tubercle or a tubercular lesion.

The traditional conception of a tubercle being a miliary node, the belief is that nothing is tuberculosis unless expressed by nodes, and that everything is tuberculosis that appears to the eye as containing nodes. These misconceptions are what bring the confusion and prevent the settlement of the question of tuberculosis, both at the post-mortem table and in the hands of the experimenter.

One of the results of this confusion is that some clinicians divide pulmonary phthisis into catarrhal, cheesy, fibroid, and tubercular proper, because they do not see tubercle nodules in some of these forms of phthisis. They seem not to be aware of the fact that miliary tubercles do not belong necessarily to the picture of pulmonary phthisis; and, on the other hand, that those nodes which occasionally appear as miliary tubercles are not miliary tubercles at all, but are only miliary foci of broncho-pneumonia, due to aspiration, as will be explained later. Miliary tubercles, if at all present, usually form a part of a general disease, a tuberculosis of the whole body. In rare instances, when the miliary eruption takes its departure from the lung, the miliary nodules may be limited to the lung.

A more serious matter is the mistake that

experimenters make of interpreting as tubercles the so-called inhalation tuberculosis, artificially produced in animals by means of a spray with tuberculous and other matter. The nodules produced in the lung under these circumstances are not miliary tubercles,—in fact, no tubercles at all. They are simply miliary broncho-pneumonic foci, limited to those terminal collections of air-vesicles, called acini, in which some of the inhaled irritative material became lodged. The natural round boundaries of these acini correspond exactly to the usual size of miliary tubercles, and appear as such even under the microscope, although filled merely with an unorganized inflammatory exudate. The uniform distribution of these foci is due to the fact that the inhaled irritating particles are distributed only to individual and the most accessible bronchioles and acini, thus simulating a true miliary tuberculosis of the lung. Similar broncho-pneumonic foci occur in the human lung from self-aspiration of tuberculous material from a primary focus to some other portion of the lung or throughout the whole lung. This was proved long ago, but the inhalation experimenters appear not to be aware of that fact. Careful personal observations and experiments, to be recorded in my forthcoming report, have convinced me that such inhalation experiments prove nothing, either for or against the contagiousness of tuberculosis, in connection with which they have been brought forward as the strongest affirmative proofs. Furthermore, it must also be remembered that the so-called experimental inhalation tubercles, as a rule, remain local.

On the other hand, miliary nodes or tubercles are met with, not only in tubercular lesions, but also in a variety of similar and dissimilar lesions, such as pearl disease or bovine tuberculosis, lupus, leprosy, glanders, actinomycosis, chancre and gummata, cancer, typhoid infiltration, lymphomatous and leukæmic lesions. All these lesions, even cancer ("miliary carcinosis"), are able to give rise to exquisite miliary disseminations, or eruptions, although these are most frequently observed in tuberculosis. We already recognize leprous, lupous, glanderous, syphilitic, and other tubercles, in contradistinction to tuberculous or scrofulous tubercles.

To the above nodular formations may be added a variety of minute inflammatory

foci of granulation tissue, organized around minute foreign bodies introduced experimentally into various tissues; also, "false tubercles," such as mere unorganized collections of lymphoid cells, held together by some fibrine or by some artificial or natural round boundaries, such as is the case with the referred-to "inhalation tubercles;" and further, also, the eruption and follicular enlargements in the skin and mucous membranes.

The question now arises, how to distinguish between these various kinds of nodules, apart from their clinical features. They may all undergo a cheesy or a fibrous change, may calcify, and may contain giant cells. In all, bacilli may be found if a cheesy change occurs, or tends to occur, save in cancer and in leukæmic formation. Without desiring to appear sceptical, I must say, however, that it takes the skill of a Koch to differentiate sometimes the bacilli met with in the various kinds of nodes, even after applying all micro-chemical tests.

The true tuberculous tubercles occasionally do not show any bacilli whatever, as I will prove from personal observation, and from the reliable testimony of others. It will also be shown that the only test now left for determining the pathogenic peculiarity of tubercle—namely, the asserted exclusive property to produce tuberculosis—is conditional and uncertain, since substances not tuberculous may, under similar conditions, have the same effect.

Therefore, it is impossible to define tuberculosis, either by its anatomical peculiarity or by the pathogenic property of its nodes.

Another important point in the natural history of tuberculosis is the cheesy degeneration of its products; but here, again, we are surrounded by difficulty if we take only the cheesy product into consideration, because all the lesions mentioned before as being characterized by, and as being capable of, nodular eruptions, have the tendency to undergo cheesy change. Besides this, simple inflammatory products have been observed to undergo a similar change, as is instanced by that form of cheesy hepatization sometimes following croupous pneumonia, and also by certain forms of rapid necrotic changes, such as occur in acute septic inflammations, designated lately by the name of "coagulation

necrosis." It must, however, be remembered that the total absence of cheesy masses in the body of tuberculous subjects has been observed.

To tell tuberculosis from allied lesions is only possible after a consideration of the soil in which it develops, and the location of the products, together with the clinical and anatomical manifestations.

What is the origin of tubercle nodules?

The primary occurrence of miliary tubercle nodes is, to my mind, very questionable. I have never seen it occur without the coexistence of diffuse granulation tubercle. This granulation tubercle is recognized by all as being a simple inflammatory granulation tissue, characterized by cells somewhat larger than ordinary lymphoid cells, containing usually giant cells, but undergoing very readily cheesy change on account of its deficiency in blood-vessels. This tissue is regarded by most pathologists as secondary to miliary tubercles; but I think, after careful observation, that the reverse is the case; because I have never seen upon the post-mortem table, or in animals, *primary miliary tubercle* nodes without the granulation tissue, while the granulation tubercle tissue does exist very frequently without the nodes. Moreover, primary *miliary* tuberculosis is unknown.

That tubercle is primarily a simple granulation tissue of inflammatory origin has been proven experimentally. E. Ziegler (*Centralbl. f. d. Med. Wis.*, 1874, No. li.) made the following interesting experiment. He inserted below the skin or into the peritoneum of animals, a number of pairs of glass covers, each pair glued together in such a manner that between them there existed an interspace just large enough to allow the entrance of white blood-corpuscles: and these corpuscles, not being severed from the body of the animal, then formed a tissue between these plates of glass, which, upon removal after various periods, could be readily examined under the microscope, and the conditions of tissue-formations traced. Under these circumstances it was observed that whenever blood-vessels had developed in the new-formed tissue between the glass plates, an organization of the cells into a perfect connective tissue took place; but, when the formation of blood-vessels had failed to occur, then a tissue simulating tubercle

tissue was formed, made up of epithelioid and giant cells, and cheesy changes had occurred. Ziegler very properly declared the latter product to be tubercle tissue. I have had, and have at present, ample opportunity to corroborate the accuracy of these observations. Ziegler's experiments were repeated in the pathological laboratory of the University of Pennsylvania, by Hammer, and at present are being carried on by Woodnut. By these experiments, made, with slight modification, after the method of Ziegler, under varying conditions and upon various animals, it was shown that the granulation tissue gradually gave origin to tubercle nodules. Furthermore, these experiments showed that the tubercle nodes and cheesy changes ensue without the action of bacilli, as the latter were found not to be present when proper care was taken, during the execution of the experiment, to exclude them.

From the examination of tubercular tissue from various sources, I may say that I have seldom succeeded in finding tubercle bacilli in newly-formed tubercular tissue made up of small lymphoid cells. In older tubercular tissue, made up of opaque epithelioid cells and giant cells with a nodular arrangement, particularly when this tissue is undergoing necrotic change, bacilli are quite common, except in some forms of tubercles of serous membranes, to be referred to later. Tubercle tissue that has undergone a complete cheesy change contains the greatest number of bacilli. Cheesy matter of any source is a dead substance, and it is usually inhabited by bacilli, if these get access to it; while other bacteria are scarce in this nidus.

Examination of materials from the autopsy table shows that tubercle expresses itself in various manners. Primarily tubercle occurs as a mere infiltration of lymphoid cells in the adventitia of blood-vessels, or as small nodular masses of lymphoid infiltration around blood-vessels or ducts of any kind; or tubercle tissue may organize within blood-vessels and various ducts. Sometimes tubercle appears as a diffuse lymphoid infiltration, extending over a larger area, showing a greater or less tendency towards the formation of nodes and cheesy or fibroid change, as in the lungs. Tubercle tissue may form masses of the size of a hen's egg, particularly in the brain and serous membranes.

In the lungs, in racemose glands, and in mucous membranes, catarrhal changes always follow the tubercle infiltration. On serous surfaces primary tubercles appear often as flat or nodulated patches of various sizes (in peritoneum), or as fungoid vegetations (in synovial cavities), or even as large plastic masses (in omentum). In the skin and mucous membranes, tubercles produce eruptions, ulcers, or nodular indurations; in bones—caries, with abscess formation in surrounding parts (cold abscesses). Fibroid capsules, made up of connective tissue, due to reactive inflammation, enclose often smaller or larger tubercular masses, especially if these have undergone cheesy change.

Primary tubercle manifests itself quite variously in different animals. In guinea-pigs and rabbits, it appears mainly as small cellular infiltrates; in dogs, it often undergoes a fibroid change; in goats, and especially in cattle, tubercle often forms large nodular, sometimes pedunculated masses which often calcify;* in birds it forms, preferably in the liver, large round mulberry masses, which, on section, appear sometimes as horny radiating structures.

Secondary tubercle presents an aspect entirely different from primary tubercle, and it manifests itself in nearly all instances in but one form, namely, as a fine miliary eruption representing those well-known gray, semi-transparent nodules, of the size of a millet-seed, called miliary tubercles. These seem to lie in the perivascular lymph-spaces, and are probably distributed throughout the body mainly by means of these lymph-channels of the blood-vessel walls. Tubercles do not occur in avascular tissues. There is, however, a second form of embolic or metastatic tuberculosis which evidently distributes itself by the blood-current proper, and it appears in the form of conical masses or round nodes which may reach the size of a walnut and are located usually at the bifurcation of arteries. No mention of this form of tubercle is made in text-books, although upon the post-mortem table this variety of tubercle is a very common occurrence. Especially is

* I have met with, on the autopsy table of the Philadelphia Hospital, two cases of tuberculosis in man that were identical in every respect to bovine tuberculosis. Dr. Creighton, of Cambridge, England, describes a number of cases from his own observation, and collected from literature. *Bovine Tuberculosis*, London, 1881.

it seen in the lung, and, more rarely, in the spleen and liver.

Taking into consideration the enormous frequency of local tubercular lesions (counting pulmonary phthisis in this category), the occurrence of secondary or true miliary tuberculosis must be considered a rare affection. A tuberculosis affecting the lining of even the whole peritoneal cavity, including its lymphatic glands, or that of the pleural sacs, or that involving one or both lungs, must, when occurring thus in but one locality, be considered a local tuberculosis. In such instances, the tubercle spreads by continuity of structure.

It is a fact, established by Virchow, that tuberculosis is at first a local disease, and only becomes generalized secondarily. This generalization does not affect the blood, as in the infectious diseases, but it takes place simply as an embolic process, as in some tumors. Local tuberculosis in external organs and accessible lymph-glands is often a harmless affection. It is strongly related to primary tumors. Complete early removal of local tubercular lesions is practised successfully in Europe. Volkmann and others have removed, for instance, lymphatic glands, testes, and joints affected with fungoid synovitis, with the object of preventing secondary tuberculosis, and have thus prevented a general miliary tuberculosis.

Nor should a gloomy prognosis be given in early phthisis. It is astonishing what a large number of healed cavities and cicatrices in the apices of lungs are found on the post-mortem table, indicating the healing of phthisis in persons who long subsequently died from some other causes in later life.

We have seen that tuberculosis manifests itself quite differently as to structure, appearance, distribution, and determination, in the various animals, and even differently in the various organs of one individual. Our studies have shown that these variations in the expression of tuberculosis depend upon the structural peculiarities of the various kinds of animals, and sometimes even upon the difference of the structure in animals of the same species.

We have also seen that even in human beings tubercle tissue may manifest itself in various forms. In some individuals it develops rapidly, and spreads over large

areas, becoming generalized and undergoing speedy cheesy change; in other individuals it develops slowly, fibroid change predominating; and in others the tuberculous product may calcify. In most individuals tubercular lesions may remain entirely local.

It is well known from clinical experience that the general condition of the organism has very much to do with the healing of a local tuberculosis. A local tuberculous inflammation may heal or become arrested in its progress, if the patient "gets strong," or it becomes more developed and aggravated if his general health "runs down." Observation has further shown that any simple, non-specific wound in a weak, ill-nourished individual may fail to heal, becoming unamenable to treatment, and probably assuming a tubercular character.

In some animals spontaneous tuberculosis is unknown, and while some animals are easily tuberculizable experimentally, in others tuberculosis cannot be produced.

It is in accordance with experience that in a large number of families the predisposition to tuberculosis is hereditary, and that their members die promptly of phthisis at a certain age from the effects of a simple "cold," while in the history of other families this affection is unknown. Every individual is liable to acquire syphilis, smallpox, and other contagious diseases, but it is proven that not every one can have tuberculosis. A special predisposition and a special individual are required. In such an individual, a simple inflammation resulting from any cause whatever can produce tuberculosis.

Therefore, for the development of tuberculosis two conditions are necessary:

1. A *definite* soil.
2. An *indefinite* irritant.

The reaction of the soil is always the same under the influence of any irritant, whether that irritant be a bacillus or not; since the result (tuberculosis) following a lesion in such a soil depends upon the character of the soil, and not upon the character of the irritant, even though one irritant, say bacilli, may act more readily than other irritants.

In view of the demonstrated fact that simple injuries of any kind can excite a tuberculosis, but only in certain individuals and tissues, it is evident that tubercu-

lization is determined by the kind of soil, and not by a specific irritant. *Tubercle should therefore be defined as being an inflammatory new formation in a specific individual or tissue.*

What is the place for tubercle in pathology? The anatomical criterion for tubercle is a granulation tissue made up of lymphoid or epitheloid cells, which, on account of deficiencies in the soil, does not undergo any higher organization or tend to heal, but tends to form nodes and undergo cheesy change. Under favorable circumstances it may heal through fibroid change. The elements of tubercle tissue may spread by continuity of structure to surrounding parts, and occasionally tend to the production of metastasis, distributing themselves by means of the lymphatic system principally, and rarely by blood-vessels; and may generalize themselves through the whole body, forming miliary nodes or tubercles.

This miliary eruption of tubercle appears to have the same relation to the primary tubercular growth as the secondary metastatic cancer eruption has to the primary cancerous growth. Like in cancer, the elements of tuberculosis may be arrested temporarily by the lymphatic glands governing the affected region.

In tuberculosis lymphoid cells form the nodes; in cancer, epithelial cells. While secondary cancer nodes are, as a rule, much larger than tubercular nodules, on account of the well-known great proliferating power of epithelium, it is also a fact that cancer may appear as a miliary carcinoma, expressed by minute nodules not distinguishable macroscopically from miliary tuberculosis. Cancer is proven to be a local disease. It is not contagious. It is infectious only to the individual who is affected by it; *i.e.*, it is self-infectious. And so is tubercle in every respect, a local, self-infectious disease.*

That local manifestation of tuberculosis

in the lung which is designated by the traditional name of pulmonary phthisis forms perhaps nine-tenths of all tubercular lesions, and hence deserves some special consideration.

I class myself with those who regard all forms of pulmonary phthisis as tubercular. There are only three or four lesions of chronic wasting disease of the lung which may be excluded from phthisis. These are atelectasis, or collapse from pressure of effusions; bronchiectasis, in which the enormous dilatation of the bronchi may lead to large cavities and atrophy of lung-structure; primary fibroid changes; and abscess of lung. Yet all these lesions may become tuberculous from secondary inflammatory changes, which usually follow.

The lesions that are known as catarrhal pneumonia, broncho-pneumonia, pneumonic phthisis, cheesy pneumonia, tubercular phthisis, and fibroid phthisis are all manifestations of the one disease. Such a classification may be, however, entirely justifiable and useful for practical clinical and therapeutic purposes. Pathologically considered, phthisis is a local tuberculous inflammation of the lung which may manifest itself in various ways, the appearances depending upon the duration of the disease, the mode of onset, and the constitution and condition of the patient. Lesions representing the different forms of phthisis, and their transition from one form to the other, are often seen in the same lung.

Virchow insists that nothing should be considered tubercular unless it shows true tubercle nodules, and hence he does not recognize cheesy pneumonia—or cheesy hepatization, as he calls it—as tubercular, although he does not object to the term phthisis for this lesion.

I was fortunate enough to attend several times the classical demonstrations on this point of Virchow, the father of the view of the dual origin of cheesy matter and phthisis; yet, from our present knowledge of what constitutes tubercle, I cannot help interpreting all the forms of phthisis as of a unitarian origin. It is, after all, as Virchow himself says, only a matter of nomenclature. If we consider the presence of bacilli of Koch as the differentiating point between what is tubercular and what is not, we find that catarrhal and cheesy pneumonias are the most tubercular of all,

* Cancer and tubercle are considered analogous lesions and classed with tumors by a number of pathologists. This fact would not make it inconsistent to call tubercle an inflammatory product, as the distinction between inflammatory processes and tumor-formation is a purely arbitrary one. Virchow pointed out that the majority of tumors are purely inflammatory products (a statement antedated twenty years by Prof. S. D. Gross). A few years ago I made the question of the etiology of tumors a subject of careful personal study, which I yet continue, and I am forced to the conclusion that *all* true tumors are inflammatory products, and that no line of distinction can be drawn where the process which we call inflammation ends and where tumor-formation begins. (The Etiology of Tumors. Transactions of the Pathol. Soc. of Phila., 1881.)

because they contain, as a rule, more bacilli than any other form of phthisis.

Although cheesy pneumonia, like all forms of phthisis, remains commonly a local affection, it is seen on the autopsy-table to give rise to miliary tuberculosis at least as often as any of the other forms of local tuberculosis.

We are then at present at the same stand-point in regard to the character of tubercle and cheesy matter as Laennec (1819); and it is indeed perfectly reasonable to suppose that any cheesy matter found in a scrofulous person or animal is tubercular. Of course it is evident that tuberculosis of the lung is usually accompanied by simple inflammatory products, such as organized connective tissue (chronic phthisis), or unorganized croupous and catarrhal exudates (predominating in acute phthisis), which may undergo rapid necrotic and purulent changes, resembling cheesy material. For the latter products the name "coagulation necrosis," as applied by the Heidelberg and Leipsic people, may be employed. Tubercle-bacilli are commonly found in this coagulation necrosis. True tubercular cheesy matter should, I think, be considered only that product which is derived from the breaking down of previously well-organized tubercle tissue.

I need not refer to the details of the manifestation of tubercle in the lung, as these are too well known. But I would like to remark here that those small whitish or gray nodules, usually of somewhat irregular shape, which are seen more or less densely scattered throughout the parenchyma of lungs affected by phthisis, are not miliary tubercles, but minute foci of broncho-pneumonia.*

These minute broncho-pneumonic foci take their origin from tuberculous matter disseminated by means of air-passages, as explained before. *Miliary* tuberculosis of the lung distributes itself by means of the perivascular lymphatics, is very rarely accompanied by catarrhal changes or hepatization, and rarely arises from a primary tuberculous focus of the lung itself; it is, as a rule, a part of general tubercular disease.

(To be continued.)

* See, in connection with this, the excellent studies of William H. Mercur, from the pathological laboratory of the University of Pennsylvania, published only in abstract form in the *Phila. Med. Times*, July, 1883.

RUPTURE OF THE UTERUS DURING LABOR, WITH AUTOPSY.

BY C. W. DE LANNOY, M.D.,

Chester, Pennsylvania.

THROUGH the kindness of my friend and colleague Dr. J. L. Forwood, I assisted at the following autopsy, and obtained the history of this interesting case.

Mrs. X., an Irishwoman, about 43 years of age, who had been previously delivered without trouble of several healthy children, sent for him to attend her in labor. When he reached her house the labor had been in progress several hours, and at the time firm and periodical contractions indicated that the uterus was normally active and promised speedy expulsion of its contents. A digital examination, which was made immediately, revealed a breech presentation, with only partial dilatation of the os. No pressing interference being deemed necessary, the patient was made as comfortable as possible, and, under the continuance of active uterine contractions, dilatation of the neck was waited for. At the end of four hours from the beginning of labor the os seemed to be sufficiently open to admit the presenting part, but the latter had not as yet engaged in the superior strait. Suddenly, on the occurrence of a pain, the face of the woman assumed an anxious expression, the countenance indicating impending dissolution, and as the hand was passed into the vagina a foot was felt to recede, as if drawn up by powerful suction. No external hemorrhage took place, and, although periodical uterine or possibly purely abdominal contractions continued, she perished within half an hour after the accident.

Autopsy.—The body was that of an unusually fleshy woman, with an enormously tumid abdomen. Percussion elicited a marked impression of solidity, but afforded no signs of a double pregnancy; the greatest abdominal diameter was from side to side, and the protrusion of the lateral regions was extraordinary. Making the prescribed crucial incisions, we found the abdominal walls unduly thin, and devoid of adipose, so abundant elsewhere. The child, with its back to the front and head to the right, occupied the entire transverse diameter of the abdomen (see Fig. 1), the left posterior axillary terminus falling beneath the umbilicus of the mother; the right side of the foetal head and back were covered by the

omentum, and the buttocks were thrust into the upper part of the left maternal groin. Below the foetus, and between it and the symphysis pubis, was the placenta, occupying a central position, with its maternal surface in contact with the parietal peritoneum. The umbilical cord was visible between the left ear of the foetus and the upper placental margin. After taking the sketch (Fig. 1), we removed the pla-

were normal, with a slightly exaggerated sacral prominence.

It must be assumed in this case that rupture of the cervico-uterine walls was the result of combined causes. The foetus was extremely large, and must have weighed fourteen or fifteen pounds; it had evidently expired some days previous to the onset of labor; at least the advanced stage of putrefaction in which we found it could not be

FIG. 1.

Position of foetus and placenta after rupture of the uterus.

FIG. 2.

Peritoneal laceration. Case of rupture of the uterus.

centa and foetus, throwing up the omentum and transverse colon, which partially covered the latter. The concave foetal surface of the placenta fitted like a cap over the fundus of the womb, which was in a position of extreme ante flexion and slightly inclined to the right; then, dragging the buttocks of the child from the left iliac fossa, we found the feet still buried in the large peritoneal laceration represented (Fig. 2). The small intestines were all crowded up into the right hypochondrium, apparently retained there by the foetal head; they contained little or no gas, far less than is ordinarily met with in average autopsies. The abdomen contained about one quart of blood, with but few clots, of small size. The pelvic diameters

otherwise accounted for. We might reason from the above premises that a large, dense mass, exercising great pressure upon a disproportionately thin-walled cavity, would alone exert influences tending towards rupture; but when, in addition, we have the evil effects of putrefaction, which would bring about softening of the mucous membrane and muscular fibre of the womb, the probabilities of so serious an accident would become imminent. The transverse position of the foetus would lead one to infer that it had escaped into the peritoneal cavity head-foremost; and such was my opinion previous to consideration of the facts incident to her labor. The breech presented at the mouth of the womb, and a foot was felt in the vagina

immediately after rupture was supposed to have taken place. The rent in the walls of the womb was situated at the junction of neck and body, involving both of these parts. The foetal head at the time of rupture still occupied the fundus of the womb, and could not have found egress through an opening situated low down at the brim of the pelvis. It will be further noticed, by referring to Fig. 2, that while it is in the course of nature for the uterus to contract down after voidance of its contents, per vaginam or otherwise, we have in this case an unusually marked disproportion between the sizes of foetus and contracted uterine tissue. The inference is that, like the abdominal parietes, the uterine walls were unusually thin, and, although the peritoneal rent seems small, it was no doubt a large one before its outline had narrowed down in obedience to uterine contraction. Further, the position of the foetus in its extra-uterine habitat may have been influenced, determined, or even radically changed by the periodical contractions of the abdominal muscles subsequent to the rupture: this latter phenomenon was maintained for half an hour, the time which elapsed between the supposed occurrence of rupture and a fatal issue.

To sum up the etiological value of both clinical history and post-mortem appearances, it would seem that in this case the obstacles opposing the escape of the foetus from the cavity of the uterus were, first, the walls of that cavity, and, in the second place, the ordinary resistance of the uterine neck previous to complete dilatation; of the two the former proved least difficult to overcome, and hence delivery by other than *per vias naturales*.

HOT WATER—AN OLD REMEDY REVIVED.

BY W. THORNTON PARKER, M.D.

SO much attention has been given of late to the use of hot water as a remedy of the first importance in many diseases that I believe a few remarks on this subject may be advisable.

The number of diseases and of injuries which can be successfully treated with hot water is very much greater than most people seem to be aware of. I have under observation at present some very interesting cases where the treatment by hot water

seems to be succeeding remarkably well. I refer to the internal or "therapeutic" use of hot water. There is, of course, great difference between using this remedy after the manner recommended by Dr. Salisbury and taking a gobletful occasionally. The use of hot water as a remedy in serious disorders must be employed systematically and perseveringly.

After severe mental or bodily labor, where a sense of exhaustion is experienced, the use of hot water is likely to afford an immediate sensation of relief, increased strength, and even exhilaration. Unlike the effects of alcoholic stimulants, this improvement continues for a long time; the appetite is stimulated, a general improvement actually taking place. The use of hot water immediately before meals is not the course recommended by Salisbury, although it is undoubtedly desirable for many and does act as a tonic of no little value. It is well known that in early colonial times, and indeed until quite recently, the custom of serving at meals hot water for "sipping" was quite general and very highly approved of in our best society. It is not improbable that, in view of the high authorities recommending hot water, and the very remarkable cures attending its use at the present time, we may have a revival of this time-honored custom.

Nearly fifty years ago there appeared in England a collection of essays, by Thomas Walker, M.A., called "The Original." In 1875, Dr. Guy published a revised edition of "Walker's Original,"* and from "The Arts of Life," part ii. page 94, I will quote from Walker's essay on "Hot Water," and Dr. Guy's note on the same:

"Having said much about wine, I will not omit all praise of hot water, the efficacy of which on many occasions in life is very great and cannot be too generally known. I will begin with a remarkable cure effected by it on myself. Many years ago, when I was laboring under what I supposed to be an attack of common sore throat, I rode some miles on horseback, with a north wind in my face. I then got into the mail, and travelled nearly two hundred miles, and at the end of my journey I could scarcely speak or swallow. In the morning I was still worse, and on attempting to force down a little coffee I

* The Original. Fifth Edition. Dr. Guy. London: Henry Renshaw.

found it utterly impossible. In this extremity, a physician, now among the most eminent of his profession, called upon me, partly through accident. He told me I had got a very bad quinsy, and he immediately ordered a kettle of hot water, recommending me, to gargle with it as hot as I could bear, and continually. As we were on intimate terms, and he was then only commencing practice, he remained with me two or three hours to enforce his prescription. I found so much benefit that after he was gone I persevered till night, at which time I was enabled to take food without difficulty, and in the morning there was no trace whatever of the attack, nor have I ever experienced another, though I was told it would most probably be the case. The medicine ordered me I did not taste, and the sole glory of my rapid and complete cure is due to the hot water. I have never had even a common sore throat since, or I should certainly try the same remedy, though I never heard of its being so applied."

Dr. Guy's note is as follows: "This is a good example of the fallacy of many popular opinions on medical matters. From the author's description of his attack, it is obvious that the quinsy had arrived at that stage at which the only possible relief is by a discharge of matter. Hot water could have no curative effect in such a case; but, through a happy coincidence, art earned the credit due to nature."

This statement by Walker, made so long ago, although severely rebuked by such eminent authority as Prof. Guy, is, after all, correct in practice. I have repeatedly treated cases of quinsy, entirely depending on hot water from first to last. I would recommend the use of hot water not only as a gargle, but taken in the manner recommended by Dr. J. H. Salisbury and Dr. Ephraim Cutter, which I will refer to again before closing this article. During the past summer three cases were treated successfully by this method, and I am sure would generally be found successful. Walker also recommends hot water in bruises, which he considered "most efficacious, both by means of immersion and fomentation, in removing pain and totally preventing discoloration and stiffness. It has the same effect after a blow. It should be applied as quickly as possible, and as hot as can be borne." He also recommends immersion in hot water for the fin-

ger suffering with whitlow, and this is certainly good treatment to-day. Where the fingers have been crushed in shutting a drawer or a door, he considers hot-water treatment better than anything else. "*The efficacy of hot water in preventing the ill effects of fatigue is too well known to require notice.*" In the *Lancet* for November 24, 1883, Dr. Jackson reports some cases of gout and gravel relieved by using hot water as recommended by Cutter in the *Lancet* of September 15, 1883.*

It is, however, in phthisis that the hot-water treatment exhibits its remarkable value, and Salisbury's treatment must sooner or later win the good reputation it certainly deserves. In the treatment of dyspepsia and of constipation it has already won considerable fame. Its uses in gynecology are too well known to need any quotation, and Prof. Hamilton has employed it with excellent success in surgery.

Prof. Hamilton remarks,† "No treatment hitherto adopted under our observation has been attended with equally favorable results." It is hot water, and not warm water, which is recommended, of a temperature from 110° upwards to 150° Fahrenheit,—one or two gobletfuls, taken *gradually*, one hour or longer before meals; although half a gobletful may be taken directly before eating, by "sipping," as in the old fashion referred to. It is a very good plan to take hot water before going to bed, also after a long ride or walk and before bathing. Within ten days after commencing the hot-water treatment the good effects are noticed by the improvement in the general condition of the patient. "The sweat starts freely after drinking, giving a true bath from centre of body to periphery." "The skin becomes healthy in feel and looks." "The digestion is correspondingly improved, and with this improvement comes a better working of the machine."‡

Dr. Cutter makes the following claims for the hot-water treatment:

"(a) Foundation for all treatment of chronic diseases.

"(b) Excites downward peristalsis.

"(c) Relieves spasm or colic of the bowels by applying the relaxing influence of heat inside the alimentary canal.

* I can also recommend it highly in cystitis, gonorrhœa, and prostatitis.—W. T. P.

† Quoted by Bartholow, *Mat. Med.*, 4th edit., p. 66, et seq.

‡ The Therapeutical Drinking of Hot Water. Dr. Ephraim Cutter.

"(d) Dilutes the ropy secretions of the whole body, and renders them less adhesive, sticky, and tenacious.

"(f) Dissolves the abnormal crystalline substances that may be in the blood and urine.

"(h) Use it to wash down the bile, slime, yeast, and waste, and have stomach fresh and clean for eating.

"(l) Promotes elimination everywhere."

Dr. Cutter strongly sustains the Salisbury theory of practice with hot water, and, without accepting all the claims made for this excellent old remedy, it must certainly be acknowledged that it has many advocates in this and other countries, and is a very popular as well as a very reliable therapeutic agent, and it also has the advantage of being very accessible and inexpensive. "There is nothing new under the sun!"

Certainly, it is no news to inform the medical profession that the debris and other contents of the stomach and bowels may be washed away and digestion facilitated by the use of copious draughts of hot water. It should be remembered, also, that serious injury may be done the mucous membrane and the secretory organs by a reckless use of this remedy.

Like all other therapeutics, the supervision of a medical man is needed, and without counsel no one should adopt this new treatment. As with many other excellent remedies, there is danger that too much may be attempted, and, from the inevitable injury resulting, a verdict of failure be given for the whole plan.

MOORESTOWN, N.J., December, 1883.

REMARKS UPON NIGHTMARE.

BY GEORGE HAMILTON, M.D.

FOR the first time within the recollection of the writer, an article upon this affection, or rather upon a complication of it with epileptic symptoms, appeared in one of our medical journals,—from the pen of Prof. H. C. Wood, in the *Medical Times* of December 1, 1883. In this paper Dr. Wood declares that "nightmare, as it usually occurs, is not of much moment;" and, so far as relates to the infrequency of a fatal issue, this is true, and hence, in part, the neglect to which it seems doomed by medical writers and lecturers. But may we not greatly err in regard to its fatality?

Of the numerous instances where persons, apparently in good health, retire to rest at night, and yet are found dead in the morning, how many of them, or how few, have succumbed to attacks of nightmare, it is wellnigh impossible to determine. The almost invariable custom, in such cases, is to give a certificate or render a verdict of apoplexy or disease of the heart,—whether there has been an examination of the cadaver or not. Now, it is generally admitted that, whatever may be the exciting or the proximate cause of nightmare, it is the vascular system, and notably the heart and brain, that are most involved in this affection, so that in this malady a post-mortem would probably exhibit appearances not very dissimilar.

As a case, in illustration, formed the basis of the paper of Prof. Wood, so in the present instance his example will be followed; it is not the purpose of the writer to treat of the subject generally, for with the usual phenomena of nightmare a large proportion of people are more or less familiar. The case to which allusion will now be made is, in the writer's experience, an exceptional one, if not in character, at least in severity, and is as follows:

A gentleman, far beyond middle age, had been in the earlier part of his life subject to repeated attacks of nightmare in its ordinary form, caused, as usual, by dreams of a terrifying character,—such as falling from elevated positions, attacks of wild beasts or savage dogs, or being waylaid in solitary places by men bent upon robbery or murder, etc. Not infrequently he would find himself in a vast amphitheatre,—the Colosseum, for instance,—witnessing the furious combats of gladiators or wild beasts, or the desperate struggles of men and horses for victory in the chariot-races,—during which, especially at the moment of victory, the shouts of tens of thousands would break forth with such astounding, unearthly violence that the terror of our subject, already beyond conception, would reach its ultimatum by the crashing down of the vast structure, burying everything beneath, and accompanied with a noise so fearful that all creation seemed rushing into general ruin. Scenes of this peculiar kind were to him far more frightful than those produced by ordinary agencies. The oppression of the chest and attendant sense of suffocation, usually felt, were nearly absent in this case, and he was, as often happens, unable to cry out or utter a word during the fit, but the moment this was over he regained the power of speech and the use of his limbs. Attacks of this sort, recurring at longer or

shorter intervals, continued up to his twentieth year, and did not return, unless at very remote intervals, till about his sixtieth year. From this period on, through many years, the attacks would not be ushered in from terror of wild beasts pursuing him, or from falling from great heights, etc., but would nearly always occur through the agency of human beings. He would hear one or more persons trying to enter his residence, or, having gained entrance, endeavoring stealthily, almost noiselessly, to gain admission to his chamber; or, more alarming yet, would perceive that they had already entered the room and were cautiously approaching his bed. In these attacks, as in those of earlier years, he suffered very little from oppression or sense of suffocation, and it was only after several years that he was able to utter a word even imperfectly, or cry out, and this noise would in some cases serve to awaken him; but generally he could only be aroused by the persistent efforts of his wife in endeavoring to change his posture, or calling aloud to him. But here we have the great distinction between the phenomena of his early life and those of his advanced years, for, as above stated, the moment the attack of his youth was over he could at once converse as well as ever, and assume whatever position or posture he preferred. On the contrary, in very many of the attacks of his later years, and this, too, even after being aroused from sleep, and conscious, too, of whatever was said or done, he would nearly always remain for a short time passive, having no power to move his limbs, nor could he speak so as to be understood for a much longer time, lasting on some occasions more than half an hour, and whilst in this condition his speech was precisely similar to that of paralysis, which, in fact, for the time being it was. In this connection it must be stated, as an important factor in reference to the pathology of the case, that, as a rule, so soon as he awoke he noticed that a more or less partial erection existed, without the slightest thought, however, or feeling of sensual character.

Prof. Wood refers in his paper to his paralyzed condition, and the horrible suffering, so intense in fact that although lasting but a few seconds it was conceived to be of almost infinite duration. This feature, then, in the single experience of Dr. Wood, is but the counterpart of what occurred in many of the attacks endured by the patient now presented. In fact, when asked to define the nature of this suffering, he would reply, "That is impossible," adding, "that all the terrors of his early experience could not be compared with the suffering of the later attacks;" and yet he was not conscious of physical pain of any sort, nor, as

said before, of oppression or sense of suffocation. Of fright or fear of death he had no thought, for the suffering, although indescribable as to character, was so inconceivably intense that instant relief was the only thing thought of, if indeed any rational conception at the moment were possible.

To endeavor to explain the extraordinary vagaries of nightmare, in reference to its physical causation, would be to attempt the impossible, whilst it is not beyond our province to seek an explanation of the phenomena just stated to certain pathological conditions. The generally accepted opinion that persons having enlargement of the heart or valvular affection are more disposed to nightmare than others is probably well founded. That such persons are subject to congestion of the heart, of passive character, must be admitted; and it is not unlikely that a large proportion of such cases as usually occur are due to this cause. But attacks complicated with paralysis cannot be thus explained; and as congestion of the heart cannot long continue without implicating the brain and upper portion of the spinal marrow in a similar way, the occurrence of the paralysis may thus be explained. It is well known that erection, complete or partial, has often been observed in case of execution by hanging, and here congestion must of necessity take place, and this incident would seem to show a relationship with what occurred in the individual referred to above.

In regard to the exciting causes of nightmare, irregularity and excesses in eating, drinking, or sensual indulgence, are, doubtless, deservedly placed among the more prominent. A rich, abundant, and late supper has justly been regarded as the cause of many attacks; but the patient referred to informed the writer that if he retired to rest with a void sensation from want of food he was much more likely to have an attack than if he had previously eaten a moderate portion of rather rich food; and this is unquestionably the fact in general experience. Mental agitation, even joyous, if in excess, depression or worry from any cause, are well-known agents in the production of this affection. For the prevention of nightmare many were the proposed remedies, material or magical, of the olden times; and whilst medicines of anodyne or antispasmodic nature have sometimes

appeared to forestall these attacks, it is now generally admitted that the avoidance of all noxious agents, temperance in the manner of living, and, so far as possible, control of the intellectual, moral, and emotional nature, will prove the most useful in guarding against attacks of this most frightful and, as it may well be feared, too often fatal malady.

1600 SUMMER STREET, PHILADELPHIA.

REPORT ON LARYNGOLOGY AND DISEASES OF THE NOSE.

BY DR. CARL SEILER,

Instructor in Laryngology at the University of Pennsylvania,
Lecturer on Diseases of the Throat and Nose in the University Post-Graduate Course, etc.

CYSTIC POLYPI IN THE UPPER AIR-PASSAGES.

IN a late number of the *Medical News* an article appeared by Dr. Lefferts on a case of cystic tumor situated in the posterior nasal chamber, which was not recognized as such by him at the rhinoscopic examination, and he was only made aware of the nature of the growth by the copious discharge of serum and the small amount of tissue brought away by the forceps. These cases are very rare, and besides the one recorded by Dr. Lefferts one other case only is reported in the literature on the subject. It has, however, been my good fortune to meet with four such cases, and in the second edition of my book I mention the existence of these cystic polypi. The last case I saw was interesting from the fact that the patient had previously suffered from fibrous polypi, and I will therefore give a condensed history of her case.

Mary H., a native of Virginia, presented herself two years ago at the dispensary for treatment. She said that, a year previously, her physician at home had removed several pieces of a tumor from her post-nasal cavity, but she had not been able to breathe freely through her nose after the operation, and that now she could not draw any air through the organ. On examination with the rhinoscope and with the fingers, I discovered a very large fibrous polypus filling the naso-pharyngeal cavity and extending into the right anterior nasal cavity, filling it completely. After several unsuccessful attempts I succeeded in getting a wire loop around the growth and removing it in its entirety. An examination after its removal showed the polypus

to have been attached to the posterior edge of the vomer. The patient was kept under observation for several months, and as there was no return of the growth she was dismissed as cured. A few weeks ago she again presented herself, saying the tumor had come back. On examination I saw a large polypus filling the right nostril, apparently springing from the posterior portion of the middle turbinated bone. The wire snare was introduced, but repeatedly slipped off, and, getting impatient, I resorted to the forceps. A very slight pull brought a large quantity of yellowish serum, which gushed out of the nostril. This made me aware of the nature of the growth, and, after removing the forceps, I saw, in the rhinoscopic mirror, the sac hanging from the middle turbinated bone. This was easily removed with the forceps, and after the hemorrhage had ceased and the parts had been washed I discovered quite a large polypus springing from the upper portion of the nasal cavity. This was easily engaged in the snare and removed, and proved on examination to be a fibrous polypus, the lower portion of which had undergone cystic change; there being a cyst the size of a small cherry.

IMPROVEMENTS IN LARYNGOSCOPIC APPLIANCES.

Among the improvements in instruments for the treatment of nasal diseases must be mentioned two changes made in the wire-snare originally introduced by Dr. Jarvis, of New York. One is the application of the instrument to the requirements of galvano-cautery by substituting platinum wire for the steel wire, and suitable attachments for the battery, by Dr. Jarvis himself; and a change made by Dr. Sajous, of this city, which consists in the substitution of a slender rod with an eye at the end for the long wire, which enables the operator to use small pieces of wire to form the loop and saves the trouble of fastening the ends. The instrument, however, loses thereby much of its lightness and delicacy, and it is a question whether the change is an improvement.

The last number of the *Archives of Laryngology* is replete with interesting articles, among which the one by Dr. French, of Brooklyn, on "Photographing the Laryngeal Image," is of peculiar interest, on account of the progress which he has made

in this difficult procedure. Ever since the laryngoscope has been in use a number of experimenters have attempted to reproduce the laryngeal image by means of photography, in order to obtain a picture which should be more satisfactory than a drawing, and should come nearer the truth than the conventional pictures seen in books on the subject. But none have attained the desired end except Dr. French and Dr. Lenox Browne, of London, who recently sent some excellent photographs of the living larynx to this country. But good as they are and true to nature, they also present the same outline as the drawings and lack the depth and perspective which make the image seen in the mirror so much more satisfactory. And I do not think it is possible to reproduce this perspective, except, perhaps, by making a stereoscopic picture and viewing it through a stereoscope, for only then can we expect to obtain a reproduction of the roundness and reality of the image. However, Dr. French and Dr. Browne have given us pictures which far surpass even the fondest hopes of the earlier experimenters, myself included, and open up a possibility that photography may become an important aid in the art of laryngoscopy.

As a curiosity in the literature of laryngology the following abstract from the *Therapeutic Gazette* deserves to be mentioned. Dr. Th. Dimmock, of New York, under the heading "A Novel Laryngoscope," gives the following directions for seeing the larynx without a mirror:

"Bring the patient near a good light of any kind, and after the mouth has been opened, place on the tongue a depressor; then request the patient to yawn. The larynx will immediately rise, and every part *necessary to be seen* will be brought fully into view." Quod erat demonstrandum. Had we not better throw our costly and cumbersome instruments away and, armed only with a tongue-depressor, go forth and study laryngoscopy? What a pity Dr. Dimmock did not precede Garcia and Czermak with his discovery! But perhaps what he thinks is necessary to be seen is only the tip of the epiglottis, and we had better pause in our mad career and retain the mirrors and other appliances so as to look a little lower down into the laryngeal cavity proper. It is true there are a

number of cases in which the epiglottis is erect, and its upper portion can readily be seen by depressing the tongue, especially when gagging sets in, but very little is gained from such a view, and intra-laryngeal disease cannot be diagnosticated nor treated without the laryngeal mirror.

TREATMENT OF TONSILLITIS.

The treatment of tonsillitis has of late been largely ventilated in the medical journals of this country and also in those abroad, and various remedies have been praised as specifics in this painful, and often recurrent, throat affection. Thus, for instance, a correspondent of the *Medical News* treats tonsillitis by the application of bicarbonate of soda, and claims that seldom are more than three applications of the dry drug necessary to cure even severe cases. There is no doubt that a mild alkali, such as the bicarbonate of sodium, is very soothing when applied to inflamed surfaces, and it is used largely in the treatment of burns on the skin, but in my experience it has failed to be more than a soothing application, and in spite of it many cases go on to suppuration. The same is true of the application of the gum-resins so highly recommended some time ago in this affection. I have not found anything better than a strong solution of nitrate of silver, sixty to one hundred and twenty grains to the ounce, applied with a brush to the inflamed glands; and, if the remedy is resorted to early in the disease, the symptoms almost invariably subside within a few hours. If, however, the inflammation has lasted for a day or two, the silver-solution will not abort the attack, but it will in most instances prevent suppuration. It is curious to observe with what regularity in some persons the tonsillitis recurs during the winter months, and I have seen a number of cases in which a tonsillitis occurred regularly every six weeks. In these instances it is best to remove the glands, which are always more or less hypertrophied after an attack has passed off, either with the tonsillotome or, if the gland be too small to be grasped by the annular knife of the instrument, by a few incisions with the galvano-cautery knife.

It is a gratifying result of the investigations of earnest workers in laryngology that very little is nowadays said or written about pharyngitis in its various phases.

This affection but a few years ago was looked upon by the practitioner as the ready explanation of almost all throat troubles, and was accordingly treated vigorously with probang and brush; while now it is known to be in most instances merely a symptom either of nasal catarrh or of gastric irritation, and will disappear with the removal of the cause without any direct local treatment.

In conclusion, I will briefly relate a case which illustrates the above remarks in a striking manner. A young lady came to me to be treated for a constant dryness and tickling in the throat, which had lasted for several years and had resisted the vigorous treatment with the whole list of astringents applied to the pharyngeal wall. An examination revealed the pharynx to be studded with enlarged follicles, which were red and irritated. The larynx was normal; but in the naso-pharyngeal cavity I discovered two very large posterior hypertrophies, springing from the posterior ends of the middle turbinated bone on either side. These I removed in succession with the wire-snare at an interval of a week, and two weeks after the second hypertrophy had been removed the pharynx appeared normal, and all symptoms of the former trouble had disappeared. No applications of any kind had been made during the time of treatment.

1346 SPRUCE STREET.

NOTES OF HOSPITAL PRACTICE.

CLINIC OF LOUIS A. DUHRING, M.D., PROFESSOR OF DISEASES OF THE SKIN IN THE UNIVERSITY OF PENNSYLVANIA.

Reported by HENRY WILE, M.D.

THREE CASES OF SCABIES.

THREE boys of the same family, aged respectively 10, 8, and 6 years, exhibit, in various degrees of intensity, a marked eruption, especially on the hands, arms, neck, abdomen, genitals, and buttocks. The duration of the disease has been from eight to ten weeks, and the eminent characteristic of the lesions is their multiformity. They consist of points, papules, vesico-papules, and here and there a pustule. In addition to these are excoriations, and crusts. In this disease lesions soon occupy very nearly the whole surface of the body, with a predilection for certain regions as the interdigital spaces, the

flexor surfaces of the arms, the penis of the male, the breasts of the female, and the buttocks. Their multiformity and distribution give the key to the diagnosis, and we have here three cases of scabies, or itch. Itching is a constant symptom, being especially annoying at night when the patient is in bed. The disease is eminently contagious, and is produced by the presence of the itch mite, called *sarcoptes scabiei*, an animal parasite. It moves between the layers of the epidermis and in the rete Malpighii, feeding upon the juices of the skin, and as it moves along it lays its eggs, and after a short time the characteristic burrow is produced. In these cases we have any number of such well-marked burrows. They vary from a line to a quarter-inch in length, being often discolored by foreign matter gaining entrance or being rubbed in, and at the end of the burrow is a point representing the seat of the mite. Scabies is comparatively rare in Philadelphia, but is more common in seaport towns. The treatment is at once simple and satisfactory, consisting in the use of some parasiticide, and among the best are the sulphur preparations. Here we will direct the following:

R Sulphur. præcipitat.,
Balsam. Peruviani, aa ʒi;
Adipis, ʒi.

M. Ft. ungt.

Sig.—To be well rubbed into the entire surface of the body twice daily.

ALOPECIA AREATA.

A married woman, 33 years of age, presents on the scalp an anomalous condition in various stages of development. About two years ago, according to the statement of the patient, twenty-two bald patches suddenly made their appearance, which is evidence that the disease came on insidiously and had existed some time before it was recognized. At present there are smooth, entirely bald patches, varying in size from a dime to a silver dollar, scattered over the scalp, also some patches covered with a growth of fine whitish silky lanugo, with here and there a scant amount of short black hair, which is all that remains of the original growth. The affection as it here exists is disfiguring, but it is already on the road to recovery, and in several months or a year the hairs will probably all return in their full vigor.

In some cases, however, the disease may continue five, ten, or twenty years, going through various changes, full recovery never taking place. As regards the prognosis, the older the patient the less favorable it is, and the younger the person the more favorable. It very seldom happens that the hair does not return in young persons. The prognosis should, however, always be guarded. It is a disease of the hairy system, affecting not only that of the scalp, but also that of the eyebrows and eyelashes and other parts of the body. It is produced by faulty nutrition and insufficient nerve-force. Some authorities assert that it is of parasitic origin; but the microscope shows no specific fungus. It belongs to the same class of diseases as vitiligo (in which there is an abnormality regarding the deposit of pigment), and often follows mental strain or shock. Internal treatment alone is followed by beneficial results, and arsenic is the agent that cures the majority of cases. It is the only remedy that seems to have a positive effect. Local stimulating applications have no great value,—at least until the hair begins to grow again. The arsenic may be given in the form of arsenious acid, one-fortieth to one-thirtieth of a grain at a dose, using small rather than large doses. Where the hairs are beginning to grow, we may use some stimulating local measures; and in the present case an ointment composed of equal parts of tar and cosmoline will be ordered.

SYPHILODERMA TUBERCULOSUM (OF THE SOLE OF THE FOOT).

A woman, 70 years of age, has a disease affecting the sole of her left foot, and it first appeared about two months ago. At present there is in the centre of the sole of the foot an irregular, palm-sized lesion, consisting of variously sized ulcers, about one-quarter of an inch deep, the surface secreting a yellowish, puriform fluid, and very painful to the touch. Outside of this large lesion are several smaller ulcers scattered about. The whole is somewhat concentric, and possesses all the characteristics of a late tubercular syphiloderm.

These lesions affecting the soles of the feet are difficult to treat, on account of the position. In the first place, the patient will be ordered to bathe the foot in hot water until all the horny epidermis comes

away; then the following ointment will be applied:

R Hydrargyri ammoniati, ʒss;

Adipis, ʒiv;

Cerat. res. co., ʒiv.—M.

Ft. ungt.

Sig.—Apply on small pieces of cloth.

Internally the iodide of potassium will be administered in ten-grain doses three times daily.

HERPES ZOSTER.

A man, about 45 years of age, has a typical acute eruption occupying one-half the body, extending in the shape of a band three inches wide from the spinal column to the umbilicus. The eruption is characterized by groups of vesicles, some smaller, some larger, the average being about the size of a split-pea. Some of the lesions are round, others elongated; some are discrete, while others have coalesced, forming small blebs. The primary lesion is a vesicle surrounded by an inflammatory areola. The color is a pinkish, reddish, bluish tint, and not a bright red.

We have here a typical case of herpes zoster, commonly known as "shingles." It cannot be confounded with any other disease. The eruption of the vesicles is usually preceded by pain or uneasiness in the part, and where there is a persistent unilateral pain this disease may be suspected. The pain varies and is often slight. The eruption is herpetic, in that there are vesicles and that they are grouped. There is no herpes without grouping of the lesions. The eruption is now at its height, and the lesions are already becoming flattened. The contents may be serous, bloody, or pustular, and in severe cases the lesions may leave scars, especially when occurring about the orbit; it may then be accompanied by loss of the eye. The disease may attack any part of the body, but it always occurs in the line of the nerves, and especially along the track of the dorso-abdominalis or dorso-pectoralis. It is generally unilateral, only in very rare cases are both sides of the body affected. As a rule, it attacks an individual once in a lifetime. It runs an acute course in from two to four weeks ordinarily, passing off spontaneously.

The disease is due to an inflammation of the nerves, either the terminal endings or the trunks being affected. The course

of the disease is little influenced by treatment. In some cases the phosphide of zinc, given in pill form, one-fourth to one-tenth of a grain repeated every two or three hours, is of benefit. The best form of treatment, and that which affords the most relief, is with the galvanic current, the negative being passed over the lesions. Locally, powders of lycopodium and starch may be used; but among the best applications are lotions of the fluid extract of *grindelia robusta*, one drachm to the ounce or two of water, or the compound sulphide of zinc lotion, composed as follows:

R Zinci sulphatis,
Potass. sulphuret., āā ʒi;
Glycerin, fʒi;
Aquæ fʒiv.—M.

Sig.—Apply three or four times a day.

A lotion of sulphate of zinc, about five grains to the ounce, may also be used.

ECZEMA PUSTULOSUM.

A boy, 5 years old, of a blond complexion, presents an eruption occupying the entire scalp. It is characterized by bright-yellow, sulphur-colored crusts and the presence here and there of bald patches. The disease has existed six months, and is a typical example of pustular eczema. Occurring on the head and where there is so much crusting as here, it is liable to be confounded with *tinea favosa*, yet the points of differential diagnosis are many and plain. In the first place, the crusts are peculiar to eczema, and bear no resemblance to the characteristic cup-shaped crusts of *favus*; then the bald patches are covered with abundant young hairs and contain no broken-off hairs; then, again, there is an absence of the peculiar mousey odor of *favus*. Besides this, the disease is extending down the sides of the face and on the backs of the ears, and also involves the eyelids.

There is no reason why this disease should prove obstinate, as it is usually amenable to proper treatment, and a cure may be effected in from four to eight weeks. The treatment will first consist of local applications of olive-oil allowed to remain on over-night, and in the morning washed off with hot water and soap. By this means the adherent crusts are readily and effectually removed. After the crusts are completely removed, an ointment of ammoniated mercury, twenty grains to the

ounce of lard, will be applied twice a day, fifteen minutes at a time. Internally, cod-liver oil will be ordered. When we see our patient next week, there will without doubt be a change for the better.

TRANSLATIONS.

SEPTIC PNEUMONIA IN INFANTS.—Dr. Oscar Silbermann draws the following conclusions from an analysis of twelve cases of septic pneumonia occurring in infants:

1. The septic pneumonia of the newborn and infants always originates with a tracheo-bronchitis, and is to be regarded as a catarrhal pneumonia, in many cases due to the presence of a foreign body.

2. It may be produced by inhalation of decomposed amniotic fluid or genital secretions, or through inhalation of infected air in cases of septic infection of the mother.

3. The septic pneumonia of the newborn frequently originates with disease of the pleura, but seldom with disease of other organs, in contradistinction to other septic processes in infants, which are usually associated with multiple points of origin.

4. The alveoli and bronchi of children dying from septic pneumonia are always filled with masses of bacteria.

5. The blood in cases of septic pneumonia in infants shows a great increase in the white corpuscles, with breaking down and solution of the red blood-disks.

6. Jaundice is a constant accompaniment of this disease.

7. The disease usually originates from one to two days after delivery.

8. The disease is always fatal, usually on the third or fourth day after birth.

9. The access of septic material to the lungs in the new-born is favored by insufficient closure of the glottis, and by the shortness of the main bronchi.

10. The wide distribution of the septic process in the lungs is due to active epithelial desquamation and the narrowness of the finest bronchi, as well as the feeble muscular apparatus of the respiratory organs of the new-born child.—*Deutsches Arch. f. Klin. Med.*, December 12, 1883. s.

ENTERITIS IN HEREDITARY SYPHILIS.—Mracek describes the anatomical alteration of the intestine which he observed in six

cases of hereditary syphilis in infants. Such anatomical changes may be either diffuse, when the inflammatory process involves the entire intestine or extends over a large portion of it, or circumscribed, as in other typical syphilitic affections: in the latter case the upper portion of the jejunum is especially affected. Two forms may be differentiated,—one of infiltration confined to the intestinal patches, the other of irregular tubercles situated in the sub-mucosa, and of about the size of a pea. Both forms are liable to ulceration, which may be distinguished from other forms of intestinal ulceration by the fatty character of their bases and their indurated, punched-out edges. Microscopic examination shows that the process starts as a round-cellular infiltration in the walls of the finest arterial vessels, obstructing their calibre and resulting in an anæmic necrosis. In the diffuse variety the inflammatory process is principally located in the mucous membrane, and leads to fatty degeneration and desquamation of the epithelium.

This affection may explain why children of syphilitic mothers so frequently suffer from severe uncontrollable intestinal catarrh.—*Centralb. f. d. Med. Wissen.*, December 13, 1883. S.

THE SITE OF THE CARDIAC IMPULSE.—Dr. S. Eulan makes the following statements as to the relation existing between the position of the heart's impulse and the line of the nipple.

In the recumbent position the impulse of the normal heart never extends over that portion of the fifth intercostal space lying between the clavicular and parasternal lines.

If, instead of being within, the heart-shock lies without the left clavicular line on the level of the fifth intercostal space, the heart has either been displaced or abnormally enlarged.

In cases where the cardiac impulse is felt in the fourth intercostal space, especially in children and females, a moderate extension of the impulse over the clavicular line must not necessarily be attributed to pathological processes unless some other signs of disease are present.—*Deutsches Arch. f. Klin. Med.*, December 12, 1883. S.

TEST FOR IMPURITY OF IODOFORM.—The examination of iodoform for impurities is conducted, according to the method of

Agema, as follows. Iodoform is shaken with distilled water, and the solution filtered, and to it is added an alcoholic solution of silver nitrate (lunar caustic). The mixture is now set aside for twenty-four hours. Should foreign substances be present in the water, there will be a black precipitate of reduced silver in proportion with the amount of the impurity. Pure iodoform will give by this test only a faint grayish cloud upon the bottom of the glass. All the preparations which had caused toxic symptoms gave a precipitate when tested by this method.—*Centralblatt für Chirurgie*, No. 48, p. 770.

THE RELATIONSHIP OF MALIGNANT DISEASE TO THE FOOD AND ITS TREATMENT BY DIET.—In a communication to the Académie de Médecine de Bruxelles, M. Van den Corput made a suggestive reference to the etiology of cancer (*Revue de Thérapeutique Med.-Chir.*, January 15). Upon considering the geographical distribution of cancer the author found that it is almost unknown in hot countries, and also among certain religious communities in other latitudes which abstain from the use of meat. The only apparent connection between these two classes is the diet. It is apparently, therefore, to an exaggerated animal diet—which at the same time causes an excess of chloride of sodium in the system—that we must look for the principal pathogenetic cause in the cancerous diathesis. This must reside in an infection of the organism, either by certain nitrogenized products susceptible of disturbing or changing the normal nutrition processes, or by certain inorganic elements, such as the phosphates, capable of favoring the histogenesis of neoplasms. A confirmation of this view was found in the rapid emaciation of the patients, accompanied by the decreased discharge of urates in the urine. The application of these views to the treatment of cancer is obvious, but it does not appear that the author has succeeded as yet in demonstrating the correctness of his views by clinical investigation.

SYPHILIS IN THE MONKEY.—M. Martineau reported to the Société Médicale des Hôpitaux that the monkey which he had inoculated with syphilis several months ago has now a syphilitic inflammation of the vault of the palate.—*Le Progrès Médical*, October 20.

EDITORIAL.

THE TREATMENT OF SPINAL CARIES AND ABSCESS.

AMONG the latest achievements of the antiseptic method, which in the fields of abdominal and joint disease has revolutionized modern surgery, may be mentioned the treatment of spinal caries by early evacuation of the pus-cavity and the removal of any carious portion of the vertebral bodies that may be found. The usual methods of expectancy, either by complete rest in the recumbent posture, or by the immovable dressings, do not always prevent abscess nor greatly improve the prognosis when the purulent collection points in the psoas region or elsewhere.

"The treatment of spinal abscess," says Prof. Gross, "is altogether unsatisfactory. Generally several months elapse before the true nature of the disease is ascertained, and then its ravages will usually be found to be of such a character as to render all efforts at a cure utterly hopeless." He also states that "if a free dependent outlet could be formed for the matter early in the disease, the probability is that the patient might occasionally get well."*

Mr. Frederick Treves, the author of the section of Malformations and Diseases of the Spine in the International Encyclopædia of Surgery, of Dr. Ashhurst,† in that place insists upon the occurrence of suppuration in every case of Pott's disease, even where recovery takes place without evident abscess, and recommends early evacuation with the aspirator, or, if the overlying integument be quite thin

where the abscess points, to make a free incision with antiseptic precautions, and also that the wound shall be dressed antiseptically as long as may be necessary.

In a report recently read by Mr. Treves before the Royal Medical and Chirurgical Society of London, he described a method devised and practised by him for removing fragments of bone and evacuation of the purulent collection. In the proposed operation (as we learn from the *Medical Press*) a vertical incision is first made near the outer edge of the erector spinæ muscle, and the sheath of this and of the quadratus lumborum next cut through. The vertebræ are then reached by incising the psoas and following the structures on to the surface of the bone. Ready examination of the vertebræ is thus rendered possible; and should sequestra exist, their removal is rendered perfectly easy. In the first case, operated upon by Mr. Treves in this manner, the necrosed portion of bone was readily removed, and the patient did very well after the operation. The same result, as far as the operation went, was reported of two other cases; but one of them, a boy, subsequently succumbed to pre-existent disease of the lung and other complications.

Mr. Treves points out that the gravity of caries of the vertebræ depends principally on the depth and inaccessibility of the morbid action and not upon any peculiar pathological features which it possesses. Mr. Bryant, in the discussion, spoke favorably of the operation mainly because it would afford an easy outlet for the pus, rather than on account of the opportunity of removal of the diseased bone, which does not always exist. Mr. Savory, however, questioned the applicability of the operation, since it gives a very inadequate exposure of the parts affected for the removal of bone, and where sequestra do not exist, the operation of a purely exploratory character is not justifiable. Mr. Barwell also called attention to

* System of Surgery, Sixth Edition, Phila., 1882, vol. ii., p. 122.

† The International Encyclopædia of Surgery, vol. iv. New York, 1884.

the fact that removal of a large amount of diseased bone would not be feasible, and the diagnosis would always be a doubtful one as to whether any sequestra really were present.

It is hoped that Mr. Treves's communication will direct professional attention anew to the treatment of a class of cases that too long has been an opprobrium to medicine.

THE AMERICAN ANTI-VIVISECTION ASSOCIATION.

THE first anniversary of the American Anti-Vivisection Association, held in this city on the 30th of January, calls for some comment by the medical press. The work during the past year has been principally directed towards enlisting professional and public sympathy in its work, and distributing pamphlets defending the object of the organization, which is to secure the regulation of vivisection by law. The question, as it now stands, would be simplified and very much aided towards a satisfactory solution, if each party to the controversy with regard to the practice of vivisection could be made to better understand the position of the other.

In the first place, it may be said in behalf of American vivisectors, taken as a whole, that they repudiate the definition of a vivisector given by M. de Cyon; they do not regard the sufferings of animals with pleasure or even with indifference; they deplore the necessity of inflicting pain or sacrificing life, but regard the ends of science as of sufficient importance to humanity to justify the course they pursue. This, at least, appears to be the opinion expressed by the author of a recent work which has been everywhere received with high encomiums as a fair, logical, and temperate defence of vivisection;* it also is the feeling which has been expressed by prominent physiologists

who are now engaged in original research. No exception can be taken to the statement that all vivisection experiments that are not distinctly scientific in their object are unnecessary, and therefore cruel; and being cruel, should be condemned by every right-minded man or woman. The experiments of Brachet, who tortured a pet dog to death to test the limits of his affection, and the atrocious performances of Mantegazza, who invented ingenious methods of causing extreme physical agony to living animals, are not considered defensible by physiologists generally; and many members of the medical profession, although in favor of original research, are also decidedly opposed to the use of animals in the lecture-room to illustrate well-known surgical or physiological facts.

On the other hand, it is claimed in behalf of the Association that its object is not the abolition of vivisection entirely, but its restriction within proper limits. The names of the incorporators and managers of the American Anti-Vivisection Association sufficiently vouch for the propriety of the objects sought to be attained by the organization, and for the intelligent and fair consideration which will be given to the subject. Dr. Thomas G. Morton, of this city, is the president of the society for the current year.

If a disposition could be manifested by those engaged in vivisection to concede a little in return for greater security in carrying on necessary experiments, and they could be persuaded to formulate the conditions demanded by science, it is possible that a law might be framed in this State that not only would be satisfactory to those who are opposed to unnecessary vivisection, but which would also react to the benefit of science by increasing the value of the work done, and so establish beyond question the value of properly-conducted scientific investigation in experimental therapeutics and in physiology.

* *Physiological Cruelty*. By Philanthropos. New York, 1883.

NOTES FROM SPECIAL CORRESPONDENTS.

LONDON.

THE medical events of the present time are the honors conferred upon members of the profession. Ireland had to be satisfied with the knighthood of a surgeon; though not long ago Dublin could boast several medical baronets. England has been more fortunate. First came Andrew Clark, senior physician to the London Hospital, the medical adviser of the Premier and of a large proportion of the titled folks in Great Britain. Steadily, by careful pains and clinical acumen, Dr. Clark worked his way upwards at the London Hospital and among society. It is said he so impressed Mrs. Gladstone by the manner in which he discharged his duties at an institution with which she was connected that she induced her spouse to place himself in his hands, with results most satisfactory to all concerned. Sir Andrew Clark, Bart., like most of the leading consultants of the immediate present, has contributed little to medical literature; but that little has always been sound and valuable. He drew attention to "Fibroid Phthisis," and caused the profession generally to realize that there were other forms of lung-consolidation than the truly tuberculous form. He has also kept the subject of "Renal Inadequacy" well before the profession. Dr. Clark's observations are always worthy of close attention; and his manner is impressive, his speech brief, to the point, and epigrammatic. Though not a prolific writer, it must not be supposed that his contributions to medical literature are confined to the two subjects mentioned above. One great matter Dr. Clark has done which ought to earn for him the gratitude of the affluent, and that is, he has always pointed out clearly, unswervingly, and incessantly the evil consequences of a dietary too rich in albuminoids, especially when accompanied by alcoholic indulgence. He is neither a teetotaller nor a vegetarian; yet he may be called "the apostle of temperance" in matters of eating and drinking. Whether all who ought to be grateful to him are sufficiently thankful it is not in my power to affirm. The next is the veteran oculist, William Bowman. Middle-aged men remember the ponderous, but valuable as it was weighty, "Cyclopædia of Anatomy and Physiology" edited by Todd and Bowman, issued in parts, and containing in pretty full detail the best and most recent information on many and varied subjects,—a work of the very highest character. He was then Professor of Physiology and Anatomy at King's College. In 1842 he gained the Royal Medal of the Royal Society, and has been made a corresponding member of numerous foreign scientific socie-

ties. There is no more revered name in the ranks of medicine than that of Sir William Bowman, Bart. Even better known to the world, especially the world of surgery, than either of the above, is the name of Joseph Lister, "the apostle of the antiseptic treatment of wounds." His earlier contributions to the subject first attracted public attention when the late Prof. Sir James Simpson, Bart., and the late Prof. James Syme were worrying each other in their incessant warfare in Edinburgh, when the great obstetrician was advocating acupressure for the arrest of arterial bleeding,—an antiseptic measure in its way. Those who remember that time know how wonderful it was held to secure union by the first intention; how the French surgeons never attempted anything of the kind, but stuffed charpie into the green surgical wounds right away; and German surgery was about the same. Steadily, sturdily, unfalteringly, Lister propagated his views, and slowly, often unwillingly, converts announced their acceptance of his views, or at least his practice. At last French and German surgeons awoke to the teaching of the new faith, to the inestimable benefit of their patients. Even those who still contend against the germ theory have accepted the practice of the most scrupulous care and cleanliness in the infliction of surgical wounds, and in the dressing of the said wounds, with the most gratifying results. Sir Joseph Lister, Bart., has also received the gold medal of the Royal Society, and been elected a corresponding member of a legion of foreign societies, with other honors. He has earned for himself an honored and undying name in the annals of medicine. If the medical profession is honored by baronetcies being conferred upon these three gentlemen, the baronets of Great Britain may be congratulated on these accessions to their ranks. Still there is no medical peer. A curious instance of the survival of prejudice! Yet in these days of sanitation, of preventive medicine, of attention to the public health, one might imagine that a medical peer might not be quite out of place among our hereditary legislators. But his time may yet come. The showers of honors which have fallen right and left lately make mere knighthood a mark of disdain, or the indication of the want of means to sustain the honor of an hereditary title. Whatever the government, or our august lady the Queen, mean by this profuse distribution of handles to names, is unknown to the writer, and therefore he cannot instruct his readers.

Another medical event is the sudden appearance of a new medical publishing firm. Some little time ago an announcement appeared that the popular publishers Messrs. Cassell & Co. intended to issue a series of manuals for students of medicine. Instead of dealing with medical authors *seriatim*, they agreed with Malcolm Morris, known to the

profession as the author of a treatise on the "Diseases of the Skin," rather of a practical than of a comprehensive character. Morris is what very few men in the profession are,—viz, a really good business-man, and thoroughly fitted for his position; a right good-hearted fellow, too, who would live and let live. Through him a series of manuals have been arranged for, which will be of service to their writers as well as their readers. The first was "Elements of Histology," by Klein, which at once took its position, and asphyxiated Quain and Sharpey's massive work, indispensable before on account of its chapter on histology. Then followed "Surgical Pathology," by A. J. Pepper, of St. Mary's Hospital,—a work whose *raison d'être* has been demonstrated by its sale. Instead of massive, comprehensive works, separate manuals are provided, each dealing with its own subject-matter proper. For instance, "Human Physiology," by Henry Power, will be a work at once in immediate demand. Of course, human nature would not be what it is if Malcolm Morris was regarded as a benefactor by those authors whose works are threatened with extinction by these new books. But the rising generation of medical men will hold his name in respect.

Medical works other than students' manuals will probably issue before long from this last accession to the scanty ranks of medical publishers. The first medical publisher was Churchill, who for long had the field practically to himself; but first one and then several more publishers began to think the pickings of medical books were worth having. Whether the new recruit will go the length of essaying a medical journal or not is a matter on which opinions are divided. It is not unlikely that such an attempt will be made, though the field seems pretty well occupied by existing journals. With you a medical journal springs up somewhere in a night, and, instead of disappearing again as swiftly, holds on its way and survives. It is far different with us. There is little or no local *esprit*. The metropolis overshadows the provincial towns here; and though Birmingham has a puny medical journal, Liverpool a medico-surgical journal, and Bristol a journal, these local efforts only maintain a struggle for existence by comparison with journals of like character ayont the Atlantic. From this it is not to be inferred that the only journalistic power in the medical profession is to be found in London; only its amount there overshadows the rest of the land. The *Midland Medical Miscellany* covers an area which can well carry a medical journal of its own. As to medical literature, the tendency is more and more to reissue American works here, which seem to be largely taking the place of the works on special subjects which used to appear. A work on Practice of Physic, by the late Dr. Hilton Fagge, was

announced, but whether it will be published after his untimely death or not is not yet apparent. There could have been little novelty in it, as a matter of course. A work on Obstetrics, by Robert Barnes and his son Fancourt, is announced to appear shortly. Otherwise the advertisements tell of familiar works, well known. "The Physiological Factor in Diagnosis," by the writer, has reached a second edition already, which tells that it fills a niche hitherto unoccupied.

The new year, however, commences with what promises to be very useful, especially to the large bulk of the profession, the men who toil for scanty rewards in the humbler quarters of our towns and many rural communities. Perhaps some others, too, of higher social grade may avail themselves thereof. The increasing income of the British Medical Association is enabling it to do many things, such as granting sums for scientific research, giving medals to deserving members of the profession, or helping a medical man oppressed by a vexatious appeal to the law by which sundry malevolent persons may practically subject him to a heavy fine. Now the proposition is made of "a medical sickness, annuity, and life-assurance society." In your country an average man, with pains and moderate thrift, can lay aside some surplus income to educate his children and keep himself when his days of capacity to labor are past. Here, unfortunately, it is not by any means always possible for a medical man to do this. Over large areas the working expenses swallow up the earnings, leaving barely enough to keep up appearances. For years this goes on; and, unless the medical man has a son who can step into the practice as his father falls out, the day comes at last when the daily bread runs short. The proposition is to institute such an insurance society on the basis of the British Medical Association, which could provide the funds, be security, and put any surplusage into the pockets of the members, instead of those of the shareholders in insurance companies. The design seems an excellent one, and deserving of all support that can be given to it. It is proposed that sums of from two to four guineas weekly during sickness be arranged for; and that these may be conjoined to certain yearly allowances payable on the insurers reaching sixty-five years, and continuing till death; also that sums at death may be secured, as is common now. It is suggested at present that the age of forty-nine next birthday should not be the ultimate limit for would-be insurers, though it might be well to fix this limit for the working of the scheme when once fairly a-going. It will thrive, doubtless, if well arranged and supervised by competent persons; and both conditions are surely feasible. It is to be hoped that there is no member of the profession so poor a bread-winner, so handicapped with a fam-

ily, or so thriftless that he cannot manage to insure in this proposed arrangement. It will be a very bad day for the public, and no gala-day for the profession itself, when the last struggling poor man takes his diploma and enters upon the field of practice. But the large percentage of poor men, poor in other senses than the mere need of money, who have entered the ranks of medicine in the past has done injury to the profession in that in the struggle for existence they may have stooped to much that is undesirable. It is not merely that such men choose to take up a lowly social status themselves, but they submit to what is very undesirable for the profession at large, and educate the laity to take like liberties with other and better men. It is sad to listen to the just complaints of a respectable medical man with one of these "brothers" on his flank. When all other measures fail, the second fiddle reduces his fees and awaits the result. To a large number of social units a "Dr." is a doctor, just as a grocer is a grocer; the wares of one and the worth of the other are identical; and, of course, they purchase the cheaper article. After pursuing a career of this grovelling kind until years have brought it to an end, this medical man is ready to accept the charity of the benevolent, and gets some measure of it. Of course, how far loyalty to his profession has been a factor in the calculations of this unit of the profession, and self-denial another, are matters upon which opinions might differ. But, without being uncharitable or ill-natured, one may suspect that he has looked little beyond his own self-interest, and has not been particularly clear-sighted about that. He has made himself out to be quite on an equality with his professional brethren not by rising to their height, but by striving to drag them down to his own status, by backbiting and defamation, by pointing out their mistakes, and other like means of doing them injury. He is not now so commonly found as he was, this noxious creeper, but he is yet to be seen in the hedge-rows oftener than is good or beneficial. His extinction is threatened by the increasing severity of the examinations, which terrify him dreadfully, and soon he will be largely non-existent. It is not his monetary poverty which renders him so objectionable; it is merely that his want of coin throws up his qualities in stronger relief. If he were not pinched, perhaps he would avoid some of the paths he treads. But in poverty he stoops to almost anything which will put a shilling into his pocket, and then clamors to be respected and treated courteously as an honorable member of a learned profession. No wonder his claim is not always admitted.

Now that this section of the medical profession is diminishing, there will be a fairer prospect for other men in the humbler ranks of the profession, and it is to be hoped that this new departure by the British Medical

Association will be welcomed by what may be termed the rank and file of the profession. If so, it will most certainly be to the advantage of all. If a man can so be helped to make some provision for himself, instead of drifting on to the inevitable end in hopeless lethargy, it will be a work of brotherly kindness; while a great many men, willing but scarcely able to see how to help themselves, will find this movement give them a friendly boost. Not that poverty is a vice, or even a crime; but it throws up character in its strength, and, what is worse, its weakness. Consequently, if an element of thrift can be lent to those who are of themselves unequal to thrift, it is a boon to them. Placed on a basis of mutual brotherhood, such a scheme is more attractive than the prospectus of a new company, about which all men with a modicum of prudence would have their suspicions. It will be necessary for the financial success of the new move that it be in turn prudent about the selection or accurate appraisal of lives. Nor would the post of medical adviser to the insurance company seem to be highly attractive. It would be a most invidious post for an individual, and the danger of acting harshly towards a medical brother to whom insurance may be of the first moment, is one which most persons would like to avoid, and yet by such kind-heartedness may do detriment to a most deserving movement. The class of men to whom such a scheme is full of promise is just that where a large number of doubtful lives are to be found. Much poverty is the result of undue indulgence in alcohol,—undue in the sense of being beyond what is good for the individual either in person or in purse,—and yet the vice is capable of much careful concealment. Such lives are notoriously "bad from an insurance point of view," being liable to be cut short by intercurrent disease which a healthy organism could readily throw off. How to protect the new venture against this class of life will exercise the ingenuity of those who are at the helm. As to the bulk of the profession, it will be a distinct advantage. For there are extremes; and while at one end we find medical baronets, at the other we find men who can hardly scrape together a bare living; and provision for the one extreme is as desirable as conspicuous honors are for the other. All success, then, to the new "friendly society" aspect of the British Medical Association!

J. MILNER FOTHERGILL.

CHICAGO.

IN consequence of our Board of County Commissioners forbidding the delivery of unclaimed pauper dead to the medical schools, a general raid has been made upon the graveyards of small towns in the State, for dissecting-material to meet the demands

of this city; and not a little trouble has been experienced by many of the colleges to keep their tables meagrely supplied. Occasionally the friends of deceased persons come to the city, and, by process of law and otherwise, investigate the dissecting-rooms in quest of missing bodies, not always unsuccessfully. At such times there is a good deal of popular excitement, and our Board of County Commissioners are roundly abused, and justly so. It appears there is some religious influence holding the Commissioners to their present course, as a large majority of our pauper dead come from one denomination.

A somewhat peculiar and interesting bit of history has been developed in connection with the life of a monstrosity. About thirty years ago a respectable couple had born to them, in this city, a boy without arms. To one shoulder was attached a portion of a hand or flipper having three ill-formed fingers at its extremity; the other shoulder had a rounded protuberance only, bearing no indication of amputation in utero. The child was well formed in every other particular, and grew to be a bright, intelligent, and successful business-man. He wrote an exceptionally neat and rapid hand, the movements of the pen being aided by his mouth. About two years ago he married a young lady of good family, and last autumn he died of pneumonia. At the time of his death his wife was far advanced in pregnancy, and lately gave birth to a boy having the same deformity as the father, with this slight difference, that there are in this case no rudimentary fingers. It may be stated in this connection that the parents manifested much anxiety regarding their expected offspring.

As an illustration of the working of our lunacy laws, I will relate a case that came into court a few days ago. A lady of 60 years was charged with insanity, and the expert, medical, and lay evidence clearly went to show the patient (prisoner) to be of unsound mind,—that during the past two years her character, habits, etc., had undergone a complete change, and that her acts and faculties showed pretty clearly that she was suffering from the early stage of senile dementia. The jury brought in a verdict of insanity, whereupon the counsel for the defence took the extraordinary step of having the jury polled, and demanded a new trial; and, strange to say, the judge set the verdict aside and surrendered the prisoner to the custody of her lawyer till such time as he, the judge, might decide upon another trial. The defendant in this case is wealthy and has full control of considerable means. It is not, however, a case where the least wrong can be attached to the motives of the relatives.

Our Home for the Friendless has long been receiving foundlings, and amongst this class of inmates the mortality has been frightful, but one infant under three months having

survived more than three months after admission. This has been true not of one but of several years past. In view of this state of things, it has been advised that children under one year shall not be admitted. M.

January 18, 1884.

PROCEEDINGS OF SOCIETIES.

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting was held January 17, 1884, FORDYCE BARKER, M.D., LL.D., President, in the chair.

ANTISEPTIC DRESSINGS AS THEY ARE USED IN THE NEW YORK HOSPITAL. A DEMONSTRATION,

was the title of a paper read by R. F. WEIR, M.D.

The matter he was about to present, he said, might be of little interest to the hospital-surgeon; it was more especially intended for the benefit of the general practitioner. There are some differences in the details of antiseptic dressings as now used and formerly, but they still involve the same principles originally set forth by Sir Joseph Lister. The object sought for in the treatment of wounds is to place them in a condition to permit of the best drainage, to keep them at rest without frequent renewals of the dressings; and in order to do this it is necessary to resort to chemical substances which will prevent putrefaction. He did not wish to enter upon the theoretical part of the subject, but one could not help thinking that the development of micro-organisms was associated with decomposition either as a cause or an immediate concomitant effect. The researches of Lister had shown that the healthy tissues had to a considerable degree the power of resisting the development of germs, notwithstanding the fact they found entrance into the air-passages and alimentary tract. When the tissues became abnormal a better soil was prepared for the development of micro-organisms. The object of antiseptic dressings was to neutralize the development or effect of disease-germs, and, until recently, this was commonly done by the use of carbolic acid or iodoform. Carbolic acid, however, was volatile, and unless used fresh could not be depended upon. Again, carbolic acid and iodoform were both liable to produce toxic effects. Since a year ago, in March, he had been using corrosive sublimate. He was led to bring it before his audience to-night from having witnessed its extensive use abroad during the past summer, where it had produced excellent results. It was applied to wounds in several different ways,—in the form of gauze, cheese-cloth, or mull, impregnated with the salt and applied to the wound. The absorbing power of the

gauze was increased by boiling in a weak solution of soda or muriatic acid, but more recently they had obtained it prepared directly from the manufacturers. To avoid too frequent and early changes of the dressing, substances of greater absorbent powers were applied, such as peat. Formerly the white was used in Germany, but now the black mixed therewith was preferred, as it was supposed to possess in itself antiseptic properties. Dr. Weir did not think it possessed much advantage over the white. Neuber left it on in some cases forty-two days without a change of dressing. This great length of time, however, was not necessary, as the tendency to septic absorption passed away in ten to fifteen days. One objection to it and to other absorbent dressings was that they were too bulky, and were in the way of the application of splints in compound fractures, when a more frequent inspection should be made. Jute, formerly carbolized, but at present used with the corrosive solution, was an excellent absorbent dressing, particularly the finer quality now to be obtained of the importer. The pulp of wood, ready to be made into paper, was also an excellent dressing for wounds, and was capable of absorbing thirteen times its weight in water. The absorbent power of jute was from four to six, and of peat nine to ten, times their weight of water. An excellent cheap dressing, which could be obtained anywhere in our own country, was common wood-moss. It was necessary to bake it and destroy the germs which it contained before using it. It would take up four times its weight of water. These substances were easily prepared with the corrosive solution. The jute and moss were dipped in a solution of one part to a thousand, fifty parts of glycerin being added. The next day they were wrung out and allowed to dry. The gauze and cotton-batting were prepared as follows: Corrosive sublimate, twenty parts; water, four thousand four hundred and eighty; glycerin, five hundred. The specimens should be freshly made, for the corrosive sublimate was disposed to change into calomel. Most of the time during the operation a solution of the bichloride, one part to a thousand, sometimes to two thousand, was allowed to trickle over the wound. The bedding and other parts of the body were protected by passing the injured limb through a hole in a rubber blanket. The catgut ligatures were prepared by a ten minutes' bath in a one to one hundred solution of the bichloride, and afterwards for ten to fifteen hours in a solution of one to one thousand, and kept in absolute alcohol. Sometimes they were prepared after Kocher's method, put into oil of juniper, and afterwards into absolute alcohol. Dr. Weir had seen no poisonous effects from the bichloride, but the possibility of this might be guarded against by using the boro-salicylic solution.

The wound was preferably closed with catgut, the continued suture being employed. Sufficient space was left for a drainage-tube. The decalcified bone tube was used. They were specially serviceable in amputations, etc., where it was necessary to get primary union, as they became absorbed in five or six days. Having cleansed the wound carefully with the running solution, several sponges should be placed over it to carefully compress it. Replace them by sublimate-gauze, with which make pressure, then apply more of the handkerchiefs. Secure them by sublimate-gauze bandage, then apply the absorbent dressing of peat, or other substance, done up in bags of suitable shape and thickness. Some smaller ones may be added, bound firmly in position by crinoline bandage dipped in the antiseptic solution. The impermeable outer covering of Lister was not employed. The dressings were not changed until signs of something going wrongly manifested themselves. A persistent temperature for twenty-four hours was sufficient indication, in Dr. Weir's opinion, for a change of the dressing. The instruments were put into a five per cent. solution of carbolic acid. Dr. Weir then dwelt somewhat upon the subject of cleanliness, to which he attached great importance, although he believed that it could not replace germicides. Excellent results had been obtained by its observance alone in the hands of Mr. Tait and others. In the New York Hospital, before proceeding with an operation, the parts were washed with soap and water, and then with a mixture of turpentine and alcohol, two ounces to the pint. Importance should be given to the preparation of the sponges. They were first freed of sand by beating, then washed in warm, not hot, water, then placed in one to one thousand solution of permanganate of potash for twenty-four hours. They are then washed in warm water, then bleached by immersion in a solution of one to one hundred of sulphide of sodium, to which is added a one-fifth part of a watery solution of hydrochloric or oxalic acid, of a strength of eight to one hundred, stirred with a stick a few minutes until whitened, again washed in warm water, and allowed to stand in running water, then put into a carbolic acid solution, one to twenty, or in a solution of bichloride of mercury, one to one thousand, in which they are kept until used. Thus prepared they were cheap, and need not be again used, especially after operations in which they are liable to absorb contaminating material. If again used, they are first thoroughly washed in running water, kept for some hours in a weak solution of carbonate of soda, then placed in the antiseptic solution.

In certain wounds of the body, as of the mouth, the rectum, etc., it was more convenient to employ iodoform. It could be applied rubbed into mosquito-netting or other

material. More than forty-five grains would give rise to poisoning.

Perfect rest was sustained, even in minor operations; and an easily cleaned splint was that made of enamelled iron.

Dr. Weir then gave the statistics taken from the practice of Billroth, Volkmann, hospital records, and others, going to show that antiseptic dressings did "pay." He himself had done thirty-five amputations without a single death,—one hip-joint, seven knee-joint, seven thigh, nine leg, seven arm, and two forearm amputations.

DISCUSSION.

Dr. A. C. POST, being invited to open the discussion, said he had been much interested in the remarks made by Dr. Weir, and he himself was fully convinced of the value of what was known as antiseptic surgery, although he was not prepared to acknowledge the necessity of all the details of the treatment as given by the author. This was certainly true respecting the treatment of wounds of minor importance. He called attention to one application to wounds which Dr. Weir had not mentioned in his remarks, namely, the subnitrate of bismuth. This he had dusted over the wound in many cases of minor injury, and then applied an ordinary dressing, and had obtained excellent results thereby.

Dr. J. D. BRYANT referred to experience with the antiseptic methods as used during his service as interne in the Bellevue Hospital in 1868 to 1871. During a part of that time he treated twelve cases of compound fracture. The wound was washed with a solution of carbolic acid, and dressings applied soaked in a solution. The strength was 1 to 80 or 1 to 120, according to the purpose for which it was employed. Only two of the twelve patients died, one of them being a very severe case indeed. The limb was also put up in an immovable plaster-of-Paris apparatus. Since the spring of 1871 he had employed the Lister treatment of wounds, but the last few months had been trying the virtues of the bichloride solution, 1 to 2000. There had been but two cases in which unfavorable symptoms occurred under its use, and in those the difficulty could be traced to negligence. He had entire confidence in antiseptic treatment, and related two cases illustrative of its value in a high degree, one being a case of large scrotal hæmatocele, and the other a tumor of the parotid gland. He thought it important for the surgeon to simplify the antiseptic method if possible, so that it could be carried out with ease and efficiency by the general practitioner. The present times pointed more favorably to the use of bichloride. He employed catgut soaked in oil of juniper.

Dr. L. A. STIMSON thought the subject a complex, not a simple one; not one which related simply to the employment of an anti-

germ dressing. For him who believed that all the complications in the progress of wound-healing were due to the influence of micro-organisms the problem was a simple one; all that was necessary, in such a man's opinion, was to find some efficient germicide, and employ dressings which would tend to prevent the entrance of germs, and use the chemical which would kill any that found their way to the wound. But for the man who thought complications could also arise from some other source, although that other source was unknown to him, the question was a complex one. It was true that germs might cause septicæmia, but it could not be logically argued from that fact that all cases of septicæmia were due to the influence of germs. Moreover, it was not logical to conclude that a dressing applied because it is supposed to be antiseptic or germ-destroying is of benefit only because of its germicidal properties. The beneficial result obtained from its employment may be due to some other factor than the simple one of power to kill micro-organisms. For instance, it had been shown by Dr. Weir that the carbolyzed dressing employed for so many years had lost its carbolic acid by evaporation, and yet excellent results were obtained by its use. Now it has been found that the bichloride will become changed after being kept for five or six days and assume the form of calomel, and yet a much older preparation had been employed with excellent results. Peat had been employed with good results in its natural state, and yet Dr. Stimson had learned by certain experiments that peat was full of germs. But, then, brilliant results and disastrous failures had followed the employment of every antiseptic. The experience of no single surgeon was sufficient to test the value of all the antiseptics in all or a single department of surgery. Nevertheless, Dr. Stimson had faith in antiseptics in purifying the patient, the surgeon, and his assistants, and the instruments; in the employment of drainage and compression; and rest should also be secured. While he believed in the employment of antiseptic methods, he did not overlook the fact that other conditions might give rise to complications, to fever and sepsis, however well antiseptic precautions might be carried out. This was especially true where the bones were operated upon. The surgeon, therefore, who took unnecessary risks, placing entire dependence upon antiseptic methods for the prevention of complications, was rash to the verge of criminality.

Dr. A. G. GERSTER pointed out certain advantages which corrosive sublimate possessed over carbolic acid as an antiseptic. One of the most important was that it did not tend to dissolve the blood-clots which occluded the mouths of the divided vessels and gave rise to a bloody oozing, necessitating an early change of the dressing. During the past six

months he had employed the bichloride in his service at the Mount Sinai and German hospitals, and with entire satisfaction. He had sought to simplify the antiseptic dressing so that it could be easily made use of by the general practitioner, and had found that common sawdust soaked in the bichloride solution, one to five hundred, and then dried and put away in tight boxes until used, was a very cheap and as good a preparation as the most costly and fanciful. Ordinary cotton-batting prepared with the bichloride was also an excellent dressing. He mentioned a case of fracture of the elbow-joint in an aged man, in which it was employed, improvised, and the patient made an excellent recovery. He thought much better results were now being obtained since the thorough carrying out of antiseptic surgery. It was true that now and then unexpected suppuration would take place, even when the antiseptic dressings were applied seemingly with the greatest care. But usually in such cases the vigilant surgeon would be able to find some neglect in the details of the treatment. Very often, in his opinion, the trouble was due to the direct introduction not only of micro-organisms, but even of lumps of dirt. He mentioned a case of recurring dislocation of the shoulder-joint in which the capsular ligament was found stretched. He cut down upon the joint, excised a portion of the ligament, and applied sutures. Within a few hours the temperature indicated sepsis, and he immediately removed the dressings, opened the wound, and found three or four ligatures the centre of collections of pus, while the other ligatures, not taken from the same strand of cut, were perfectly clean. In that case, doubtless, the one ligature carried the germs of disease.

Dr. WEIR, in closing the discussion, said that he agreed with both Dr. Stimson and Dr. Gerster, although they apparently took opposite sides of the question. He agreed with Dr. Stimson that there were cases in which sepsis would develop in spite of the most careful antiseptic precautions, and that, therefore, we were not justified in undertaking hazardous operations where the object to be gained was not of importance. He did not think that we yet had absolute control of all the elements of wound complication; the antiseptic method was only one of the steps towards perfection in treatment. With regard to subnitrate of bismuth, referred to by Dr. Post, it had not so much control over erysipelas as had some of the other agents mentioned.

OWING to the secession of the old New York County Medical Society from the American Medical Association, a new county society has been formed in that city, in order to be in affiliation with the other societies throughout the country.

NEW YORK PATHOLOGICAL SOCIETY.

A STATED meeting was held January 23, 1884, GEORGE F. SHRADY, M.D., President, in the chair.

NEURO-FIBROMATA COMPLICATING SPINA BIFIDA.

Dr. ELLIOTT presented a specimen illustrative of this affection, the case being that of a child which had come under the care of Dr. J. M. Roberts for orthopædic treatment. There was accompanying double talipes. Pressure upon the fontanelles caused fluctuation at the lumbar tumor. An injection of a fluid was made into the tumor in the course of the treatment, but was followed by convulsions, and some hours later by death. Dr. Elliott was of opinion that the tumor was due to an arrest of development in the epi- and meso-blast taking place early in intra-uterine life.

HYDRO-SALPINX.

Dr. BROWN presented the ovaries and Fallopian tubes removed from two different patients. In the first case considerable hemorrhage followed the birth of a child, and the patient was slow in recovering from the confinement. About six weeks later she began to develop symptoms of melancholia, and suffered from severe pelvic pains. A tumor was felt in the posterior *cul-de-sac*, which was very sensitive, and supposed by Dr. Brown and Dr. Dawson to be due to prolapsus of the right ovary. At the laparotomy the left ovary was found cystic, and both tubes were the seat of hydro-salpinx. The patient was much relieved by the removal of the diseased organs. In the second case the patient had suffered for some years from pelvic symptoms. She was doing well since the removal of the dropsical Fallopian tubes.

VISCERAL LESIONS IN A CASE WITH EPILEPTIFORM ATTACKS.

Dr. R. W. AMIDON gave the history of a case of epileptiform attacks occurring in a boy 7 years of age, of very bright intellect, coming from a neurotic family. When 3 years of age he suffered from measles, which were followed, according to the mother's statement, by general oedema; and at about the same time spells developed, which were treated by the attending physician with bromide of potassium, ten grains three times a day. At the time when Dr. Amidon saw the patient, there was an eruption from bromism upon the legs, face, and forehead, which readily disappeared on discontinuing the medicine. Respecting the attacks Dr. Amidon said the following facts were against the idea of epilepsy: first, he had never known a person to have seventy-two regular epileptic convulsions in as many hours, and yet retain comparatively good health and a clear head, as this

patient had done. Second, the child had a distinct recollection of each convulsion, and was always able to foretell their occurrence. Third, it never uttered a cry before the convulsion. Fourth, it never bit the tongue, nor frothed at the mouth. Fifth, there was preservation of sensibility and resistance to opening the eyelids during the attack. Certain of these facts led to a diagnosis of hystero-epilepsy and a favorable prognosis. The remedies employed in the treatment were aqueous extract of opium, *cannabis indica*, quinine, iron, tonics, regulation of the diet. There were symptoms of improvement under treatment, but relapses occurred. Death finally took place from œdema of the lungs and heart-failure. At the autopsy the stomach was found dilated, the spleen enlarged and congested, the kidneys congested, with atrophy of the cortex. The right ventricle of the heart was dilated, and there was fatty substitution in its walls; the left was concentrically hypertrophied; the right auricle was thinned and dilated. The brain was normal and well developed. Had the condition of the stomach been recognized during life, he should at once have resorted to hypodermic medication.

PLEURISY WITH PERICARDITIS.

Dr. FERGUSON presented specimens illustrating these affections, removed from a man who recently died in the hospital with the usual symptoms. He also presented specimens illustrating the condition known as surgical kidney. Independent of the recent lesion was found ankylosis of one knee and ankle, enlargement of the distal end of the femur, fatty degeneration of the muscles of the leg, and atheroma of the vessels, due to an injury which the patient had sustained twenty years ago, the nature of which he did not remember.

DILATATION OF THE STOMACH.

Dr. JOHN C. PETERS presented the stomach of the patient whose history he had reported in part at a recent meeting of the Society. At the autopsy the stomach was found dilated from four to six times its normal size, due to constriction at the pyloric extremity. There was no tumor nor malignant disease.

Dr. AMIDON asked whether any benefit had been derived from medication by the mouth.

Dr. PETERS replied that to have given medicine by the mouth would have been equal to throwing it into a swill-pail. It would not at all have been absorbed by the mucous membrane of the stomach.

CARCINOMATOUS TUMORS OF THE CALVARIA.

Dr. H. N. HEINEMAN presented the calvaria of a patient, a woman, who, in 1881, suffered from carcinoma of the right breast,

which was extirpated by the late Dr. Mason. Recently she appeared at the Mt. Sinai Hospital, presumably suffering from carcinoma of some of the internal organs. At her death, however, these were all found unaffected by malignant disease. There were some infiltrated glands in the axillary and cervical regions. The right side of the calvaria showed several bony growths,—one upon the petrous portion of the temporal bone causing considerable pressure upon the medulla, and one upon the sphenoidal bone giving rise to exophthalmus. The diploë was infiltrated, but the dura was not affected.

Dr. HEINEMAN also presented specimens illustrative of acute general tuberculosis, occurring in a child one year of age, recently arrived by steerage-passage from Europe.

CARCINOMA OF THE STOMACH.

Dr. BEVERLY ROBINSON presented a stomach which was the seat of a cancerous tumor at the pyloric end, the interest of the case relating to the diagnosis. The surgeon of the hospital was unable to recognize the tumor, which Dr. Robinson, as he believed, was able to feel on several occasions. He was of opinion that at certain times it was so covered by the liver as to be hidden from the touch, while at other times the position was such that it could be distinctly recognized by palpation.

OSTEOLIPOMA (?).

Dr. J. A. WYETH presented a tumor which had been removed from the radius, about one inch from its carpal extremity. A combination of a bony and a fatty tumor is rare, but the present case seemed to illustrate that condition. The lipoma, which consisted of two lobes of considerable size, was attached by a pedicle to a small exostosis of the radius. He was inclined, however, to accept the view suggested by the President, that the fatty and the bony growths had no special pathological relation to each other, but the presence of the one may have given rise to the other by irritation.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, JANUARY 10, 1884.

The President, DR. TYSON, in the chair.

Specimen of osteomyelitis of tibia. Exhibited by CHARLES M. WILSON, M.D.

GEORGE L., æt. 42, was admitted into the surgical ward of the Pennsylvania Hospital November 26, 1883. Sixteen days previously he had been knocked down on ship-board and had sustained a wedge-shaped fracture of the tibia and an oblique fracture of the fibula of the right leg about the middle. When admitted, the fragments were in

malposition and partially united. There was considerable deformity, the lower fragment of the tibia being tilted up and overlapping the upper fragment. By appropriate treatment the fracture was retained in fairly good position, and the case was progressing favorably until the afternoon of December 26, just one month after admission, when he had a severe chill, followed by a temperature of $103\frac{1}{2}^{\circ}$ F. He complained of violent pain in left shoulder-joint. He was treated with salicylate of sodium. Next morning his temperature was $102\frac{3}{4}^{\circ}$ F., with intense pain in both shoulders and elbows. The same treatment was continued, under the supposition that the case was one of acute articular rheumatism. On the afternoon of the second day, he had a severe chill, with an evening temperature of $104\frac{3}{8}^{\circ}$ F., and a presystolic mitral murmur was detected. Dr. Wilson now considered the case to be one of pyæmia, and gave massive doses of quinia, stimulants, and digitalis, but he steadily grew worse, and died of exhaustion on the morning of December 30. Post-mortem twenty-six hours after death. Rigor mortis marked. Body well nourished. Posterior portion of body much discolored. Extensive ecchymoses over arms and shoulders. Smaller patches over abdomen and chest; one and a half ounces of clear serum in the pericardial sac, with many ecchymoses over the surface of the heart. Both sides of heart relaxed and partially filled with post-mortem clots. The valves on right side appeared normal. The aortic valves were incompetent, and their free borders were roughened by recent vegetation. There was also some slight thickening and contraction. The mitral valves showed old thickening as well as signs of recent inflammation. The endocardium of the left ventricle showed numerous spots of ecchymosis. The heart weighed sixteen ounces, and its tissue was a good deal softened. Spleen normal. Left kidney weighed seven ounces, was somewhat swollen, and its tissues were slightly flabby. The capsule was thickened and somewhat adherent. The organ was congested and somewhat swollen. Right kidney weighed six ounces, and presented same appearances as the left. Liver was large, swollen, and marked by the ribs. Its surface was mottled with rounded yellowish patches, surrounded by dark-red areolæ. Section showed it to be markedly congested. Its weight was four pounds four ounces. Lungs much congested, the base of the left being anteriorly bound down by old adhesions. The brain was not examined. Examination of the fracture showed it to be ununited, and there was no callus detectable. The periosteum tore easily. On section, the medullary substance of the cavity of the tibia showed marked evidences of inflammation. There was a puffy septum of granulating tissue between the ends of the fragments. Above there was evidence of extravasated blood, and two and

a half inches above the line of fracture there was a small circumscribed medullary abscess. The medullary tissue was inflamed and streaked with red lines.

Through the kindness of Prof. Brinton and Dr. Longstreth, Dr. Wilson was enabled to show several pictures illustrative of osteomyelitis. This was the only case of death from simple fracture recorded at the Pennsylvania Hospital. This disease must be a very rare sequel of simple fracture. It is not necessarily a fatal disease, as the inflammation may become circumscribed, a depot of pus formed, and the destructive processes end there; or a portion or the whole of a bone may die or be removed. It is easy to see how a virulent inflammation going on to suppuration, with no vent to the pus, as in this specimen, could readily give rise to septic poisoning. Dr. Wilson stated that he was indebted to the courtesy of Dr. Longstreth both for the specimen and assistance in its preparation.

Dr. TYSON said that he had seen many cases of osteomyelitis from gunshot injuries during the late war; but he could not recall a case where the medullary canal was encroached upon by a condensing osteitis, as in this specimen.

Dr. NANCREDE related a case of fatal septic trouble following a simple fracture of the thigh, where the starting-point seemed to him to have been a superficial ulceration of the skin, produced by the adhesive plaster. Possibly section of the bone might have revealed an osteomyelitis; but, as the fracture was firmly united, he thought the skin abrasion the starting-point, and related two cases of pyæmia produced by equally trivial causes.

Dr. LONGSTRETH related a case seen by him when a resident physician at the Pennsylvania Hospital. The patient had a fracture of the thigh of three weeks' standing, and was apparently doing well, when chills, sweats, lung-consolidation, etc., ushered in a fatal attack of pyæmia. A post-mortem revealed osteomyelitis and general pyæmic manifestations. A possible explanation of Dr. Wilson's case is that the patient had been on board ship for three weeks after his injury, where the treatment must have been of the crudest description.

Dr. ESKRIDGE called attention to the endocardial trouble found in septic disease, which he had been taught as a student to consider was of an ulcerative form and of fatal prognostic import. He had, however, seen two cases which presented all the symptoms of ulcerated endocarditis, but which had recovered; while in two others, with a similar clinical history, post-mortem examination revealed only a simple non-ulcerative endocarditis.

Dr. SHAKESPEARE asked whether this condensing osteitis might not have been due to a previous syphilitic trouble?

C. B. NANCREDE,
Recorder.

REVIEWS AND BOOK NOTICES.

TRANSACTIONS OF THE AMERICAN GYNÆCOLOGICAL SOCIETY. Volume VII., for the Year 1882. Philadelphia, Pa., Henry C. Lea's Son & Co., 1883.

Considering the long interval between the meeting of the Society and the issue of its Transactions, this volume might be suitably known as the *liber serotinus*. The issue of previous volumes had been provokingly, even vexatiously, delayed, and some were ungracious enough on this account to find fault with the Boston secretary; but now that a New York secretary has been appointed, it is found that the delay is still greater. If New York thus signally fails, where on the boundless continent can hope or help be found?

But let us not quarrel with our bread and butter, even though the waiter has been a long time in bringing it and we have grown much older and most weary with expectation, for the volume is a good one, and, like its predecessors, not less handsome in appearance than valuable in contents.

In the Presidential address, which is by Dr. Emmet, the author departs from the usual custom of presidents of professional associations: instead of an address upon general topics, its wise author considers a special subject,—viz., making “A Button-hole-like Opening in the Female Urethra” for diagnostic and therapeutic purposes. In his concluding remarks Dr. Emmet makes the following statements:

“I have presented a mode of exploration for the female urethra, the advantages of which are not urged upon theoretical grounds, but from actual experience and close observation extending over several years.” . . . “It is claimed that the advantages from the operation for exploration are greater than can be gained by any other method known to the profession, as the whole canal can be fully exposed, and any mode of treatment suggested by the condition of it can be easily applied.”

The operation is done by introducing a block-tin sound, large enough to put the tissues on the stretch, into the urethra, and then cutting through to the canal from the vaginal surface; care must be taken not to carry the incision either so far forward as to injure the orifice of the urethra, or so far backward as to divide the neck of the bladder: where exploration only is desired, the incision may be closed immediately after this is accomplished.

The most important criticism upon Dr. Emmet's address was made by Dr. Skene, whose high authority in all matters pertaining to diseases of the female urethra and bladder no one questions. Dr. Skene asserted that the method is excellent for the diagnosis of urethral polypus or any of the neoplasms, and that there its value ceases; it is very much

inferior, for example, to the endoscope in the diagnosis of ulceration and of fissure.

The Proper Use of Ergot in Obstetrics is the title of the next paper, its author being Dr. Joseph Taber Johnson, of Washington, D.C. Dr. Johnson is quite radical in his views, declaring that he thinks the human race would be better off if ergot were banished from the lying-in room,—an opinion which will hardly be upheld by many in the profession.

Dr. Drysdale, of Philadelphia, is the author of the next paper, *The Ovarian Cell, its Origin and Characteristics*. Here is a paper elaborate, controversial, and yet inconclusive; at least the profession is slow to accept the conclusions of its author. Mr. J. Knowsley Thornton, of London, who was present, in discussing the paper, stated that from his experience the practical value of the Drysdale corpuscle is often at least immaterial. The results of the study of Dr. Garrigues in regard to the microscopic characters of ovarian fluids, are well known as directly antagonizing the statements of the author of this paper. It will not do, however, to ignore the researches of so industrious a man as Dr. Drysdale, researches which have been carried on for so many years, and which include the examination of the fluids from two thousand abdominal cystic tumors. If the Society desires the establishment of the truth in regard to this greatly-controverted matter, it could not do a wiser thing than to refer the subject to a committee of microscopists, giving them two or three years to make their report; let us have some positive knowledge, some fixed conclusions, in place of continued controversy.

Dr. R. Stansbury Sutton, of Pittsburg, contributes a paper entitled *Some Remarks on Ovariectomy, with Special Reference to the Treatment of the Pedicle*. Dr. Sutton gives the various methods of treating the pedicle which have been or are practised by famous operators, refers to the use or the non-use of carbolic acid spray, and states fourteen conditions which he believes lead to success, and sixteen which lead to failure in ovariectomy.

The next paper is by Dr. Fordyce Barker, and is entitled *Leucorrhœa considered in Relation to its Constitutional Causes and Treatment*. In these days, when if there be not too much surgical there certainly is too little medical gynæcology, Dr. Barker's paper is peculiarly valuable. It may be useful for those who are in danger of becoming enamoured of uterine surgery to ponder such sentences as the following from this veteran practitioner, this wise observer: “I have seen leucorrhœa, and various morbid conditions of the os and cervix, disappear by the use of proper hygienic measures, and such treatment as was indicated for the improvement of the general health.” . . . “In very many cases in which leucorrhœa and other uterine disorders have been the consequences of parturition, local treatment is useless, and often positively in-

OLEATES.

These preparations are salts formed by the union of oleic acid with the respective bases indicated. They are designed for external application, and owe their superiority to the well-known penetrative property of oleic acid. Their medicinal action is entirely dependent on their bases, which are quite readily introduced into the circulation when applied epidermically in this form. As a means of securing the constitutional effects of these bases, their application in the form of the oleates offers many advantages, which will be readily appreciated, especially in the treatment of children and in cases of irritability of the stomach.

Although the advantages to be derived from the combination of bases with oleic acid were recognized as early as 1872, the use of these compounds has not become general, and principally because of defects in the pharmaceutical preparation, the original crude method of their preparation not having been improved upon. Within the past year Dr. J. V. Shoemaker, of Philadelphia, has made the subject of the oleates one of especial study and experiment, both from a pharmaceutical and a clinical standpoint. The result has been the production of a number of very eligible compounds, and the discovery of therapeutic properties hitherto unrecognized. We have secured from Dr. Shoemaker full information touching his methods, and are now prepared to furnish oleates of the following metals, which have been found of great value in the affections indicated:

ALUMINIUM.—A valuable astringent, serviceable in eczema, and as a dressing for burns.

ARSENIC.—This preparation contains twenty (20) grains of oleate of arsenic to the ounce, and is employed as a caustic in the treatment of lupus, epithelioma, etc.

BISMUTH.—An excellent emollient application.

COPPER.—For the treatment of ringworm, etc.

IRON.—Readily soluble in the fats, and use-

ful both as a local astringent and as a general tonic.

MERCURY.—Useful as a discutient to inflammatory exudates, and for the constitutional effect of the metal.

LEAD.—A cleanly and efficient substitute for Hebra's Diachylon Ointment.

SILVER.—An excellent application in pruritus and in erysipelas.

ZINC.—An impalpable powder, and of great value in intertrigo (chafing).

OLEATES OF ALKALOIDS.

OUR LIST OF THESE COMPRISES:

Aconitine (2 per cent. of the alkaloid).

Atropine (2 per cent. of the alkaloid).

Morphine (10 per cent. of the alkaloid).

Morphine and Mercury (5 per cent. morphine and 20 per cent. mercuric oxide).

Quinine (25 per cent. of the alkaloid).

Strychnine (2 per cent. of the alkaloid).

Veratrine (10 per cent. of the alkaloid).

OINTMENTS OF OLEATES.

These contain the several metals mentioned above. They are much more cleanly than ointments as ordinarily prepared, and for all the properties of ointments are much to be preferred.

Circulars fully descriptive of the above, and such other information touching the therapy of the oleates as has appeared, will be furnished gratis on application.

PARKE, DAVIS & CO.,

NEW YORK:

Manufacturing Chemists,

60 Maiden Lane and 21 Liberty Street.

DETROIT, MICH.

BOUDAULT'S PEPSINE

THE ONLY PEPSINE USED IN THE HOSPITALS OF PARIS FOR THE LAST 30 YEARS.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the medical profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 1872, 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy every one that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of 4, 8, and 16 ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE.

Formula of Dr. Corvisart.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of 8 ounces.

AGENTS FOR THE UNITED STATES,

E. FOUGERA & CO., New York.

TANRET'S PELLETTIERINE.

FOR THE TREATMENT OF TAPE-WORM (TÆNIA SOLIUM).

This New Tanifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Dr. Dujardin Beaumetz, Member of the Academy of Medicine, and Prof. Laboulbène, in their report to the Society of Therapeutics, have given it their unqualified approval after the most searching experiments. This preparation is pleasant to administer, and if certain preliminaries are observed success will be insured. Sold only in bottles containing one dose.

TANRET'S ERGOTININE.

ALKALOID AND ACTIVE PRINCIPLE OF SPURRED RYE.

This is a well-defined alkaloid that must not be confounded with Ergotine or other extracts. It is given in doses of from $\frac{1}{4}$ to $\frac{1}{2}$ milligramme (1-240th to 1-120th of a grain) in all cases where Ergot is indicated, viz., Flooding, Post Partum Hemorrhages, Metrorrhagia, etc. It is put up in the following forms:

Syrup, containing $\frac{1}{4}$ milligramme to each teaspoonful; Dose, from 1 to 6 teaspoonfuls per day.

Solution, for hypodermic purposes, containing 1 milligramme to each cubic centimetre; Dose, from 3 to 10 drops.

The Institute of France has awarded one of its prizes to Mr. Chas. Tanret for the discovery of these alkaloids.

Tanret's Pelletierine and Ergotinine are only prepared by Mr. Chas. Tanret, Laureate of the Institute of France, 64 Rue du Rempart, Paris.

SOLE AGENTS FOR THE UNITED STATES,

E. FOUGERA & CO., 30 North William Street, New York.

PAMPHLET ON PELLETTIERINE AND ERGOTININE SENT ON APPLICATION.

DR. RABUTEAU'S

(Laureate of the Institute of France)

DRAGÉES, ELIXIR, AND SYRUP OF IRON.

"The experiments made in the hospitals of Paris have demonstrated that Dr. Rabuteau's Dragées, Elixir, and Syrup regenerate the red globules of the blood with a rapidity never observed with the use of the other ferruginous preparations. These results have been proved by the various *Compt-Globules*

"The ferruginous preparations of Dr. Rabuteau do not cause any constipation, and are perfectly tolerated by the weakest persons."—*Gazette des Hôpitaux*.

Dr. Rabuteau's Elixir is prescribed when some difficulty is experienced in swallowing the Dragées; it is especially adapted to weak persons whose digestive functions need strengthening or stimulating.

Dr. Rabuteau's Syrup is especially prepared for children, who take it readily because of its agreeable taste.

A sample of Rabuteau's Dragées will be sent free to any physician mentioning THE PHILADELPHIA MEDICAL TIMES.

Prepared by CLIN & CO., Pharmacists, Paris.

E. FOUGERA & CO., Agents for the United States.

jurious, but a cure results from appropriate constitutional treatment."

The next paper is on *Care of the Perineum*, its author Dr. Theophilus Parvin. The view advocated by the author is that protection of the perineum in the latter part of the second stage of labor is best secured by having the patient lying upon her side, and preventing the exit of the head until the vulvo-vaginal orifice is sufficiently dilated: should rupture occur, the immediate operation is advised, but the usual subsequent tying the knees together rejected.

The Relative Value of Hysterectomy and of the Complete Removal of the Uterine Appendages for the Cure of Uterine Fibroids is the title of an elaborate paper by Mr. Thornton. Mr. Thornton takes the ground that the operation of complete removal of the uterine appendages for fibroid and fibro-cystic tumors of the uterus is indicated in all cases which need the surgeon's aid, as an equally certain cure, and a more conservative and less dangerous operation than that of supra-vaginal hysterectomy. The paper elicited a most interesting discussion, in which Drs. Goodell, Thomas, and Kimball were the chief participants. Dr. Thomas very justly took the position that to expose a woman to the dangers of oöphorectomy or hysterectomy simply because she has a solid fibrous tumor of the uterus is a most unjustifiable procedure, and that the conservative surgeon will avoid any approach to hysterectomy for solid or fibro-cystic tumors of the uterus, unless the life of the patient seems to be in danger on account of the existence of the growth.

The next two papers are on *Electricity in Extra-Uterine Pregnancy*, by Dr. Garrigues, and *The History of Twenty-One Cases of Extra-Uterine Pregnancy*, by Dr. Thomas. The conclusions of the first author, made after a careful study of the subject, are:

"1st. Experience has proved electricity to be an efficacious and safe agent to arrest extra-uterine pregnancy during the first three months, and perhaps the pregnancy in some of the cases had even advanced more or less into the fourth month.

"2d. It seems likely that the same agent might be profitably used at any period of foetal life."

Dr. Thomas takes the following positions: Before the end of the fourth month, destroy the life of the foetus by electricity; if interference be necessary after the fourth month, perform laparotomy, or, if the tumor be low down in the pelvis, elyototomy; if the pregnancy be abdominal, wait the full term of gestation, and deliver by laparotomy, or by elyototomy combined with the forceps or manual delivery; if the full term of pregnancy be passed, and the foetus dead, wait and watch, if it be possible, until nature demonstrates the outlet by which she desires extrusion to be effected, and then aid this effort.

The Influence of the Constant Use of High-Heeled French Shoes upon the Health and Form of the Female, and upon the Relation of the Pelvic Organs, is the title of an interesting paper by Dr. Samuel C. Busey, of Washington. Dr. Busey ably presents the injurious consequences that may result, and gives scientific proof that they ought to occur, from French high-heeled shoes. In the remarks which followed the reading of the paper both Dr. Barker and Dr. Thomas stated that while theoretically Dr. Busey's views were correct, yet they had not found the injury which was to be anticipated from wearing the shoes in question. Dr. Barker seemed to think that the shoe question was one which would be settled by the opinion of men, saying that "women have a sharp instinct, and will so array themselves as to make themselves attractive to the opposite sex." While this statement is generally true, yet sometimes women follow ugly and injurious fashions that are condemned alike by sensible persons, whether male or female; for example, what true admirer of womanly beauty, intellect, and purity does not abhor the hideous hiding of the forehead, animalizing, in almost every case, instead of spiritualizing the expression?

Mechanical Therapeutics of Versions and of Flexions of the Uterus is the title of a long and abundantly-illustrated paper by Dr. Ely Van der Warker, of Syracuse, New York. In the beginning of his paper Dr. Van der Warker says, "The correction of a flexion or version of the uterus mechanically, with certainty, comfort, and safety to the subject, depends, in the first place, upon a few fixed and absolute conditions which cannot be violated. I enumerate them: (a) The limits imposed by uterine mobility; (b) the limits imposed upon the action of pessaries by the vagina; (c) a pessary must be adjusted with proper regard for the safety of the pelvic soft parts; (d) a pessary must be so adjusted as not in any way to retard or arrest the function of any pelvic organ, nerve, or vessel."

After discussing these propositions, the author makes the usual classification of pessaries,—vaginal with external support, those that are solely vaginal, and, third, intra-uterine,—making some original and scientific subdivisions in each class. The whole paper is worthy the close study of any one who attempts to treat uterine diseases, but we have not space for any complete analysis of it.

Dr. J. Collins Warren contributes a paper entitled *A New Method of Operating for the Relief of Rupture of the Perineum through the Sphincter and Rectum*. Dr. Warren says, "The principle of the method described in this article consists in shutting out the rectum entirely by a flap-operation, so that it shall no longer enter as an element to be considered in the healing process. The material of which the flap is composed is that usually cut away by the scissors, and consists of vaginal and

vulvar mucous membrane, and also of a certain amount of cicatricial tissue which is to be found at the margin of the rent. The flap is formed by dissecting the 'butterfly' from within outward, preserving the materials just mentioned in one continuous mass, the pedicle being formed by the entire free margin of the septum, a hinge on which the flap is swung over so as to exclude the rectum from view." Dr. Warren advises the knife rather than the scissors to be used in the dissection. In this operation, of course, no tissue is cut away; it is all utilized. The plan seems so reasonable, and it has proved so successful in the hands of Dr. Warren, that it is well deserving of being followed by others.

Measurements of the Uterine Cavity in Childbed, begun by Dr. Sinclair, are continued by Dr. Richardson; he here presents a fourth and fifth series of one hundred and eight cases each. As no deductions are proposed to be made until the entire number of cases reaches one thousand, it is unnecessary to make other reference to this work at present.

Surgical Operations upon the Pelvic Organs of Pregnant Women is the title of a very able and interesting paper by Dr. Matthew D. Mann, of Buffalo. The following are the author's conclusions:

"1. Pregnancy is not so decidedly a bar to operations on the pelvic organs as is generally supposed. The results, however, vary with the operation and the organ operated upon.

"2. Union of denuded surfaces is the rule, and the cicatricial tissue formed during the earlier months of pregnancy is strong enough to resist the shock of labor at term.

"3. Operations on the vulva involve very little danger either to mother or to child.

"4. Operations on the vagina are likely to cause severe hemorrhages, but are not otherwise dangerous.

"5. Venereal warts and vegetations of large size and non-syphilitic are best treated by removal, whether they occur in the vagina or are confined to the vulva.

"6. Applications of nitrate of silver and astringents of this class may be made with safety to the vagina and cervix. Diffusible poisons, like carbolic acid and iodine, should not be used pure or in strong solutions for such applications.

"7. Operations upon the bladder and urethra are not dangerous, or likely to be followed by abortion.

"8. Operations on the rectum involving the sphincter ani, even if slight in their character, are dangerous.

"9. The operation for vesico-vaginal fistula should not be undertaken during pregnancy, as the dangers of hemorrhage and abortion are considerable.

"10. Plastic operations upon the cervix and perineum may, if necessary, be undertaken in the earlier months of pregnancy with a fair

prospect of success, and with a good chance that the results may not be impaired by labor.

"11. Small polypi of the cervix may best be treated by torsion or strong astringents. If cut, there is some danger of abortion following.

"12. Large polypi may, if causing hemorrhage, be removed at once with a fair chance of good results. If not doing any harm, then removal is best left until near the close of pregnancy.

"13. Cancer of the cervix discovered during pregnancy should, if possible, be removed at once."

Dr. W. H. Baker, of Boston, contributes a paper upon *Hyperæmia of the Vesico-Urethral Membrane*. This paper is quite a practical one, and is illustrated by some chromo-lithographs.

The final paper is *A Memoir of the Late James P. White*, of Buffalo, by Dr. T. G. Thomas. Dr. White was a good man, and Dr. Thomas has not said a word too much in his praise.

The volume is concluded with a list of gynæcological journals and societies, and the usual but most valuable gynæcological index.

GLEANINGS FROM EXCHANGES.

A RAPIDLY FATAL CASE OF ARSENICAL POISONING.—The following case presents several points of interest, the chief, however, being the rapidity with which a fatal result ensued. It was reported by David W. Finlay, M.D., in the London *Lancet*.

Richard H., aged 51 years, a man in moderate health, although not robust, swallowed by mistake, at 8.30 P.M. on February 27 last, nine drachms of a preparation for softening the skin of the hands, supposed to consist chiefly of glycerin, which was contained in a small flask-shaped spirit-bottle. He was seized with a feeling of faintness and collapse, and slight epigastric pain. He was brought without much delay to the Middlesex Hospital, arriving there about nine o'clock; and it was stated that he had not vomited. His skin was cold, and his face bedewed with clammy sweat; pulse slow and very feeble; respiration shallow; pupils moderately dilated, but acting to light. He presented generally the appearance of collapse, and complained of headache and pain at the epigastrium, with a sense of constriction across the chest. He was quite conscious, and kept spitting to clear his mouth of viscid mucus. An emetic of mustard-and-water was immediately administered, but did not induce vomiting, and the stomach-pump was then used, the stomach being well washed out. The matter removed from the stomach appeared to consist almost entirely of the mustard-and-water which had been given as an emetic.

Some brandy was then administered, and he was removed to the ward and put to bed between warm blankets, hot bottles being also applied. Notwithstanding, he speedily became pulseless, and, although stimulants were freely given, he rapidly sank, and died at half-past nine o'clock, one hour after swallowing the fatal dose.

At the post-mortem examination made by Dr. Fowler, the mucous membrane of the larynx was found moderately congested; the trachea was brightly injected throughout, and, with the larger bronchi, contained some very viscid mucus. The lungs were emphysematous and engorged. The right cavities of the heart contained some fluid blood and clots, the left were contracted and nearly empty; the valves and muscular substance were normal, but the endocardium of the left ventricle showed numerous ecchymoses. The liver and kidneys were congested, the spleen normal. The stomach contained about six ounces of turbid fluid, consisting apparently of brandy, mustard in solution, and viscid mucus. The mucous membrane was intensely injected; there were also a very few small ecchymoses, but no erosion of mucous membrane. The duodenum and jejunum contained pale pulaceous matter; the contents of the ileum and colon were brown and semi-solid. The bladder was contracted. It was, of course, sufficiently obvious that death was due to poison, but there seemed nothing either in the symptoms or post-mortem appearances to point conclusively to the particular poison, and hence at the inquest which was held an analysis of the stomach and its contents was ordered. This resulted in the detection of arsenious acid in large quantity, both in the matter removed from the stomach at the post-mortem examination, in the tissues themselves, and in the small quantity of fluid left in the bottle from which the unfortunate man had swallowed the poison.

What remained of the latter, together with the quantity which the bottle was known to contain by a mark left on it in consequence of the length of time the solution had remained in it undisturbed, supplied data for an estimation of the quantity of the fatal dose. The former, amounting to half a drachm, converted into sulphide, was found to represent exactly a decigramme, or rather more than one grain and a half, of arsenious acid, and, the total quantity of liquid in the bottle being nine drachms, would equal twenty-seven grains and three-quarters. Deducting from this total the quantity left in the bottle, the conclusion is reached that upwards of twenty-six grains had been swallowed. The fatal period is one of the shortest on record; indeed, I am aware of only one instance in which a more rapidly fatal result ensued. This occurred in the case of a youth aged 17, who was stated to have died within twenty minutes after a large dose, the symptoms being of a

tetanic character. Reference is made to it in Taylor's "Principles and Practice of Medical Jurisprudence," vol. i. page 256, second edition, but details are wanting. In the present case, the largeness of the dose, its state in solution, and the comparatively empty condition of the stomach, all of which would favor rapid absorption, sufficiently account for the speedy death. The same considerations also account for the somewhat abnormal character of the symptoms, those referable to the stomach being slightly marked, while collapse was profound and conspicuous. Such cases lend support to the opinions expressed by M. Vryens, whose experiments and the conclusions drawn therefrom are set forth in the "Archives de Physiologie," vol. viii., 1881. The latter are to the effect that the fundamental character of arsenical poisoning consists in a perversion of the entire nervous system, and that the pneumogastric, sympathetic, and vaso-motor nerves especially are paralyzed or reduced to a state of paresis.

MISCELLANY.

PHYSICIANS AND DRUGGISTS.—The following admirable series of rules have been submitted for the adoption of pharmacists and physicians in Cincinnati:

First.—Pharmacists shall not prescribe medicine for diseases.

Second.—Pharmacists shall not too frequently fill prescriptions which might lead to disease or vicious habits.

Third.—Pharmacists shall only supply medicines on prescriptions or where the complaint is stated by a customer to be one dangerous to life.

Fourth.—The right to refill prescriptions, when presented by the person to whom they were issued by the physician, is acknowledged.

Fifth.—Physicians should not dispense medicines, except in cases of emergency, nor prescribe proprietary, secret, or copyright medicines.

Sixth.—The prescription when in the hands of the pharmacist and filled shall be the latter's property, as it may be necessary for his protection.

Seventh.—The use of prescription-blanks by physicians, with the address of any individual pharmacist on them, is liable to misconstruction, and shall be discontinued.

Eighth.—The evils arising from the wholesale use of patent medicines are recognized, and their use discountenanced.

Ninth.—A Board of Arbitration consisting of five physicians and five druggists shall be appointed, who shall subscribe to these rules. This board shall hear all complaints against any subscriber to these rules for their violation, and shall decide disputes.

THE NEW YORK STATE MEDICAL SOCIETY.—From telegraphic dispatches from Albany just received, it appears that the New York State Society, in adopting a course which separated it from the American Medical Association and isolated it from the profession throughout the country, has finally alienated some of its oldest and most respected members. Without making comparisons, which are invidious, we would simply point to the names and relative position in the profession of the leaders of the two great parties in the controversy to show which better deserves the confidence and respect of the profession and the community. In New York City it was found necessary to form a new county medical society, which is in affiliation with the other county medical societies throughout the country. If the apparent necessity for a similar course has been forced upon the very respectable minority in attendance upon the meeting (but representing in reality the majority of the profession in New York State) we regret it, but consider it preferable to the unseemly wrangling which has disturbed the harmony of the last few meetings of this association. When the specialists find that they will have to go into a corner and flock by themselves, they may have cause to repent of their action and regret their loss of prestige in the profession. An account of this meeting will appear in our next issue.

THE PHILADELPHIA NEUROLOGICAL SOCIETY.—On Monday evening, January 28, 1884, a meeting of physicians of Philadelphia and vicinity who are specially interested in nervous and mental diseases was held at the hall of the College of Physicians, Thirteenth and Locust Streets, and organized the Philadelphia Neurological Society. The society will hold stated meetings on the fourth Monday of every month. The officers are:

President.—Dr. S. Weir Mitchell.

Vice-Presidents.—Drs. Charles K. Mills and Isaac N. Kerlin.

Secretary and Treasurer.—Dr. James Hendrie Lloyd.

Council.—Drs. S. Preston Jones, Wharton Sinkler, and J. T. Eskridge.

THE PHILADELPHIA CLINICAL SOCIETY, late the Northern Medical Association, reorganized January 25 at the College of Physicians. A large number of new members were enrolled, and the following officers elected for the ensuing year: President, Dr. Henry Beates, Jr.; first vice-president, Dr. E. E. Montgomery; second vice-president, Dr. Hannah T. Croasdale; corresponding secretary, Dr. J. E. Richardson; recording secretary, Dr. J. G. Heilman; reporting secretary, Dr. G. Betton Massey; treasurer, Dr. L. Brewer Hall; censors, Drs. A. S. Barton, S. N. Troth, Albert H. Smith, James B. Walker, and Henry Rihl. To this Society women physicians are eligible, as may be seen from the list of officers.

The *Journal of the American Medical Association* has successfully entered upon its second volume, and shows marked improvement in proof-reading; but somebody is still responsible for a good deal of uncertainty about French spelling and accents ("*Annals de la Société Medico-Chirurgicale de Liege*," for example).

THE NEW YORK POST-GRADUATE MEDICAL SCHOOL has been so successful that it will move to a new building on or about February 1, 1884, which will enable it to give hospital advantages to its matriculates. The new building is very large, being five stories high and having a front of ninety-five feet. The new announcement gives a list of one hundred and forty physicians, who were matriculates for the year ending November 1, 1883.

THE PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES has had seventy-two paying members in its different classes during the past term. During the nine and a half months from its opening there were treated three thousand three hundred and one new patients.

NOTES AND QUERIES.

ELISHA HARRIS, M.D.

Dr. Elisha Harris, Secretary of the State Board of Health of New York, died at Albany on the 31st ult., from peritonitis, after a week's illness. He was graduated at the College of Physicians and Surgeons in New York in 1849, and subsequently devoted himself to State medicine. He was secretary of the American Public Health Association from the time of its organization, and was very active in aiding the Sanitary Commission during the war. From 1866 to 1876 he was Sanitary Superintendent and Registrar of Vital Statistics in New York City. In 1881, becoming a member of the State Board of Health, he became very active in organizing and perfecting its work. He was known as a writer upon vital statistics and sanitary matters, being a valued contributor to the Proceedings of the American Public Health Association. He died in the 60th year of his age.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM JANUARY 26, 1884, TO FEBRUARY 2, 1884.

ALEXANDER, CHARLES T., MAJOR AND SURGEON.—So much of Paragraph 1, S. O. 211, September 14, 1883, as directs him to report in person to the commanding general Department of the Missouri, for duty, is revoked, and he will, upon the expiration of his present leave of absence, proceed to St. Louis, Mo., and assume duty as attending surgeon and examiner of recruits in that city. Paragraph 1, S. O. 21, A. G. O., January 25, 1884.

ELBREY, FREDERICK W., CAPTAIN AND ASSISTANT-SURGEON.—Present leave of absence extended six months. Paragraph 9, S. O. 24, A. G. O., January 25, 1884.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY FROM JANUARY 19, 1884, TO FEBRUARY 2, 1884.

P. A. Surgeon ROBERT WHITING detached from the hospital Norfolk, Va., and ordered to the "Colorado."

Assistant-Surgeon H. B. FITTS detached from the "Jamestown" and ordered to the coast survey steamer "Gedney."

P. A. Surgeon F. ANDERSON granted leave of absence for six months.

P. A. Surgeon S. W. BATTLE detached from the U.S. steamer "Gedney" and placed on sick leave.

PHILADELPHIA, FEBRUARY 23, 1884.

ORIGINAL LECTURES.

CLINICAL LECTURE ON PHTHISIS PULMONALIS.

Delivered at the Philadelphia Hospital

BY JAMES TYSON, M.D.,

One of the Physicians to the Hospital, and Professor of
General Pathology and Morbid Anatomy in the University
of Pennsylvania.

Reported by WILLIAM H. MORRISON, M.D.

GENTLEMEN,—I wish to-day to call attention to a series of cases the discovery of a cure for which will certainly be rewarded by immortality. I refer to phthisis pulmonalis, or, as it is commonly called, consumption. It is not possible to bring before you a class of cases the interest of which is greater, or the practical importance of a correct understanding of which is more obvious. Up to the present time, it is to be regretted that we have found no specific remedy for this affection. I do not mean to say that advance has not been made in the treatment of phthisis, for this is not the case. At the same time, we are, in a large majority of cases at least, after a certain stage has been reached, utterly powerless to influence the disease favorably. I desire in the course of this lecture, if time permits, to illustrate at least three stages, and to endeavor to give you some insight into the pathology of the process, as it is understood to-day, on a correct notion of which will be based the successful treatment, if such is ever discovered; also to lay before you the treatment which I think is most useful.

The first patient is 32 years of age, unmarried, a driver and loader of wagons. He was admitted to the hospital on November 6, 1883. He knows nothing of his grandparents, but his parents are both living and well. He has brothers who are also in good health. This we should call a good family history. He had malarial fever when fifteen years old. Since then he has had almost no sickness. The present attack began about October 1, 1883, when, after exposure, he acquired a cough, which was accompanied by considerable expectoration. Shortly afterwards hemorrhage appeared, which continued at intervals for over a month.

At times he would have three or four hemorrhages in a day, sometimes losing as much as a gill of blood. He gradually lost flesh and strength. He also suffered from shortness of breath.

Such a history of course suggests a physical examination of the chest. This I shall now make before you. It is desirable that all starched shirts should be removed; but, on the other hand, it is not necessary, or even desirable, that a person to be thus examined should be completely stripped. A thin undershirt is the most suitable medium through which to make an examination, except for inspection, for which the chest should be bared.

Inspection here reveals no striking difference in the degree of movement on the two sides, nor is there retraction of the chest-wall on one side compared with the other.

Now as to the results of *percussion*. First, on the clavicle. On the left side there is evident flatness in this situation. Above the clavicle there is impaired resonance. Below the clavicle the resonance is impaired, and this impairment of resonance continues downward as low as the fourth rib. In the left axilla the percussion-note is good. Let us now examine the back of the left chest. The thick walls of the posterior part of the chest will of course give less resonance than the thin anterior walls. Still, we find a decided difference in percussing above the spine of the scapula on the two sides. There is marked flatness on the left side, and the resonance is impaired as low as the angle of the scapula. On the right side, both in front and behind, the resonance is good.

I shall now *auscultate* the chest. In practising auscultation, the direct application of the ear is more satisfactory than the mediate method by a stethoscope. It is only when we desire to localize sounds or examine the heart that a stethoscope is of especial advantage. I find that the respiratory murmur is feeble both in inspiration and in expiration and on both sides, but more particularly on the left, below the clavicle. This is somewhat different from what we should have expected, but I shall try to explain the cause of this later on. There is the same feebleness of respiration posteriorly.

As to *vocal fremitus*, I can scarcely detect any difference in the amount of vibra-

tion, which is feeble on both sides, below the clavicles. In point of fact, the vocal fremitus is possibly a little more distinct on the right than on the left side. These physical signs are not precisely what I expected to find, and make the case less simple than I should desire for the purpose of illustration.

But what do these physical signs teach us? We have found decided impairment of resonance on the left side, both anteriorly and posteriorly, which means that the normal vesicular structure of the lung has in some way been substituted by solid material. The feebleness of respiration upon the left side, as compared with the right side, may be due in the early stages of the disease to the interference with the entrance of air into the vesicles, thus preventing their dilatation and the respiratory murmur incident to this act in health. Or it may be due to the interposition of a thickened pleura. There is one sign which, at first thought, is inconsistent with the view of simple consolidation; that is, the vocal fremitus is slightly diminished, rather than increased, as we might expect. This diminished fremitus is also probably due to a thickened pleura. There has probably been a plastic pleurisy, which has caused this thickening, this interference with the transmission of vibrations. Such thickening also interferes with the conduction of the respiratory sounds. More frequently there is, with dulness on percussion, increased vocal fremitus and bronchial breathing, or, where the vesicular element of the respiratory sound is still present, there is a roughening of the normal respiratory sound with prolonged expiration, known as broncho-vesicular breathing. This is not present in this case.

I believe, however, that there is a process of consolidation going on in the left lung, and that it is a phthisical process. What is the nature of this solid material which has been deposited? You will probably answer that it is tubercular. The answer is correct, but may be met with another question, What is tubercular material? The older views made it a special substance poured out from the blood into the air-vesicles. To-day it is mainly regarded as inflammatory. I certainly think that the tubercular process is inflammatory, but the product is a specific inflammatory new formation, because it is due to a specific poison. That is a specific in-

flammation which results from a specific cause, distinct and separate from the ordinary causes of inflammation. Thus, we have syphilitic, tubercular, and scrofulous inflammations. All these are specific, because they are produced by causes distinct from those of ordinary inflammation. These causes of inflammation occasion products which are more or less peculiar.

There is every degree in the distinctiveness of this tubercular process, from that in which it is readily recognized by its local peculiarities to that in which it is barely distinguishable.

As to the specific agent which is responsible for it, views are not altogether settled, and it would not be profitable to discuss them at too great length. According to some it is a special virus, while according to another view the phenomena are the result of a peculiarity of the individual, either inherited or acquired, as a result of which inflammation in the lungs tends to take on this character. Usually, when a person in health has bronchitis, the cough and expectoration gradually diminish, and the inflammation passes away in a short time. In other individuals the cough hangs on, and the expectoration does not diminish, but is peculiarly thick and inspissated. Sooner or later, in such a case, a feverish condition manifests itself, the cough and expectoration grow worse, and shortness of breath appears. On examining the chest, impairment of resonance is found, as in this patient. The first cough is the result of bronchitis; the later cough is due partly to bronchitis and partly to irritation from the tubercular deposit.

If the lung were examined in the incipient stage of phthisis, the evidences of bronchitis or inflammation of the mucous lining of the bronchi would be first found. After this has existed for a certain length of time there is infiltration of the walls of the air-vesicles, and particularly at the angles of the vesicles. These are filled up with the inflammatory new formation, which is tubercular, and which may present the microscopical characteristics, more or less distinctive, of tubercle. With this, however, we have nothing to do to-day, but shall confine ourselves to the clinical aspects of the disease. Nor shall we discuss the infectious theory of tuberculosis, or have anything to say at present as to its relations to the *bacillus tuberculosis*, about which so much is being said and written.

How should such a deposit affect the physical signs? In the first place, in the beginning, there is an impediment to the entrance of air, and, as a result, feebleness of respiration. This feebleness of respiration appears before the broncho-vesicular breathing. There is also impairment of resonance, on account of the presence of solid matter.

From this initial stage there are two ways in which the tubercular process may extend, one which is peripheral or centrifugal, and a second which is central or centripetal. In the first, or peripheral, mode of extension the vesicles become more and more involved, until large areas of vesicular structure are substituted by the solid tubercular matter. Remember, however, that the deposit is not directly into the cavity of the vesicle. It takes place first in the walls of the vesicles, and as these become thicker they encroach more and more upon the lumen of the vesicles and infundibula, until they are converted into a solid mass, which gives rise to the dulness on percussion, and the bronchial breathing. The air is shut out from the air-vesicles, and the only sound heard is that produced in the bronchi, which is conducted to the ear by the solidified lung. This mode of extension causes the rapid forms of phthisis, which terminate in from six weeks to one year.

The second mode of extension is centripetal. In this form the disease travels towards the root of the lung along the bronchi, the walls of which become infiltrated. The vesicles are thus left comparatively intact, while there is peri-bronchial infiltration with tubercular matter. This mode of development is less rapid than the peripheral, and gives rise to the cases of chronic phthisis which last from two to twelve years. In the centrifugal process the essential structure of the lung is affected, but in the centripetal the cells are less involved, while the walls of the bronchi are largely implicated. Hence the longer duration of the latter.

There is no consumption which is not preceded by bronchitis, except, probably, acute general miliary tuberculosis. Not very long ago it was thought that bronchitis and tuberculosis were quite independent of each other; but to-day we are satisfied that every consumption, with the exception just mentioned, begins with bronchitis. It is this which is the proximate

cause of the tubercular process, although it must be superimposed upon the tendency above referred to.

The second patient whom I show you illustrates the effects of the infiltration of large areas with this tuberculous matter; as a result of which there is flatness on percussion over a large portion of the right side anteriorly. Instead of feebleness of respiration and diminished vocal fremitus, there is bronchial breathing and increased vocal fremitus.

The next patient illustrates the third stage of the disease, the formation of cavities. As the infiltration goes on, and larger areas of the lung-tissue are involved, the tubercular matter finds difficulty in being properly nourished, and, as a result, dies. The central parts, as a rule, die first. The cells which make up the deposit undergo fatty degeneration, softening, and liquefaction. In typical cases, as soon as the area of consolidation is large enough to interfere with the proper nourishment of the inflammatory mass, it dies, softens, and liquefies, causing a cavity. This does not always take place in the same way. Softening usually begins when the cheesy tubercular mass reaches half an inch to an inch in diameter. The softened interior of the deposit must communicate with a bronchial tube before the signs of a cavity manifest themselves. Sometimes the softening begins with ulceration of the mucous membrane of a bronchial tube, the ulcer grows larger, the mass is brought into communication with the air; it softens, breaks down, and is carried away in the expectoration.

As stated, the case now presented illustrates the softening process. The resonance over a cavity may be impaired. This is due to the existence of consolidated lung-tissue around the cavity. If the vomica is large enough, the resonance will be tympanitic, and sometimes the cracked-pot sound, which is diagnostic of a cavity, may be developed. On the left side of this man's chest we get tympanitic resonance. In order to get tympany it is necessary to percuss heavily. On auscultation, I hear crackling at the left apex, produced by air passing into softened matter.

According as the disease is rapid or slow these stages are reached sooner or later. For instance, the sickness of the first patient dates back to the 1st of October, 1883; that of the second began

three years ago; while in the third man the disease began two years ago. While the general statement that the more advanced the disease the longer it has lasted is true, yet its progress is more rapid in some cases than in others.

The hour has so nearly expired that I shall have but little time to devote to the consideration of the treatment; but I shall do what I can. The important point to remember in connection with the treatment of consumption is that it is an inflammation. It is true that it is a specific inflammation, and on that account more difficult to treat. Some forms of specific inflammation are easily treated, because we have specific remedies for them; syphilitic inflammation is one of this kind, because we have in iodide of potassium and mercury specifics for this disease. Some day we may discover a specific remedy for the specific inflammation of consumption,—a remedy which will give us the same power over that disease which we now possess over syphilis. Until such specific has been found, we must treat the disease as we should any other inflammation. As this is not a sthenic inflammation, we would, of course, not bleed; but we would use that which is found to be so useful in other forms of chronic inflammation,—namely, counter-irritation. To my mind, the first rational treatment in cases of consumption is counter-irritation. This may be done in various ways. If you wish to do it gently and not alarm the patient, mustard might be employed, or iodine or croton-oil may be used. The best method is, I think, the application of a blister over the consolidated lung. It is the best remedy not only for the inflammation, but for the relief of the worst symptom of the disease. The very best cough-medicine, and often the only one which will accomplish the result, is a blister. We have now in our wards a case of consumption in which the cough was most troublesome for six or eight weeks, and cough-medicines of all kinds had failed; but in twenty-four hours the symptom was relieved by a blister.

These patients are always run down. Their reparative powers are poor, and it is necessary to employ the so-called supporting treatment. Every case of consumption which can bear it should take cod-liver oil. There is nothing which approaches nearer a specific remedy for this

disease than does cod-liver oil. It does good in many cases, although not all are benefited by it, and some cannot take it in any form. Where it cannot be used, cream or rich milk should be substituted for it. In addition, the patient should have the most favorable hygienic surroundings which it is possible to give him. So far as certain so-called specific remedies, such as the hypophosphites and the like, are concerned, I must say that I have never seen any benefit whatever from their use. Counter-irritation, cod-liver oil, nutritive food, and correct hygiene are the most successful remedies.

If the cough is not relieved by a blister, it may be necessary to give some form of cough-medicine. It unfortunately happens that the remedies which are useful in allaying the cough are generally those which derange the stomach. In cough-medicines for phthisis it is necessary to give opium in some form. In giving morphia for this purpose, it is often better to give one large dose than a number of smaller ones. This, however, often deranges the stomach and makes it impossible for the patient to take that nutritious food which is absolutely necessary to the cure of phthisis. Where there is a large amount of expectoration, a stimulant expectorant, as the carbonate or chloride of ammonium, should be given to aid in the bringing up of the secretion. A stimulant expectorant of great value is whiskey. A half an ounce of whiskey is often of great service in causing contraction of the muscles of the small bronchi and forcing up the expectoration. It is to be remembered that a certain amount of cough is necessary in phthisis where there is softening and accumulation in the bronchial tubes, in order that the secretion may be removed. If the patient cannot cough he will suffocate.

Another important matter, which should perhaps have preceded what I have said about the treatment of actual phthisis, is the treatment of the bronchitis which precedes the development of phthisis. I have already said that all cases of consumption are preceded by bronchitis. This bronchitis should be treated vigorously, and, if the cough continues, do not be afraid to put a blister over the lung. If these patients are carefully and actively treated, the number of cases of phthisis will, I think, be greatly diminished.

ORIGINAL COMMUNICATIONS.

THE BACILLUS TUBERCULOSIS AND THE ETIOLOGY OF TUBERCULOSIS.—IS CONSUMPTION CONTAGIOUS?

SECOND COMMUNICATION.

*Read before the Philadelphia County Medical Society,
November 14, 1883,*

BY H. F. FORMAD, B.M., M.D.,

Lecturer on Experimental Pathology and Demonstrator of Morbid Anatomy in the University of Pennsylvania; Mütter Lecturer in the College of Physicians of Philadelphia.

(Continued from page 345.)

II.—THE PREDISPOSITION.

HAVING shown that for the production of tuberculosis we need a special soil, and that the irritant is only of secondary significance, some inquiry into the nature of this soil is necessary.

The question of the predisposition to tuberculosis, as it stands at present, must be considered from three aspects:

1. The clinical aspect.
2. The anatomical aspect.
3. The bacteridian or parasitic aspect.

The consideration of the clinical aspect of the predisposition to tuberculosis is invaluable, as it rests mainly on actual observation, on demonstrated clinical facts, and on conclusions drawn from statistics.

From time immemorial, a clinically well-defined condition of the system, known as the strumous diathesis in its various forms, has been recognized. This condition will be considered later on.

There are a number of ailments which, from the experience of clinicians, are known to have a great, direct or indirect, influence in the development of general tuberculosis and pulmonary phthisis, or are known to create conditions of the system that predispose it to this malady. Such are syphilis, inflammation of serous membranes, bronchitis, croupous pneumonia, diabetes, the exanthemata (especially measles and typhoid fever), deformities of the skeleton, rickets, cerebral and spinal diseases of various kinds, dyspepsia, the puerperal state, uterine diseases, prolonged nursing of children, onanism, change of climate, continuous loss of sleep, distress, etc.

That exhaustion, exposure, deprivation of food, and other hardships of campaign-life, etc., are prominent etiological factors in the production of pulmonary consump-

tion is learned from the accounts of military surgeons, who observe among young, robust soldiers a remarkable increase in the morbidity and the mortality of phthisis during and immediately after the close of a war. Such observations have been made in the Franco-Prussian and Turko-Russian campaigns. The fact that consumptive soldiers are not allowed to enter upon a campaign (certainly not in Germany and Russia) excludes here the probability of contagion.

Statistics also show the remarkable prevalence of phthisis in persons of certain occupations, such as stone-cutters, miners, cigar-makers, weavers, telegraph-operators, book-keepers, and persons engaged in certain other occupations of a more or less sedentary nature. It is more natural to suppose that the disease, or the predisposition to it, is created by the character and the conditions of the occupation, than that a contagion should affect preferably shoemakers, miners, or soldiers in the battle-field. Again, in most phthisical patients the beginning of the disease can plainly be attributed to an exposure, to "a cold."

On the other hand, there are pathological conditions or diseases which appear to prevent the development of phthisis and tuberculosis in general. It is an established clinical fact that phthisis is extremely rarely, if ever, associated with mitral heart-disease; and, from my own observations, I believe that phthisis is rarely coincident with tumors. For the latter circumstance I can offer no explanation; nor is there any statement to this effect in literature. Rindfleisch has suggested that heart-disease prevents the development of phthisis by inducing repeated slow congestions of the lungs, these congestions producing an overgrowth of the muscular tissue of the bronchioles and air-vesicles, which thus gains strength for repelling the exudates following inflammation.

If tuberculosis were dependent upon a contagium for its development, neither heart-disease nor tumor-growth, nor any condition of the organism, could ever prevent its occurrence.

All the clinical facts above referred to prove definitely the necessity for a predisposition for the development of tubercular disease, and militate against the necessity of a contagium.

The anatomical aspect of the question—the morphology of the soil in which tubercle develops—is the most important aspect.

Beneke* tries to explain the disposition to tuberculosis by a disproportion between the size of the heart and blood-vessels and other organs to the bulk of the body.

Schottelius† made recently some interesting observations concerning the mode of termination of the smallest bronchioles and their relation to the lung-acini in different animals. He found that in the carnivora the entrance of the bronchioles into the acini presented very small apertures, so that the air-vesicles were not easily accessible to irritants; while in the herbivora the terminal bronchial terminations were quite wide, thus permitting the free entrance of irritants. He states that in man the bronchial terminations congenitally approach sometimes those of the carnivora, and sometimes those of the herbivora. In the latter type he believes he has found an anatomical explanation for the predisposition in some individuals to pulmonary tuberculosis.‡ Weigert, of Leipsic (one of the most enthusiastic germ-theorists), properly remarks upon the observation of Schottelius, that it does not explain the predisposition, as the same animals will react upon the introduction of the “poison of tuberculosis” into any other part of the body, where the bronchials do not come into play.

My own studies upon the minute anatomy of the tissues of man and of animals predisposed to tuberculosis extended over a large amount of material, and gave results which, to my mind, satisfactorily explained this condition. These results I announced at a meeting of this Society in October, 1882.

The anatomical peculiarity observed in either man or animals, whether inherited or acquired, I first showed to be, briefly stated, as follows: all the tissues of the body approach somewhat an embryonal type; they are peculiarly rich in nuclei and young cells, and the lymph-spaces of the connective tissues are narrower, fewer in number, and show a great many more cellular elements in the scrofulous than in

the non-scrofulous. So far, subsequent observations of others agree with mine. Objections are raised only as to the direct relation between these structural peculiarities and tuberculosis. Here I must state that I only suggested, and never asserted, the necessity of such a relation. It is quite possible that there are some other and more striking peculiarities in the morphology of scrofulous animals yet undiscovered. This much I can, however, reassert to-day: that tuberculosis usually ensues when a simple inflammation is set up by any kind of injury, in animals with the structural peculiarity which I have described; but that tuberculosis cannot be produced in animals that do not have this structural peculiarity, so far as my experiments show, unless the injury is inflicted upon serous membranes.

For the details of my researches in this direction I must refer to my first paper upon this subject.§

Koch asserts that the structural peculiarities of the tissues which I described can have no etiological relation to tuberculosis, because an animal not possessed of such tissue-peculiarity—the cat—is easily inoculable by tuberculous material. Here I must differ from Koch, as in my experience with cats this is not the case; and, again, Koch brings no proof for his assertion, and I am unaware that he or anybody else produced tuberculosis in a cat, except by inoculation into some serous cavity. That inoculations into serous membranes prove nothing for tuberculosis, as I have shown conclusively, Koch still seems to fail to see. But here is a way in which cats may become tuberculous with or without the bacillus. In one instance we kept one of the cats in a close box, *deprived* of liberty, with good air, the comforts of life, motion, and sufficient food; she also had been inoculated with diphtheritic material eight months previously, but had recovered. After the lapse of a year the cat was set free, but was accidentally killed, and was found to be affected by general tuberculosis in a high degree.

This, in my opinion, corresponds fully to the conditions in which a healthy young woman is placed, and finally becomes scrofulous, and then tuberculous, from a simple cold, after being the faithful

* Die erste Ueberwinterung in Norderney, Norden, 1882.

† Virchow's Archiv, vol. xci., 1883.

‡ The method of investigating this condition is not without interest. The vesicular structure of the lung was injected, through the bronchi, with a resinous melted mass, which, on cooling, presented moulds of the bronchioles, in connection with their characteristic infundibula and acini.

§ Phila. Med. Times, vol. xiii. p. 109.

nurse for a couple of years of a consumptive husband.

On the other hand, there is full reason to believe, as it is in accordance with experience, that young scrofulous persons, under proper conditions, may become normal individuals,—*i.e.*, may lose or outgrow the predisposition to tuberculosis. (I have dwelt upon this in my first communication on this subject.)

The scrofulous habit, and consequently also phthisis, may skip a generation, and does not invariably embrace all members of a family. It has been observed that parents may have at first healthy children without any vice, who grow up well, and subsequently the same parents, without being phthisical (but perhaps otherwise becoming deficient in health), may have other children that exhibit a full scrofulous habit. But even the reverse has been observed.

It would be highly desirable if physiologists would furnish some experimental observations on the circulation of the plasma in the lymph-spaces. This is, to my mind, a circulation or movement of vital juices in the tissues, which, for the well-being of the individual, is of importance next to that of the blood. These important channels, the lymph-spaces, are known to regulate the blood-pressure, carry and breed (white blood-corpuscles) food for the tissues, lubricate tissues, and relieve the body if any of its parts are damaged by injury of any character, of inflammatory exudates, dropsy, etc. These channels are nearly blocked up, nearly useless, in the *scrofulous*, and hence cannot perform their functions, thus modifying materially the condition and the fate of the individual in case of disease.

The term "*scrofulous*," which I retain for describing the above-stated anatomical peculiarity of animals and individuals, is as good as any other term; moreover, it is known by all as designating the "predisposition" to tuberculosis. Scrofulosis should be called a *condition*, and not a disease, as it has its hereditary and widely-distributed type (a natural one) in man, and its homologue in some normal animals (rabbit, guinea-pig, etc.). It must be remembered that the scrofulous individual acquires certain lesions, such as enlargements of lymphatic glands, cold abscesses, caries, long-standing catarrhs of various kinds, skin-eruption, and certain deformi-

ties of bones, only under the influence of injuries, or of the same agencies which in the non-scrofulous individual lead to transient and curable affections.

Virchow designates simple, permanent enlargement (hyperplasia) of lymphatic glands, with or without cheesy change, as "*scrofulous*," in contradistinction to "*tuberculous*" lymphatic glands, which contain miliary tubercle nodes (heteroplasia), and which also undergo cheesy change.

There is nothing called "*scrofulous*" or "*scrofulosis*" by some which by others is not also called "*tubercle*" or "*tuberculosis*." There are, strictly speaking, no scrofulous products, but only tuberculous products. The traditional term "*scrofulosis*" is variously used and interpreted, although it is not evident that any one means by it anything anatomically well defined.

Others take matters easier, calling everything *tuberculous* that contains tubercle-bacilli, and calling scrofulous all cheesy matters in which bacilli are absent.

There is still a third aspect of this question,—*viz.*, the parasitic or bacillary theory of the predisposition to tuberculosis. As I mentioned in the earlier part of this paper, Baumgarten, Marschant, and several others recently brought forward the view that not only tuberculosis but even the predisposition to tuberculosis is to be explained by the susceptibility of an individual to bacilli. Under this hypothesis, the inherited scrofulous tendency in individuals is created through the mediation of the bacilli. It is supposed that the bacilli or their spores may be conveyed to the ovum by the organism of the mother, or in utero by the spermatozooids of the father. Furthermore, they say, inheritance is to be explained in no other way than by a bacillary infection of the infant through the milk of the nursing mother, and by subsequent living together of children and phthisical parents. We may exclude this view altogether from consideration, as it has not been proved. Besides, it is not in accordance with facts from observation. It is as contrary to biological laws to accuse parasites of the transmission of a predisposition to tuberculosis as it would be for that of epilepsy. Hence we may dispose of this view as an unfounded, absurd hypothesis.

I am not opposed to the germ-theory of disease where it has its well-founded and proper application. Bacteridian studies

have contributed largely to our knowledge of a certain class of pathological processes and lesions. But misinterpretations of the significance of bacteria, bacillary speculations without occasion for them and without any proper application to the subject, are a check to the progress of medical science. The questions of the predisposition to, and the causation of, tuberculosis demand a great deal more of solid pathologico-anatomical and experimental studies; they can by no means be regarded as settled, and least of all through the discovery of a bacillus inhabiting necrotic tubercular tissues.

III.—TUBERCULOSIS, WITHOUT PREDISPOSITION, DUE TO INFLAMMATION OF SEROUS MEMBRANES.

For some years I have felt much interested in the question whether or not simple inflammation of serous membranes could lead to tuberculosis in the non-scrofulous, that is, in persons who have no family history of tubercular disease; and I would like to ask the opinion of the members of the Society upon this question. It is well known that there may be primary tuberculosis of serous membranes, producing secondary inflammations; and, on the other hand, tuberculosis secondary to adhesive pleurisy or peritonitis is also common in serous membranes. The general belief, however, is that whenever tubercular disease in either case occurs, if not secondary to phthisis or tubercular disease elsewhere, a strumous or scrofulous condition is required.

Traumatic injuries of joints are known to lead often to fungoid (tubercular) synovitis and general tuberculosis, occasionally in individuals with good family history. Simple injuries of the eyeball (the anterior chamber of which, as well as the joints, is lined by serous membranes), under conditions as above stated, have also been known to lead to tuberculosis, as recorded by Wolfe (*Brit. Med. Jour.*, March, 1882) and Gradenigo (*Ann. d' Oculistique*, 1870).*

* Primary tuberculosis of the uveal tract was described lately by Eparon (*Arch. d'Ophthalmol.*, November-December, 1883). He obtained his material for investigation from the clinic of Landolt. His observation was confined to those cases in which the uveal tract was primarily and exclusively the seat of a tuberculous infiltration, usually of slow progress. In one case the tuberculous infiltration was confined to the anterior part of the uveal tract, and at first so deep in the tissues as to be inaccessible to direct examination. It developed rapidly, and within a month had caused such grave alterations in the eye as to necessitate its enucleation. There was, however, no tuberculous point of infiltration in any other part of the body, and the patient was cured by the enucleation of the eye.

Dr. M. Litten,† of Berlin, was the first to publish some accounts which demonstrate that miliary tuberculosis may be caused directly and primarily by pleurisy and inflammation of other serous membranes in persons with no phthisical history, and without any cheesy masses being formed in any part of the body. In his (Litten's) experience this was particularly the case when there was a rapid reabsorption of the exudates in case of chronic pleurisy, or if repeated removal of the fluid of a hydrothorax or ascites by tapping had been performed. He records several well-studied cases of that kind, accompanied by autopsy-records. Litten's observations at no time, however, received the attention which they deserved.

Not only clinically but also pathologically this part of the tuberculosis question is rather neglected. In text-books of pathology the occurrence of primary tubercle in adhesive bands is incidentally mentioned, but no special consideration is devoted to its etiology and manifestations.

Upon the autopsy-table I have repeatedly met with subjects with exquisite primary tubercular peritonitis, pleurisy, or pericarditis, which, upon inquiry into the history of the cases, failed to reveal any phthisical or scrofulous history. The products of these inflammations were often plastic in character, not unlike those of fungoid synovitis. The appearances sometimes present themselves particularly strikingly in the peritoneum; all the viscera may be glued together by plastic material into a solid mass. The omentum is usually retracted and matted together into a solid cord or mass, which, lying parallel with the transverse colon, reaches across the abdominal cavity, and may have a thickness of from two to four inches; the mesenteric and other lymphatic glands are usually normal, but sometimes in advanced cases may be much enlarged and more or less cheesy. The entire absence of any cheesy focus in the body is, however, often a conspicuous feature in these cases.

Some pathologists deny the tubercular nature of these formations and of the flat nodular masses which cover the serous

† M. Litten, Sammlung Klin. Vorträge, No. 119: Ueber acute Miliartuberculose, 1877. For further references, see Wiener Med. Presse, No. 36, 1882; Charité Annalen, vol. vii., Berlin; Krankheiten der Respirations-Organen, in Virchow's Handb. der Spec. Path. und Ther., vol. i.; Virchow, Geschwülste, vol. ii. p. 725, etc.; also, Formad, Transactions of the Philadelphia County Medical Society, and of the Pathological Society, for 1882-83.

surfaces in these cases. It is true that fibroid changes predominate in these formations; but numerous tubercle nodules, with all the necessary attributes, epithelioid and giant cells, and necrotic changes, were plainly seen in all cases which I had occasion to examine. Secondary miliary tubercles of quite recent date are also found thickly strewn locally in these parts, and may or may not be seen in the lungs and other organs. As a rule, there is more or less ascites in these cases. My colleague, Dr. E. O. Shakespeare, has recorded similar cases, and Dr. Morris Longstreth tells me also that he has seen and studied such cases. Dr. Mitchell Prudden describes (*New York Medical Record*, June 16, 1883) an allied case.

In chronic adhesive pleurisy there occur similar primary tubercular formations in the organized plastic exudate, which in some cases give rise to secondary (miliary) tuberculosis of other organs. The lungs may be perfectly normal in all parts, and show only peripherally, just below or bordering the pleura, some indurations of gray color made up of recent tubercle tissue. These young tubercle infiltrations may in some cases be seen penetrating into the substance of the lung, as in a pleuro- or dissecting-pneumonia, directly from the old tubercular masses of the adjacent pleural membrane.

I have also examined several cases of plastic adhesive pericarditis, and found the plastic vegetations in this lesion to contain tubercles: two of these had coincident pleuritic lesions.

Cases which came under my observation during the last eighteen months—*i.e.*, since the opening of the bacillary campaign—were, of course, carefully examined for bacilli, and the results may be summarized as follows: bacilli were found in most of the lesions, if the tubercular disease of serous membranes was accompanied by cavities and cheesy masses in the lung, or by tubercular ulceration of the intestines, and if cheesy changes in general were prominent; but no bacilli could be discovered, even after repeated and careful search, in any of the lesions of four cases of primary peritoneal and pleuritic tuberculosis examined. In none of these latter four cases were there any conspicuous cheesy changes in any organ, and no cavities or marked hepatizations in the lung, and no intestinal ulcers, although in two

there was slight pulmonary miliary tuberculosis. These cases will be recorded in detail in a future publication.

I have also seen several cases of primary tubercular pleurisy and pericarditis, and a few of primary tubercular peritonitis, in the pathological institutes of Virchow in Berlin and of Von Recklinghausen in Strasburg. I questioned these foremost men of pathology concerning the etiology of these lesions. They, as well as Rindfleisch, of Würzburg, told me personally their opinion, stating their firm belief that these lesions often directly originated from simple chronic inflammatory changes, without the agency of any cheesy focus or any specific agencies whatsoever.

Birch-Hirschfeld also states, in his book on pathological anatomy (page 183), that "nearly every exudative pericarditis and pleurisy leads to a local tuberculosis, if it takes a chronic course."

How often primary tubercular lesions of serous membranes occur in non-scrofulous persons, and whether this is the only form of tuberculosis in this class of persons, is, of course, a matter of speculation, until thorough statistics and careful studies are made in this direction. Nevertheless, it is a demonstrated fact, as I will show farther on, that primary tuberculosis can be produced in the peritoneum of animals, such as the dog, which are proved not to have any scrofulous tendency. I have seen this myself, and have seen O. C. Robinson in my laboratory succeed in this experiment by the introduction of simple irritants into the peritoneal cavity. Koch also never succeeded, even with the bacillus, in producing tuberculosis in the dog, except when using the peritoneal cavity or the anterior chamber of the eye (which is also a serous sac) as a point for inoculation.

Here is room for hypothesis. I would prefer to believe that tuberculosis could occur only in scrofulous persons, as this would better agree with the *scrofulous anatomy*. It is, however, possible that a scrofulous anatomy of the tissues may be artificially established by the blocking up of the lymph-spaces of the serous membranes by fibrin and molecular *débris* suspended in the serum which is being reabsorbed. This would then be a mechanical process, and not one of infection. If an inflammation occur in serous membranes, resolution becomes difficult through the peculiarity of the exudate. This is

fibrinous mainly, and, forming extensive, usually permanent organized deposits, it impairs the function of serous surfaces quite materially: the reabsorption of new exudates is probably sometimes entirely impossible. Thus conditions may possibly be created in serous membranes, not unlike those of scrofulous tissues, and simple irritants, perhaps the fibrin, may induce in them a similar reaction.

IV.—QUESTION OF CONTAGIOUSNESS.—CLINICAL ASPECTS.

The idea of the contagiousness of tuberculosis is not new, and, like other unfounded views in medicine, it has oscillated, as all fashions will, from one extreme to another for many generations. At present it is entertained by a number of scientists and by a part of the profession. This view has called forth, from time to time, a number of researches whose results were either pro or contra. I shall refer to these subsequently.

Of late it appears that the belief in the contagiousness of tuberculosis has won considerable ground, not so much on account of accurate observation as on account of Koch's discovery of the bacillus tuberculosis.

Another element which seems to have had an influence in this direction is the fact that certain experimenters, formerly believing, from their own experiments, that tuberculosis was non-contagious, were led, later on, to change their opinions on account of the results of subsequent experiments. These later experiments will, however, be shown not to be conclusive.

Before discussing the merits of the bacillus question, I should like first to consider the question of contagiousness from clinical grounds; and should it be proved that tuberculosis is not contagious, then the necessity for a contagium surely falls to the ground.

According to the observations of the most prominent clinicians who have paid special attention to this matter, there is not on record a single authenticated case of tuberculosis as a result of contagium. Among scores of experienced men who deny thus the contagiousness of tuberculosis it is sufficient to mention the names of Virchow, Von Recklinghausen, Stricker, in Germany; Gull, William Watson, Paget, Humphrey, Richardson, in England; Bennet, in France; and Hiram Corson

and Traill Green in our own midst,—all men of close observation, with ripe experiences extending over from thirty to fifty years.

The statistics of the large Brompton Hospital for consumptives, for thirty-six years, with regard to the resident officials, compiled by Dr. F. Williams (quoted from the *Lancet*, 1883), show that of four resident medical officers, one of whom had served twenty-five years, none had any lung-disease; of six matrons, none were consumptive; of one hundred and fifty resident clinical assistants, eight became consumptive and five died, but in only one was the disease developed during residence at the hospital. Since 1867, of one hundred and one nurses, only one died from phthisis, and that after leaving the hospital. Before 1867, six died, three of these of phthisis, but only one became so whilst resident, and she had a consumptive sister. She died thirteen years after first joining the hospital, but was not there the whole time. Of thirty-two gallery-maids since 1867, none developed phthisis while at the hospital. Of twenty house-porters, five died, but none of consumption. Non-residents:—Of nine secretaries, three were threatened with lung-disease, but recovered. Of twenty-two dispensers, seven died, three of phthisis, one while at the hospital. Of four chaplains, three died, none of phthisis. Of twenty-nine physicians and assistant physicians, eight died, none of phthisis. At the Chest Hospital, Victoria Park, there have been five resident medical officers during about the last fifteen years; all are alive and well. Two matrons, neither consumptive. There were two clinical assistants appointed every three months; none known to have developed the disease at the hospital. One nurse out of fifty or sixty in the last few years became consumptive while at the hospital, and she died after a year's illness.

An ingenious plan to decide the question of the communicability of phthisis was instituted by the British Medical Association by establishing the Collective Investigation Committee. This committee sent out questions relating to this subject to all the members of the Society. Of ten hundred and twenty-eight replies received, six hundred and seventy-three negatived the idea of a contagium, while two hundred and sixty-one replies favored it. According to these statistics, there is

a manifest majority in favor of the non-contagiousness of phthisis; yet such a plan is unsatisfactory, as the answers may be of unequal value, since their worth must be estimated in proportion to the experience and authority of the sender.

Not without interest is the observation of Prof. Corradi, of Pavia, who noted that out of one hundred and thirty-three families in which he had cases of consumptives, in only twenty-five of the families were there more than one member of the family ill of that affection.

There is no proof whatever that tuberculosis is conveyed from person to person by contagion. Seeming exceptions to this assertion can almost always be accounted for in some other way.

The assertion that the wife may contract the disease from the husband, I have pointed out, in a former paper, to be untenable; and I have also shown that a predisposition to scrofulosis may be acquired from the unwholesome mode of life led, of necessity, by such individuals.

Besides, it is established statistically that nearly one-third of all deaths occurring in middle life are due to phthisis. In view of the frequency with which this malady occurs, intermarriage between scrofulous individuals may be almost as common as between non-scrofulous ones.

The view taken that children become scrofulous by contagion from phthisical parents may be met by the fact that instances have occurred where a number of young children of phthisical parents were early removed from their homes and distributed among healthy families, and yet all, sooner or later, became phthisical.

Healthy persons have even been fed on bovine tuberculous material (which is considered identical with human tuberculous material) and have thriven on it, as is proved by the interesting feeding-experiments made upon man and recorded by Schottelius (*Virchow's Archiv*, No. 91, 1883). The circumstances which led to this experiment were as follows. In Würzburg the sale of meat affected by pearl-disease, or bovine tuberculosis, is permitted, but, as some opposition to its sale once arose, a community of country-people agreed to use exclusively tuberculous meat, on account of its cheapness and in order to prove that it was harmless. From October, 1867, to November, 1868, forty-nine tuberculous beeves, with well-pronounced lesions, were

consumed by these people while they were under the supervision of the district physicians. In many instances the meat was even eaten raw, in consequence of habit. Ever since then, those people have continued the use of tuberculous meat, and thus far no bad results have been noticed: in fact, the record says that the people referred to are unusually healthy.

I wish to quote, however, some of the strongest affirmative evidence that exists in favor of the contagiousness of phthisis, in order to show upon what meagre clinical support this view is based.

The following case is related by Dr. C. Spriggs (one of the replies received by the English Collective Investigation Committee).

Miss R., aged 48, a dress-maker, living in rather a lonely cottage, had three apprentices, young girls of from 17 to 19 years, not related, from three adjoining villages, who took turns to remain in the house and sleep with her, each one week at a time. During their apprenticeship Miss R. was taken with phthisis, of which she died. In less than two years afterwards all these apprentices died of phthisis, although it is said that in the family history of each no trace of phthisis existed; and the parents, brothers, and sisters of two of them are alive and well at the present time.

Another interesting case is related by Mr. G. F. Black (English Collective Investigation Committee), in which a perfectly healthy child, with a family history free from all trace of tubercle, is reported as becoming infected by a phthisical nurse and having died with profuse hæmoptysis, after the disease had run a rapid course.

Lindemann (*Berlin. Klin. Woch.*, July 25, 1883) related two cases of tuberculosis said to have followed the rite of infantile circumcision. The operator was himself subject to tuberculosis, and both children became ill, and one of them died of tuberculosis.

Another instance is thus given (Dreschfeld, *Brit. Med. Jour.*, 1883): In a small town in Germany, where in the course of nine years only five children had died of acute tubercular meningitis, there happened in the course of nine months eleven deaths from that disease in infants all under six months. All these children were assisted into the world by a midwife who subsequently died of phthisis, and who had been in the habit, when attending a confinement, of breathing into the newborn child's lungs with the view of expanding them.

Lindemann (*Verhand. Innere Medizin, Zweiter Congress, Wiesbaden, 1883*) quotes the following:

A soldier at Strasburg was admitted into the hospital for rheumatism, and his bed was between that of two tuberculous patients. A

few months after his discharge from the hospital he began to cough. He returned to his family and was pronounced phthisical by the physician. Gradually the mother, brother, and father were affected by the disease. The father was attended by a neighbor, who was attacked and subsequently died, followed also by her husband.

Dr. Bela Cogshall, of Flint, Michigan, in a paper read before the American Public Health Association, 1882, quotes the following case after Dr. H. Weber:

A young man, with a well-established phthisical history, married four times, and lost all four wives of consumption. His first wife died after her third confinement; the second wife after a year of married life; the third wife after her second pregnancy; and the fourth wife after her first confinement. All four women are said to have come from healthy antecedents, and to have been "apparently" and "exceptionally" healthy prior to the time of marriage. Finally the much-married man died himself.

There is hardly any comment necessary. By the side of the arguments and facts advanced in this paper such and similar evidence is entirely unsatisfactory, on account of the complete absence of direct proof. On account of the isolated character of the cases and the frequency of occurrence of phthisis, there is just as much reason for inferring a coincidence as a contagium. Furthermore, there is no proof that a family history of scrofula or phthisis or some other causes had been fully eliminated in the cases referred to.*

On the other hand, daily observation and statistics show that there are thousands of instances which disprove the hypothesis of the contagiousness of phthisis. In multitudes of married couples where either the wives or the husbands died of phthisis, the surviving parties were known to have remained unaffected by the disease.

(To be concluded in next issue.)

* Since the reading and discussion of this paper, Dr. William H. Webb, of this city, has kindly sent me his monograph entitled "Is Phthisis Pulmonalis Contagious?" Philadelphia, 1878. It presents an admirable and full résumé of that part of the literature in which the so-called communicability of phthisis is favored. Dr. Webb ably advocates the view that phthisis is contagious. The most interesting passage to me in Dr. Webb's paper is a letter of Professor Alfred Stillé, who, from his clinical observation, extending over nearly fifty years, relates the following:

"I have never seen more than one case in which it appeared to me that the disease was directly communicated. This was a mother, between fifty and sixty, whose husband many years before had died of consumption. She was herself in excellent, tough health up to the date of her daughter's last illness, which was with chronic phthisis with cavities. A day before her death the daughter's breath was very offensive, and the mother, who was lifting her to change the pillows, inhaled it. She spoke to me of the foul taste and acrid

REPORT ON THE PROGRESS OF OTOTOLOGY.

BY CHARLES H. BURNETT, M.D.

PERFORATION IN THE MEMBRANA FLACCIDA, OR SHRAPNELL'S MEMBRANE.

THAT portion of the membrana tympani bounded below by the short process of the malleus and the folds of the drum-membrane, and above by the segment of Rivinus, at the inner and upper edge of that part of the tympanic bone forming the inner end of the upper wall of the external auditory canal, is known as the membrana flaccida, or the membrane of Shrapnell. It is composed of two layers only, an outer, or cutaneous layer, and an inner, or mucous layer; a fibrous layer like the middle layer of the membrana tympani below the folds is wanting in the flaccid portion, and hence one of its names. Its other name, Shrapnell's membrane, is derived from an English investigator, Henry Jones Shrapnell, who first minutely described it.

When a perforation is found in this part of the drum-head, it may be regarded as an indication that purulent disease has invaded the upper part of the tympanic cavity, in the neighborhood of the tegmen tympani and the joints of the ossicles of hearing, especially the great joint between the malleus and incus.

If this perforation be directly over the short process, it may be concluded that the pouch of Prussak has been opened; if anterior to this point, that the anterior portion of the drum-cavity has been especially involved; and if posterior to the short process of the malleus, that the region near the body of the incus, the antrum mastoideum, and even the mastoid cells themselves, may be implicated in the purulent process. These cases are nearly always attended with deafness, and, if the process in the tympanic cavity be still active, by a more or less copious discharge of an especially obstinate recurrence and fetid odor.

They present, therefore, even a grave consideration, since they indicate a purulent disease near the tegmen tympani,

sensation in her throat produced by the inhalation. Within a few weeks she began to cough, fell rapidly into consumption, and died after several months' illness. This is the only case of my own that appears to bear upon the affirmation of the question. On the other hand, if pulmonary phthisis were often conveyed by contagion, the cases ought to be of daily occurrence, since the disease is the most frequent of all mortal diseases."

and, as the latter is but a thin lamella of bone between the tympanic cavity and the brain, they lead quickly to the irresistible inference that the patient's life is in danger from an extension of inflammation to the brain, or from a brain-abscess.

There are often natural dehiscences in the tegmen tympani; and in such cases the mucous membrane of the drum-cavity and the membranes of the brain are in contact. Important as this aural affection is, very little about it is found in the text-books or in the periodical literature of otology, except that which has appeared within the last ten years in this country.*

This apparently has incited at least two observers† in Germany to report their observations on perforation of the membrana flaccida, and to communicate their ideas at the same time upon the pathology and treatment of this most important and not very rare disease.

One of the chief characteristics of a perforation in this part of the membrane is that air cannot be forced through it by any form of inflation. Morpurgo, in his article, tries to prove that air will pass through a perforation in the posterior part of this membrane when the tympanic cavity is inflated. But he apparently forgets that his experiment was performed on a healthy membrana flaccida artificially perforated, and not upon one already perforated by disease. In the latter case, it must still be maintained that the antecedent disease in the mucous membrane would so greatly swell the latter as to preclude the occurrence of a perforation-whistle, through the pathological perforation, by any form of inflation of the drum-cavity.

Again, this author maintains that the removal by irrigation of fetid, cheesy masses through a perforation in the membrana flaccida is a proof that the masses have come from the mastoid region. This cannot be accepted as a conclusive argument, because great masses may be removed from the diseased dome of the tympanic cavity underneath the tegmen tympani, as I have seen in two cases, without involvement of the mastoid cells.

In these cases the differential diagnosis between a morbid process limited to the upper part of the tympanic cavity, and a general one throughout the entire cavity, is aided by the appearance of the drum-membrane.

If in a case of chronic, copious otorrhœa, where a perforation in the membrana flaccida is found, the membrana tympani *in toto* is found to be swollen and red, and the malleus more or less obliterated from view, it may be concluded with considerable certainty that the inflammatory process is general throughout the cavity of the tympanum. In some instances the drum-membrane below the folds, *i.e.*, the drum-membrane proper, bulges as a whole, or at some point, and pressure upon it causes pus to ooze from the perforation in the membrana flaccida. The latter result is proof positive that matter has passed below the perforation, and has sought the lower parts of the tympanic cavity, or, as I believe, may have formed a pouch between the layers of the membrana tympani. If, on the other hand, the inflammatory changes are found only in the region of the perforated membrana flaccida, the rest of the membrana tympani remaining unaltered, that is, not greatly sunken, and with the manubrium of the malleus very prominent, and if no communication between the perforation and the tympanic cavity can be shown by inflation of air, it may be concluded that the process is localized very near the perforation in the upper part of the tympanic cavity.

If, however, the membrana tympani be retracted and possessed of limited mobility, and if there be no perforation-whistle, it may be fairly assumed that a wide-spread process has been present in the drum, but that it has run its course, leaving behind it more or less important changes, and is at last limited to the upper part of the drum-cavity.

In Hessler's article, based on an observation and report of ten cases, great stress is laid on the frequent occurrence of this form of ear-disease in children, and he reports two cases,—one in a child 4 years old, the other in a child of 6½ years,—the youngest cases yet reported. He believes that most cases of perforation in the membrana flaccida date from the earliest childhood. This is not an invariable rule, as I have now under observation a case of this form of ear-disease in a man 25 years old,

† Beitrag zur Pathologie und Therapie der Perforationen der Shrapnel'schen Membran, E. Morpurgo, of Trieste, Archiv f. Ohrenheilkunde, vol. xix, p. 264, 15th March, 1883, and a paper with the same title, by Hessler, Ibid., Bd. xx, p. 121, 8th August, 1883.

whose ear I examined ten years ago for another purpose, and at that time there was no perforation in the *membrana flaccida*, nor any symptoms of purulent disease in the drum-cavity. Hessler regards this form of aural disease as not uncommon, and gives as his experience that it is found in one per cent. of all cases of ear-disease treated. If this be a fact, it is strange that so few reports of cases are found in otological literature. Twelve years ago, Prof. Politzer, of Vienna, informed your reporter that he had seen only a few cases of this form of perforation of the drum-membrane. In his recently-published work on the ear he states that it is of comparatively rare occurrence, but that it does occur more frequently than was once supposed.

Hessler found that a communication existed between the Eustachian tube and the purulent nidus in the tympanic cavity in two cases, as was shown by the whistling of air through the perforation when air was blown into the drum-cavity through the Eustachian tube. Deafness is usually a prominent symptom of this form of ear-disease, but not always.

Treatment.—The first consideration in the treatment of this disease is that it cannot be intrusted to the patient, as nothing he can do through the external ear can reach the diseased spot behind the perforation, the latter being too small to admit drops instilled into the external canal. Furthermore, the diseased cavity behind the perforation is packed with purulent *débris*, which in every instance must be removed before drops or applications of any kind can be put into the cavity so as to medicate the diseased mucous surfaces.

At the head of the list of remedies in this malady stands boric acid,—most efficient in acute forms, but very valuable in the chronic conditions. The chief consideration in the use of any drug is the mode of its conveyance to the diseased cavity. The best method is undoubtedly by means of the tympanal syringe. Morpurgo holds that the best fluid for injecting is a saturated solution of boric acid. In those cases in which the odor is very bad, he resorts to a solution of carbolic acid. The long, slender nozzle of the syringe, filled with the solution to be applied, must be conveyed down the canal under good illumination of the parts by the forehead-

mirror, and with the tip of the nozzle inserted into the perforation an injection may be made. This, of course, must be done at first with the gentlest pressure, or vertigo will ensue. Caustics are not to be used as injections. The best results have been obtained by Morpurgo from the use of disinfectant fluids, combined with the use of alcohol and water in equal parts, after the cavity has been cleansed by the disinfectant. The use of the latter alone may effect a cure. Combined with this treatment at the hands of the physician, the application of alcohol and water in equal parts, or even pure alcohol, to the ear, by instillation, may be carried out at home by the patient.

EPILEPSY CAUSED BY A FOREIGN BODY IN THE EAR.

Dr. Küpper,* of Elberfeld, in Germany, relates an interesting case, as follows. Maria B., 18 years old, came under observation in September, 1881. She stated that about six weeks previous she felt intense pain in her right ear, which had come on without any assignable reason, and had lasted several days, until copious suppuration ensued. About three weeks previous to her admission to the hospital, where she made these statements, she experienced a severe toothache after exposure to cold weather, and for the cure of the pain had, at the advice of a female friend, placed a piece of some kind of root in her ear to cure the pain in her tooth. She was, however, unable to extricate this substance from her ear, and had commenced from that time to show epileptic symptoms. Sometimes every day, and even several times in the same day, with intervals again of several days, she would fall with a scream upon the floor, lose her consciousness, and finally come to herself quite exhausted. Her mother stated that when her daughter was in these fits it required several people to hold her.

Examination of the case revealed that the watch was heard only on contact in the affected ear, bone-conduction was normal, and the external soft parts of the ear were neither red nor swollen. The parts in front of the external auditory canal were very sensitive to pressure, and the auditory canal was full of pus.

* Archiv f. Ohrenheilkunde, Bd. xx. p. 167, 12th December, 1883.

Syringing the ear was followed by vomiting and intense vertigo, so that the patient nearly fell from the chair. The auditory canal was occluded by polypi, which were very sensitive to the touch. Upon one occasion Dr. Küpper had an opportunity of observing the girl in one of these epileptic fits, and of satisfying himself of the insensibility of the pupils. The next morning the patient was etherized and the polypi extracted. Copious hemorrhage ensued, and treatment was suspended. That afternoon the patient had a severe fit, and, as the parts about the ear were very sensitive, three leeches were placed in front of the external meatus. A day or two later the clots of blood were removed by syringing, when in the fundus of the canal a black object was seen. Since syringing could not remove this, and as touching it produced great pain, the patient was again put under the influence of an anæsthetic. By means of a small hook this substance was removed, and it proved to be a piece of wood one centimetre long and one-half centimetre thick. After the removal of this foreign body and the polypi, there occurred two more fits, the first a few hours after the last operation, and the other, two days thereafter. The remnants of the polypi were cauterized with nitrate of silver, and the suppuration in the middle ear was treated by means of a solution of nitrate of silver, and by boric acid powder. In four weeks the patient was cured, the otorrhœa ceased, the perforation in the drum-membrane cicatrized, and the hearing ultimately became normal, as was determined by Dr. Küpper in March, 1883.

CEREBRAL IRRITATION FROM A MASS OF EPIDERMIS IMPACTED IN THE AUDITORY CANAL.

Dr. Küpper* reports in the same paper another case of neurotic irritation from aural lesion. It appears from this account that Miss S., 76 years old, was suddenly attacked in September, 1882, with symptoms of cerebral irritation, without any known cause. She suffered from intense headache and vertigo, vomiting, spasms of the facial muscles and in the muscles of the extremities, those of the trunk being but slightly implicated. Her temperature was normal, pulse 76. The patient com-

plained especially of pain in her right ear, which was very sensitive to the least touch. Examination of the various organs of the decrepit woman revealed them to be in a healthy condition, except the right ear, which was entirely stopped up. The hearing in her left ear was nearly normal, but the right ear was absolutely deaf, and bone-conduction failed. It could not be found out how long the right ear had ceased to act normally. An attempt to remove the plug from the auditory canal by syringing produced vertigo, vomiting, and a severe spasm. Instruments could remove only shreds of the obstructing mass, and hence endeavors were instantly made to soften it. In the course of the same day and night there were frequent attacks of vertigo and spasm, and no nourishment could be retained, by reason of the tendency to vomit. The next morning careful syringing failed to remove anything more than small pieces of the obstructing mass. The latter appeared to cling firmly to the wall of the auditory canal at all points.

Gradually some flakes of the epithelial plug were removed by instruments, and the nervous phenomena diminished in intensity. The fits ceased entirely, and the vomiting became so much less as to permit the retention of food, and the vertigo vanished. The next day the entire obstructive mass was removed. The membrana tympani was found pressed inward against the inner wall of the drum-cavity; it was white and opaque, thick and lustreless. The mass removed from the ear was shining, and of a silver-gray color, and resembled in shape a cast of the external auditory canal. Especially well marked was the impression on its inner end of the form of the membrana tympani. The external auditory canal was considerably wider than the left, and the membrana tympani was adherent to the inner wall of the tympanic cavity. The hearing was destroyed. Examination of the plug removed from the auditory canal showed that it was laminated in structure on the outer surfaces, the laminæ being composed of epithelium without trabecular substance. There were no cholesterine crystals found. The central parts of the plug consisted of ordinary cerumen. The patient slowly regained the ability to walk about. No change occurred in the hearing or in the appearance of the drum-membrane.

* Op. cit., p. 169.

THREE CASES OF EMPYEMA, SHOWING THE ADVANTAGE OF INCISION AND DRAINAGE.

BY V. M. REICHARD, M.D.,

Fair Play, Maryland.

THE accompanying cases occurred in the practice of my friend and former preceptor, J. McPherson Scott, M.D., of Hagerstown, Maryland, by whose kind permission I am allowed to report them. The following abstracts are taken from his case-book:

Case I.—L. E., female, white, æt. 6 years, came under observation in May, 1880, suffering with pleurisy with effusion. Had been under the care of another physician, hence knew nothing of the earlier history. Put on quinine, iron, and cod-liver oil, with nourishing diet. In about a week began to have hectic fever, with rigors and sweats. Suspecting an empyema, passed the needle of a hypodermic syringe and drew away pus. Decided bulging of intercostal spaces, but no pointing. Next day passed a good-sized trocar between tenth and eleventh ribs posteriorly, and drew away about a pint of pus, somewhat to the relief of the child. Inserted a drainage-tube, but it became clogged, and had to take it out. The opening closed. In about a week was as bad as ever. After local anæsthesia, made an incision down into the pleural sac and let out about three pints of pus. The opening was kept patulous with a tent. The discharge continued in diminishing quantity for about two months, when it ceased entirely, and the opening was allowed to close. The child began to improve after the free incision, and now is stout and hearty.

Case II.—B. S., male, colored, æt. 20. In June, 1881, seized with pleurisy with effusion. In about a week began to have rigors and sweats. Passed hypodermic needle and drew away pus. Next day aspirated, and nearly a gallon of offensive pus withdrawn. In about ten days the chest had refilled. Aspirated again, but, owing to defective working of the apparatus, did not succeed well; only about a quart withdrawn. Rigors and sweats continued. In a short time the effusion was so great as seriously to impede respiration. The pleural sac was now freely laid open by incision between tenth and eleventh ribs. A large amount of pus came away. A discharge kept up constantly for several months, though in slightly-diminishing quantity. The case then passed from under observation for about six months. When seen again, the opening had closed; the boy was in the last stage of consumption, and died in a few days.

Case III.—J. W., male, white, æt. 35. In 1872 was called to see him. Was suffering with an empyema. Had had a pleurisy, and an empyema necessitatis formed. A surgeon

had made an opening on lower and posterior aspect of thorax, but failed to get any pus; said it would come all right. Found him with greatly-impeded respiration and suffering very much. He declined any further operative interference. Having no aspirator at hand, took a piece of rubber tubing and fitted it to a barrel syringe. Passed the tubing down into the pus-cavity, and in this way drew away several pints of pus, affording great and instant relief. He was soon about again. Urged an operation, which he declined, saying he would "stick to the first apparatus." A discharge, never very profuse, was constantly kept up. When there was trouble in breathing, we resorted to the syringe and tubing. In 1880 he had a hemorrhage into the pus-cavity. Was relieved by passing catheter and washing it out. The washing would relieve the discharge, but not cure it. Tubercles now began to develop in the lungs. In the spring of 1881 had another hemorrhage into the sac. In December, 1881, died of phthisis pulmonalis.

These cases present some points for study. They show that the best chance for recovery is after free incision. Whether the case be one of suppurative pleurisy or one in which a serous effusion has become purulent, the indication is the same,—free incision. The pleural sac is simply a pus-cavity, and must be treated as such. In Case I. improvement began as soon as free drainage was established. The child is now robust, with very little retraction of the chest-wall. In Case II. aspiration was given a fair chance, but failed entirely. It is a fact observed by all who have had much experience with negroes that thoracic diseases are badly borne by them. Under the continued drain, tubercles developed, and he died with acute consumption, although the empyema was almost cured.

Case III. is another against aspiration. Though the pleural sac was often emptied and washed out, drainage was never fairly established, and at last the system succumbed to the purulent secretion,—only, however, after the lapse of nine years. Had an incision been made through the chest-wall, and this pus-cavity been treated as one in any other part of the body, the result might have been different.

It is of the first importance that the incision be made into the lowest part of the sac. In some subjects it is not an easy matter to find the lowest ribs. In such cases a good plan would be to aspirate with the hypodermic syringe. Even if the needle were passed below the diaphragm, no harm would result.

AN INSTRUMENT FOR PLACING SHOT UPON WIRE SUTURES.

BY THOMAS S. K. MORTON, M.D.

HAVING noticed the frequent annoyance, inconvenience, and delay of operators in using the shotted-wire suture from the shot slipping from either their fingers or those of an assistant, and the difficulty of getting the ends of the wire through the perforation, or, after coaxing the wires into it, of finding this perforation incomplete, to obviate these difficulties I have devised the instrument which is shown in the accompanying wood-cuts, and which my father and others have been using of late with much satisfaction.

It consists of a hollow metal cone, one-half inch diameter at base, and one-half inch in height, having at its apex a perforation (sufficiently large to admit two strands of any wire likely to be used) which opens into a chamber the exact size of the shot intended for use. Directly opposite this entering opening is another, slightly conical, communicating with the exterior, the apex being its outer termination. The whole is split into two symmetrical halves, and each mounted obliquely to its axis and vertical to its section on one arm of a pair of crossing forceps.

Instrument and loading-pin.
(One-fourth actual size.)

Actual size.
(Open.)

Then, having a number of shot, which must be bored and punched to secure uniformity, strung on the pin provided for the purpose (see cut), the arms of the forceps are opened, a shot is placed in one of the separated halves of the shot-cham-

ber, and the forceps allowed to close, thus embracing the shot and pin, which latter is now drawn out and the instrument is ready to be presented to the ends of the wire, which pass along the cone, through the shot, and out behind.

When the arms are again separated, the shot is upon the wires, ready to be run down and compressed; an assistant in the mean time places another shot in the chamber, ready for the next stitch.

Chief among the advantages of this instrument may be mentioned: the shot require no handling, and after loading cannot be dropped or mislaid, and, being bored, must be pervious; also shot with a finer perforation can be used, and thus a small shot be equal in strength to a much larger one as now used: the wires do not require to be twisted and cut, and if the ends presented to the cone are not more than one-half inch apart, they are bound to pass through the shot; the fingers do not obstruct the view, and if a known number of shot be upon the pin at the beginning of the operation, the number of sutures put in can be ascertained by the number missing.

TRANSLATIONS.

A CASE OF GASTRIC FISTULA WITH DIGESTIVE EXPERIMENTS.—Dr. De Cernville reports (*Revue Médicale de la Suisse Romande*, January 15) a case of gastric fistula, and Prof. Herzen communicates in the same article some physiological observations made upon the patient. A vine-dresser, 28 years of age, of intemperate habits, and a confirmed dyspeptic, was found to be suffering from fibrous thickening and contraction of the cardiac orifice of the stomach, with dilatation of the œsophagus. As the stricture appeared impassable, it was decided to perform gastrostomy. The incision was made parallel with the costal cartilages on the left side, and was about five centimetres in length. The muscles and aponeuroses having been cut through, the peritoneum was then incised, and the adjacent wall of the stomach was fastened to the edges of the wound by a circle of sutures of catgut and of metal, passing through the stomach, peritoneum, and integuments, and the wound was covered by a Lister dressing. The patient was nourished by enemata contain-

ing raw meat and pepsin, and did very well after the operation. On the second day, the portion of the stomach comprised between the ligatures was incised without difficulty, and without pain or notable hemorrhage. Into the stomach a tube was inserted, and a quarter of a pint of broth was introduced; in the evening half a pint was given. Subsequently he was fed regularly with milk and broth, and cure was rapid; the sutures were removed on the eighth day, when the adhesion seemed perfect and sufficiently solid. It was found that a tube (such as is used for dogs) could not be used, as part of the gastric juice escaped by the side of the canula and caused excoriations, due to digestive action upon the skin. The best method of closing the wound was a tampon of wadding, covered by a concave plate, and held in position by a girdle. All efforts at dilatation of the cardiac orifice failed.

In the course of his investigations, Prof. Herzen discovered some interesting facts. Each morning, after fasting for twelve to fourteen hours, it was found that the stomach contained from two hundred to three hundred centimetres of an acid liquid, evidently stained with bile. This had a feeble digestive power. On two occasions experiments showed that it contained no pepsin. After this fluid was removed from the stomach, another liquid took its place, a liquid absolutely colorless, limpid, extremely thick, ropy, something like the white of an egg. In quantity it was less than the preceding, but its digestive action upon albuminoids was much more active, although still not so much as the normal gastric juice poured out during digestion. Remnants of food were detected in the stomach after a slight repast for at least six hours, but they completely disappeared in twelve hours. It was noticed that hunger began some time before the stomach was entirely empty of food. It was remarked with regard to the first (or bile-stained) fluid found in the stomach, that it disappeared into the duodenum very shortly after applying any irritant to the fistule, but that if the bandage were allowed to remain undisturbed the fluid would remain indefinitely. The fact that the gastric juice in the morning is deficient in pepsin should lead to some correction of diet: for instance, hard-boiled eggs eaten by themselves were found to give indigestion, but by using with them

a peptogenic fluid, such as a solution of dextrine or a cup of broth, the discomfort was avoided.

THE MODE OF PRODUCTION OF THE TENDON REFLEX.—Jendrassik has made a number of experimental studies of the various conditions which are necessary for the presence or absence of tendon reflexes, particularly for the patellar reflex. The following conclusions express the most important of his results:

1st. The "knee phenomenon" is a true reflex action, brought about by the mechanical irritation of the nerves situated in the patellar tendon. It is not necessary that the stimulus should be applied at the junction of muscle and tendon: stimulation of the part of the tendon lying farthest from the muscle is equally efficacious.

2d. For the production of the reflex muscular contraction it is necessary that the muscle be passively extended: to a certain degree the contraction of the muscle is proportional to the stretching to which it is subjected.

3d. Voluntary innervation of the crural nerve diminishes the patellar reflex, or may prevent its appearance altogether. Contraction of the muscles innervated by the sciatic nerve, however, instead of preventing rather favors the development of the patellar reflex.

4th. The path of the reflexes lies in the spinal cord only in the gray matter. Lesion of the white columns cannot directly be a cause of the absence of the reflex.

5th. Physiological increase of the tendon reflex is also produced by contraction of the other body-muscles: thus, simultaneous lifting of weights, or strong stretching of muscles, increases the reflex.

6th. In the majority of cases pathological increase of the patellar reflex may be regarded as the result of an interruption of the conduction of inhibitory impulses from the brain to the spinal cord.

7th. The author does not regard the "foot phenomenon" as a reflex, but rather as a tonic contraction, directly produced through the mechanical stimulus given in the sudden stretching of the soleus: the irritability of the muscle must therefore be increased.

In five instances severe stretching of the crural nerve in rabbits left the patellar reflex unaltered.—*Centralb. für die Med. Wissen.*, No. 49, 1883. S.

EDITORIAL.

NEW YORK STATE MEDICAL
SOCIETIES.

THE County Societies of New York State have been requested to send delegates to form a New State Medical Society in New York in November next. The establishment of a second New York State Medical Society seems an actual necessity, from the persistent spirit of opposition to the American Medical Association shown by the leaders of the dominant faction in the old State society, which deliberately forfeited its right to representation in the National Association. From remarks made during the discussion of the subject, it would almost seem that the object of the great revolt, after all, was not so much to get rid of the old Code of Ethics as it was to "shake off the shackles" of the national organization, as it was elegantly and forcibly expressed by a prominent ear specialist of New York, who declared his belief that other State Medical Societies would soon be found to follow the example. We are at a loss to understand why the yoke of the American Medical Association should suddenly have become so galling. As an "annual picnic" and a "junketing association," a representative body without corporate existence, and deriving its authority solely from the delegates in attendance at the meetings once a year, it certainly could not greatly interfere with New York physicians. Is their course to be explained on the theory that they had decided upon doing what they knew could not be approved by their medical brethren throughout the country, and they therefore attempted to escape censure by breaking

their part of the contract made upon entering the national organization, and dishonoring their pledges to support its laws?

PHYSICIANS' ACCOUNTS.

PHYSICIANS generally are not credited with being very good business men, and in case of death their heirs often suffer loss on account of the difficulty experienced by the executors in deciphering their books. It sometimes happens that the physician is so busy with his engagements that he postpones his clerical work and neglects entering his charges for weeks at a time, keeping his memoranda upon loose slips of paper which are easily lost or mislaid. No better illustration could be given of the truth that delays are dangerous. With regard to the manner in which his books should be kept in order to make them books of original entry which may be introduced as evidence in court to defend a claim, an important decision has just been rendered. Judge Ashman, of the Orphans' Court (December term), in giving an opinion upon a medical account, declared that "if the books are so kept as to cover a daily entry of each visit, with the name of each patient, a list of the medicines furnished, and the price which custom has fixed for the particular service, such a record will comprise all the incidents of certainty of time, person, labor, and value, and each entry will be complete in itself." He also declared that the ordinary diary or visiting list, in which the records are kept with signs or hieroglyphics, instead of amounts, "could serve at best only as memoranda from which to make more formal charges;" such accounts could not serve as original entries in order to prove services rendered, in a court of law.

It is also well to remind physicians that, in making out accounts, a visit *per se* cannot be considered as a proper ground for a charge: the account should be made

out for services rendered at the request of the patient or of the person responsible for the account.

RESULTS OF RESECTION OF THE KNEE-JOINT AS AFFECTED BY AFTER-TREATMENT.

IN scarcely any department of surgery are the advantages of modern methods more evident than in the operations upon joints. Dr. J. Mensing has recently published* an analysis of ninety-two cases of resection of the knee-joint performed between the years 1857 and 1883 in the clinic at Kiel, dividing the cases, for the sake of comparison, into three classes. In the first class fall all the cases operated on before the introduction of Lister's method of dressing and Esmarch's bandage; in the second group are the cases treated by these methods; and in the third class are the cases in which Neuber's permanent dressing was used in the after-treatment.

Regarding the cases, first, as a whole, there were eighty total and three partial resections for chronic fungoid inflammation of the knee-joint, and nine cases of wedge-shaped excisions to overcome deformity resulting from this disease. In fifty-one cases the joint-affection originated in the synovia, in sixteen cases in the bone, and extended to the joint; in the remainder of the cases no note is made in reference to this point.

Forty-eight of the operations (52.1 per cent.) resulted in cure; of these the operation was performed for primary synovial gonitis in thirty-three, for primary osteal gonitis in six, and for ankylosis in seven. The subsequent histories of thirty-two of these cases were followed up, with the result that in most of the cases the leg remained extended and useful, while in three cases moderately marked flexion occurred; in two cases the disease returned,

in one to be treated by a second successful resection, and in the other by amputation.

Of thirty-four cases, twenty left the hospital while a fistula remained, and secondary amputation had to be performed in fourteen. Of those leaving before the cure of the fistula, it was subsequently learned that in ten perfect healing resulted, and in two cases death, in one case from amputation of the thigh, and in the other from secondary resection, while still another case at the time of the report was suffering from albuminuria. Of the fourteen instances in which secondary amputation was performed in the hospital, twelve were completely successful, one died from septicæmia, and one left the hospital with a fistula and died from phthisis six months later.

Of the ten cases in which death resulted directly from the resection, five were from pyæmia, one from Bright's disease, one from miliary tubercle, two from exhaustion, and one (a bleeder) from uncontrollable hemorrhage.

The comparison of the results obtained in the three different periods before alluded to is very instructive:

Period.	Number of cases.	Cured.	Not Cured.	Died.
I.....	21	5 = 23.8%	9 = 42.9%	7 = 33.3%
II.....	23	7 = 30.4%	14 = 60.9%	2 = 8.7%
III.....	48	36 = 75. %	11 = 23. %	1 = 2. %

The solitary case of death in the third period was that of a bleeder, who died from hemorrhage six days after the resection and two days after the secondary amputation of the thigh.

Another very great advantage of the permanent dressing is that it reduces the duration of treatment from one hundred and twenty-nine days, the average in the first two periods, to eighty-nine days.

THE ETIOLOGY OF PHTHISIS.—The fact of the question as to the pathological relations of phthisis and bacilli occupying so

* Centralb. für Chirurgie, December 8, 1883.

great a share of scientific attention at the present time must be our excuse for devoting so much space to this subject in the present issue. The next number will show the usual variety of topics.

NOTES FROM SPECIAL CORRESPONDENTS.

SIAM.

MR. EDITOR,—The following notes of native practice of medicine are thought to be of sufficient interest to warrant publication.

A NOVEL EMETIC.

Not very long ago, a young Siamese lady, wishing to put an end to her existence, swallowed a large quantity of opium. Mustard, warm water, and various emetics were tried, without avail. Finally the old Siamese doctor procured an eel, clipped off the end of his tail to make him squirm in a lively manner, then poked the slimy fellow, tail first, down the dusky maiden's oesophagus. Emesis was produced immediately, and the rash one's life was saved by an eel.

A NEW REMEDY FOR SNAKE-BITE.

Several months ago, a Siamese man was bitten on the toe by a small snake which the natives regard as a deadly variety. A common barnyard fowl was quickly found, and the injured toe was inserted in the cloaca without delay. The poison was rapidly absorbed by this intestinal pouch, and the hen died, apparently from the effects of the same, in a few minutes, while the man did not suffer at all from the effects of the bite. This seems to me to be worthy of further experiment.

A NEW REMEDY FOR ASTHMA.

One sultry day during the rainy season, an asthmatic old man came panting up my steps, breathing with the greatest difficulty. He rested a few moments, and then asked, in the gravest manner possible, if I had any tigress's milk. He seemed much disappointed when answered in the negative. His Siamese doctor had assured him that this article would prove an infallible remedy in his case. He refused other medicine, and went sorrowfully away.

SIAMESE REMEDY FOR RINGWORM.

I have just noticed Tong-Pang-Chang, an Indian remedy for ringworm, advertised in one of the London papers. Tong-Pang-Chang is a Siamese name, meaning a thousand catties of gold. The preparation advertised is a tincture made from the roots of the

Rhinacanthus communis. This plant grows here like a weed. By taking the fresh roots and bruising them well, and allowing them to remain in alcohol forty-eight hours and filtering, we obtain a beautiful claret-colored tincture. This remedy I have used in hundreds of cases, always with the best results.

Medical Missionary.

PETCHABURI, SIAM, December 6, 1883.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, JANUARY 24, 1884.

The Vice-President, Dr. E. O. SHAKESPEARE, in the chair.

General tuberculosis of serous membranes.
Exhibited by Dr. W. E. HUGHES.

CAROLINE K., white, æt. 17, was admitted to the University Hospital November 3, 1882. There was a history of articular rheumatism in father and mother. The family was free from consumption. She herself had been perfectly well till eight months previous, when she developed symptoms of acute pleurisy. The acute symptoms subsided after a few days, and, with the exception of slight dyspnoea and hacking cough, she soon felt as well as before. Two months afterwards she had pain, swelling, and redness, involving successively all the large joints of the body, lasting ten weeks, and disappearing completely. From the outset of the articular affection her strength and flesh failed steadily, appetite grew poor, and digestion defective. Both dyspnoea and cough increased slightly. Five weeks before admission she began to have occasional sharp pains through the abdomen, and noticed that the abdomen was gradually enlarging. When first examined, she was pale, somewhat emaciated, and had hacking cough with mucous expectoration, slight, constant dyspnoea, very little increased on exertion. The right pleural cavity was filled with fluid up to the third rib; the abdomen much distended with fluid, free to move. The heart was normal in size, but there was a strong mitral systolic murmur. She had an irregular hectic fever. Under treatment the pleural effusion rapidly subsided, but that of the abdomen less rapidly. One month after admission, symptoms of meningitis developed, and examination of the eye-ground showed descending neuritis. A week afterwards, a double pericardial friction-sound developed over the sternum opposite the third intercostal space. She died December 16.

Autopsy, seven hours after death.—Thorax,—right pleural cavity completely obliterated by organized plastic adhesions. In the ad-

hesions numerous gray miliary tubercles were found. Right lung congested, compressed, and contained scattered miliary tubercles. Left lung contained a few miliary tubercles; pleura normal. Heart normal in size. Marked thickening of mitral leaflets, with incompetency. In the pericardium, at upper part of anterior surface of left auricle and over base of aorta, were a few small grayish granulations, apparently tubercular. Peritoneal cavity contained about two quarts of straw-colored serum. Peritoneum everywhere thickly studded with gray miliary tubercles. Old peritoneal adhesions in several parts of abdomen, notably in left lumbar region and around pancreas. These old adhesions were filled with miliary tubercles. Lymphatic glands moderately enlarged, not cheesy. Numerous gray miliary tubercles in membranes of base of brain, especially in Sylvian fissure. No tubercles in any organs except the lungs.

Tubercular ulcers of intestines, with perforation. Exhibited by Dr. W. E. HUGHES.

William T., white, æt. 30, was admitted to the University Hospital April 16, 1883. His mother and a sister died of phthisis. He always took cold easily, and was never strong. Two years ago, after lifting a heavy weight, he had several slight pulmonary hemorrhages. At that time he had no cough. Four months before admission he took a heavy cold. From that time up to his admission he had a dry, hacking cough, with mucous expectoration, some dyspnoea, pleuritic pains on the right side, and a few small hemorrhages. He lost twenty pounds. On admission, there was in the lower part of the right pleural cavity an effusion localized in the posterior half. Over the right lung the respiration was somewhat roughened, with an occasional bronchitic rhonchus. The left lung was normal. Under treatment the effusion subsided, but consolidation commenced at the apex of the right lung. The consolidation went on to breaking down, and the same process commenced at the left apex. He gradually failed, with the usual phthisical history. One month before death uncontrollable diarrhoea developed, with severe colicky pains and intense tenderness throughout the abdomen. He died December 26, of gradually increasing asthenia.

Autopsy, three hours after death.—Great emaciation. The right pleural cavity was completely obliterated by firm old adhesions. In the left there were some adhesions at the apex; no fluid. The right lung had numerous small cavities in the apex. The lower two lobes were riddled with miliary tubercles and small cheesy masses. The left lung was, at the apex, indurated with tubercular and cheesy deposits. In all other parts it was healthy. Bronchial glands were enlarged. The heart weighed four and one-half ounces. The aorta was slightly atheromatous. The

liver weighed two and one-half pounds, and was somewhat nutmeg-like in appearance. The spleen weighed two and two-thirds ounces. The kidneys were normal in size and appearance. The intestines were everywhere adherent to each other and to the abdominal wall, and scattered through the adhesions and over the peritoneum were a few miliary tubercles. The small intestine contained tubercular ulcers strung along its length from the lower part of the duodenum to the ileo-cæcal valve. They were about as numerous in the upper part of the intestine as in the lower. Several of these ulcers had perforated the peritoneal coat; but the contents of the intestines were prevented from exuding into the abdominal cavity by adhesions which had formed around the perforations to the neighboring peritoneal surfaces. There were a few tubercular ulcers in the colon. The mesenteric glands were enormously enlarged.

Phthisis following empyema; amyloid kidneys; cancer of uterus. Exhibited by Dr. W. E. HUGHES.

Amanda F., white, æt. 38, was admitted to the University Hospital for cancer of the uterus. She had been a serving-woman, and had been much exposed to draughts. Her mother died of cancer of the uterus. There was no phthisical family history. One of her children died of tubercular meningitis. While in the hospital she complained of pulmonary symptoms, and physical examination of her lungs showed on the left, posteriorly, flatness down to midway between the spine and the angle of the scapula, with blowing breathing and gurgling râles; anteriorly, tympany, with metallic, cavernous breathing; at the base a small amount of fluid free to move. On the right, hyper-resonance, with exaggerated breathing, and at the apex moist râles. Her general condition was much below par. She had a troublesome loose cough, with free muco-purulent expectoration, and pleuritic pains through both sides of her chest. Five and a half years before, she had taken a severe cold, from which she dated all her trouble. With the cold there had been severe pleuritic pain in the left side, some dyspnoea, and slight muco-purulent expectoration, occasionally streaked with blood. In a month she had lost twenty pounds. Afterwards the acute symptoms disappeared, the pain grew less severe, the cough looser, and the expectoration quite profuse. She slowly lost ground till about a year before, when, after a succession of heavy colds, her condition deteriorated more rapidly. There was more dyspnoea, more cough, and an occasional rise of temperature preceded by chilliness. During this year she had several pulmonary hemorrhages. For a month the frequency of micturition had been much increased, but the urine contained no albumen, though the quantity was increased and the specific gravity

somewhat lowered. The first symptoms of cancer of the uterus had appeared about seven months before. For more than a month after admission she improved; then, a day after a rather profuse pulmonary hemorrhage, she developed a typical uræmic condition. The urine was very scanty and loaded with albumen, but contained neither tube-casts nor blood. The uræmic condition disappeared after two days, and the urine increased to its former quantity, all but a trace of the albumen disappearing. Two weeks after this, for the first time, a few waxy and epithelial casts were found in the urine. From this time on, the quantity of urine passed daily varied from fifty to seventy ounces; its specific gravity ranged between 1008 and 1015, and the quantity of albumen contained steadily increased, till, towards the end, it became as much as one-third of the bulk of the urine. At no time were very many tube-casts present, though they were never absent; they were either waxy or epithelial. She died January 1, 1884, of uræmia, which had gradually developed.

Autopsy, five hours after death.—Much emaciation. The left lung was compressed, atrophied, and firmly bound down in the posterior part of the pleural cavity. The remainder of the cavity contained gas and about eight ounces of sero-pus. The pleura was much thickened, and transformed into a pyogenic membrane. The lung itself was hollowed out into a large cavity, with suppurating walls, by an extensive series of bronchial dilatations, with more or less destruction of lung-tissue. The lung was so torn in its removal that it was impossible to say whether or not there had been a communication between it and the pleural cavity. The right lung was emphysematous, and contained some tubercular and cheesy deposits at the apex. The heart weighed nine ounces; its right cavities contained an unusually-developed ante-mortem clot, closely moulded to the pulmonary valve. The kidneys weighed eleven and a half ounces, and presented very characteristic amyloid change. The body of the uterus was unchanged, but its cervix and the upper part of the vagina were destroyed by cancerous ulceration. There was no infiltration of the lymphatic glands. Other organs normal.

Secondary tuberculosis of the bladder, ureter, kidney, and supra-renal body. Exhibited by Dr. W. E. HUGHES.

Ida G., white, æt. 19, had suffered with the usual symptoms of phthisis for about nine months before she came under observation. Her father and a sister had died of phthisis, and she had always taken cold on the slightest exposure. When first seen, she was standing leaning over the back of a chair, suffering the most agonizing pain in the region of the bladder. Desire to urinate was constant and

irresistible, and the passage of the small quantity of urine gave rise to such suffering that she would shriek and almost faint. Till two weeks previous there had been no trouble with the urine; then the pain began, slight at first, and became gradually more and more severe. She had passed frequently masses of clotted blood, with great suffering. Under anodynes the pain became less, and an examination of the bladder showed it to be much contracted, with roughened walls. Examination also brought on a slight hemorrhage. The urine contained nothing abnormal except blood and pus. Under the continued use of anodynes the pain decreased and finally disappeared. After the cessation of pain, the blood disappeared from the urine, but was replaced about two months afterwards by a small quantity of albumen and a few granular tube-casts. About this time œdema began in the ankles and gradually involved the whole of the lower extremities. The tissues finally became so distended that her legs were utterly useless. The urine never contained more than one-tenth of its bulk of albumen, and the tube-casts were always few in number. She died of asthenia four months after coming under observation.

Autopsy, fourteen hours after death.—Extensive degeneration of lungs. Liver was extremely fatty, being of a uniformly yellow color, with no distinction whatever between its lobules. The bladder was small and firmly contracted, its walls thickened, its inner surface roughened, rugose, papillomatous, its mucous membrane thickly studded with tubercle granulations. The substance of the right kidney contained numerous gray miliary tubercles; its pelvis was dilated and presented the same appearance as the inner surface of the bladder. The corresponding ureter was as thick as an index finger; its walls firm, hard, infiltrated with tubercular deposit; its mucous membrane in the same condition as that of the pelvis of the kidney. The right supra-renal body retained none of its original structure: it was a mass of cheesy tubercles, firmly adherent to the kidney. The left kidney, as well as the other organs, was normal.

DISCUSSION.

Dr. FORMAD had examined these specimens for bacilli. None were found in the first case, although the post-mortem was made within about two hours after death and frozen sections at once cut. The lymph-glands were also examined, as well as the lungs, without detecting any bacilli. In Dr. Hughes's second case the lymph-glands as well as the perivascular spaces were crowded with colonies of bacilli. In the first case was an absolutely primary tuberculosis of the serous membranes, with no bacilli, while in the second ulceration was present with lymph-gland

bacilli, as well as invasion of other tissues. This would indicate that bacilli and general tuberculosis most commonly result from surface-troubles, *i.e.*, the mucous membrane of the lungs, intestines, etc., when affected by tuberculosis. In the case of tuberculosis of the serous membranes there was no history of a strumous diathesis, and no general tuberculosis ensued. From a careful study of ten similar cases Dr. Formad was inclined to think that serous tuberculosis was the only form of the disease to which *non-strumous* individuals were liable.

Dr. SHAKESPEARE said that he had been struck with the fact that the third case, with a family history of carcinoma, apparently developed tuberculosis after empyema, and that at the post-mortem carcinoma of the uterus was found. An antagonism between these two diseases has been long believed in, but of late has been questioned, since a careful scrutiny of statistics has shown them to be more commonly associated than is generally believed. Dr. Shakespeare then called attention to the fact that in most cases a family history was obtained running back for only one generation, yet, there being no statement as to the degree to which the investigations had been carried, statistics drawn from such sources must be unreliable, as Dr. Formad, among others, has called attention to the fact that tuberculosis can and often does skip one generation. There were some points in the history of the case of tuberculosis of the serous membranes which suggested that the primary trouble might have arisen in the joints, which are closely analogous to serous sacs, if they are not actually such.

Dr. HUGHES said that in the case of the patient where he had stated that the family history was good, he had gone back for three generations directly and collaterally.

Dr. MUSSEY asked what was the effect of repeatedappings on the development of tubercle, as some clinical teachers are now advising against such operations in simple pleurisy, advocating in preference other remedies to induce rapid absorption of the effusion.

Dr. J. C. WILSON thought that this question could only be answered by an analysis of a large number of cases specially examined for this purpose.

Dr. SHAKESPEARE, having been informed by Dr. Hughes that the so-called tubercles in the case of carcinoma had not been examined microscopically, suggested the reference of this specimen to the Committee on Morbid Growths, since it might really be only a case of miliary carcinosis, and not tubercle. With reference to the influence of tapping on the development of tubercle, experience showed that it most frequently developed where no tapping had been performed, but where rapid resorption had taken place. Pathological experiment has shown with what ease any in-

nocuous substance, even simple traumatism, will set up tuberculosis of the serous membranes. If, then, a general tuberculosis can result from tubercle of serous membranes,—a point not settled as yet by experimenters,—repeatedappings, with, perhaps, the coincident introduction of deleterious substances, might account for the alleged fact mentioned by Dr. Musser.

Tumor of the anterior mediastinum, with secondary deposits in the heart and lungs.
Presented by Dr. J. C. WILSON.

The specimens were removed from the body of an unmarried woman, aged 60 years, who died in the hospital of Jefferson Medical College January 7, 1884. The patient had been singularly free from sickness until about eighteen months before coming to the hospital, three weeks prior to her death. The earliest symptoms were fixed pains of varying intensity in the sternal region, with attacks of palpitation and dyspnoea. These symptoms increased in severity and were aggravated by exertion. After a time she began to experience difficulty in swallowing. Six weeks before admission to the hospital her feet and legs were for the first time observed to be swollen. The dropsy soon became general. She had no knowledge of her family history.

On admission, she suffered from constant dyspnoea, paroxysmal, often urgent, worse at night; inability to lie down; occasional unproductive cough; a sense of weight and oppression in the chest, and particularly in the precordial region; pain under the sternum, and great discomfort in swallowing. There was a high degree of general anasarca and the evidences of pleural and peritoneal effusion. The surface was cool, the skin bluish. The examination of the chest was rendered difficult by the unusual thickness of the tissues, the patient being not only enormously dropsical, but also very fat, and the breasts being hugely developed. It was nevertheless noted that the impulse of the heart was feebly felt, the apex beating in the sixth interspace and somewhat to the left of its usual position; that a faint systolic blowing murmur was heard at the apex, feebly propagated towards the left; that the heart-sounds at the base were unusually obscure, and that the pulse was feeble, frequent, and irregular. There was flatness with absent respiratory murmur at the base of the chest on both sides, and harsh broncho-vesicular respiration over the upper regions of the chest.

In the upper sternal region the cutaneous venous twigs were conspicuous, without rising, as is sometimes seen, above the level of the skin. They were dilated and tortuous, and symmetrically arranged beyond the sternal borders, at which they abruptly ceased.

The thyroid body was enlarged and formed an egg-like projection in the median line. It

was exceeding hard, but not sensitive or the seat of pain. The patient regarded it with indifference, and said that *the lump* had existed for "many years."

I was unfortunately prevented from being present at the autopsy, and this tumor was not removed.

The boundaries of dulness in the pericardium could not be distinctly made out. It was, however, noted that the distribution of pressure-signs absolutely negated the existence of aneurism of the aortic arch as their cause. The pupils were equal in size and in response to light, the voice was unchanged, the radial pulses equally feeble.

The patient died suddenly in an attack of dyspnoea at 9 P.M. on the 7th of January.

Necropsy.—Body much swollen and oedematous; face and thorax very blue. Both the pleural sacs and the peritoneal cavity contained fluid in large amounts. Strong pleural adhesions on left side. The anterior mediastinum in its upper segment was occupied by a large firm mass, mammillated in structure, extending from the notch of the sternum downwards five inches, and adherent to that bone and the costal cartilages. The width was about three inches, and its depth in an anteroposterior direction about the same. It occupied exactly the position of the thymus gland. Its visceral surface was embossed, but smooth; in its upper portion only adherent to the great vessels. No adhesions existed between the parietal pericardium covering its posterior surface and the visceral layer of the pericardium.

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting was held February 7, 1884, FORDYCE BARKER, M.D., LL.D., President, in the chair.

THE PREVENTION AND TREATMENT OF PUERPERAL FEVER.

(Adjourned discussion of Dr. Thomas's paper on this subject, read before the Academy December 6, 1883.)

According to previous announcement, the discussion was opened by the President, who, on account of difficulty of voice, requested Dr. G. Griswold to read his paper for him. In his opening remarks the President said, "During the five years which I have had the honor to occupy this chair I have never before seen a meeting of this Academy so enthralled by the charm of elocution, the fascination of rhetoric, the glow of conviction, and the air of one who speaks by authority—an air which can never carry weight unless it has been before fairly and justly earned by good work—as on the evening of December 6, when the paper was read on 'The Prevention and Treatment of Puerperal Fever.' Its authoritative tone, its earnestness and sincerity, its coloring of being based on experience and observa-

tion, instead of being unconsciously deduced from preconceived theory, give the paper such a plausible air of scientific truth as must secure its acceptance without question by many minds whose belief rests on authority without examination of the data or analysis of argument." The President thought it a duty to examine novelties of doctrine and practice brought before the Academy and subject them to the tests of advanced science of the day and the accumulated experience of the past. Again, in view of some past controversy, aside from the scientific aims of the Academy, it seemed to him important that the general profession should know that in this hall there could be the strongest antagonism in views relating to science, the keenest encounters in intellectual gladiatorship, carried on with all the courtesy of the duello, without individual hostility or the interruption of personal friendship.

Dr. Barker thought all would agree that the paper read by Dr. Thomas was remarkable for originality, in that some of its pathological doctrines and practice taught were not to be found in any work on obstetrics or taught by any writer of acknowledged repute. He would give, in as concise language as was consistent with clearness, his reasons for believing that the whole tone and coloring of the paper were misleading and dangerous because supersaturated with septic infection. He believed, however, that puerperal septicaemia was one of the most dangerous incidents which might occur to the puerperal woman; and ten years ago he delivered a lecture on this subject, covering thirty-seven pages. Although desirous to correct any errors of opinion which he might have fallen into, and to accept new views suggested by advanced science and tested by clinical observation, yet he had found no reason to make any essential change of the views expressed in that lecture. But the paper which was the subject of discussion took the decided ground that puerperal fever was puerperal septicaemia. The author's view seemed plainly to be that metritis, phlebitis, peritonitis, and cellulitis were never seen in the puerperal woman except from the introduction of septic poison at a lesion in some portion of the genital tract. This pathological view had rapidly gained ground during the past few years as a result of the interest excited by German scientists, whose studies were largely of the micro-organisms in puerperal women in hospitals. Dr. Barker thought that no one had yet maintained that the process of parturition and the puerperal state exempted a patient from causes which may excite local inflammation in the non-pregnant woman, or would deny that parturition and attendant conditions, other than the absorption of septic poison, might be sufficient to excite local inflammation. It was his belief that in private practice, when no epidemic influence was

prevailing, twenty cases of local inflammation due to such causes would be met with to one due to septic absorption. He was in accord with Dr. Thomas, as expressed in a work published some years ago, regarding the peculiarities of the system of the puerperal woman. But he differed from the author in considering certain conditions which always followed normal labor as pathological conditions, which the speaker believed to be purely physiological. Certain quotations were made from that paper, going to show that the author regarded the lochia as an offensive fluid, made up of dead and decaying animal tissue, which poisoned the freshly-made and unprotected wounds that occurred during delivery. Dr. Barker asked the question, "Can it be true that the process necessary for the birth of the human race is always attended with the development of a deadly poison, whose malignant effects must inevitably prevent the spontaneous and kindly healing of such little traumatism as always result from the process, and that therefore it is the duty of the accoucheur to take preventive measures of the character proposed? Does every parturient woman, in performing the function of maternity, like the scorpion that carries in its tail an agent for suicide if death is threatened by fire, physiologically generate an equally fatal poison in a corresponding locality, which the obstetrician must guard against by means that are most inconvenient, alarming, and not altogether free from danger?"

He would not now discuss the question, which he had before thoroughly discussed, whether there was a distinct disease called puerperal fever, aside from puerperal septicæmia. But it was well known that epidemics of such a disease occurred in hospital practice, and at times in rural districts where, for twenty-five or more years, not a single death had occurred in childbirth except from the casualties of labor. All we know of any disease is derived from the study of its etiology, its clinical phenomena, and the anatomical lesions. Now, the epidemic disease to which he referred differed in all characteristic points from what was known as septicæmia. It differed in its origin, mode of attack, symptoms, and anatomical lesions. The symptoms were not infrequently manifest a day or two before labor, the child being subsequently born alive, whereas in septicæmia the symptoms were never manifest before or during labor unless the fœtus were putrid. Puerperal fever arose from epidemic causes, from contagion and infection,—the latter from nosocomial malaria, autogenetic infection, and direct inoculation. Now, every physician had probably seen cases in which a decomposing placenta had remained in the uterus for a longer or shorter time, and yet without septic infection taking place. Bad ventilation, contact of septic material, etc., it was true, had

a tendency to induce septicæmia in puerperal women as well as in surgical cases. But puerperal fever might develop from epidemic influences when the generally recognized causes of septicæmia were wholly wanting. In 1873 puerperal fever prevailed in certain of the best and wealthiest sections of the city of New York, while many of the filthiest and poorest districts, where influences which favor the development of septicæmia largely prevailed, were entirely, or almost entirely, exempt from puerperal fever; or, in the latter districts, the mortality from the disease was a third less than in the better neighborhoods. The patients whom he sent out of the city to be confined during this period all had a normal convalescence. Dr. Barker thought that those who studied the causes of puerperal fever from hospital practice exclusively must have one-sided and fallacious views. This was especially the case with persons brought constantly in contact with surgical septicæmia.

Dr. Barker then gave the hospital and general statistics of mortality from childbirth, going to show that exceedingly few women die from puerperal fever, and he thought it altogether improper, and even dangerous, to encourage the management of the woman about to be confined the same as a patient is to be treated who is about to undergo a capital operation: indeed, it would appear that if the importance were attached to Dr. Thomas's recommendations which he would seem to desire us to do, child-bearing ought to be made a penal offence in families whose income was not sufficient to enable them to carry out those requirements.

As to diagnosis, he did not regard the symptoms given by Dr. Thomas in their totality as pathognomonic of puerperal fever. They savored still too much of septicæmia. In private practice we had to treat the sequences of some form of blood-poisoning, which, however, was not necessarily septic poisoning; it was probably due, in the majority of cases occurring in private practice, to atmospheric influences, or to influences equally obscure in this as in other epidemic diseases. In the treatment, vaginal and uterine injections were of great service if the indications for their use were clearly seen in local signs, but they could not be recommended for every case on theoretical grounds and as preventive measures, as they might do harm by retarding cicatrization of slight lesions, by disturbing the patient, and parts which required rest, etc. Cases were related of puerperal fever in which the injections and the measures recommended in the paper by Dr. Thomas had been carried out, and after ceasing them, at Dr. Barker's suggestion, and substituting other measures, the temperature began at once to fall, and all the symptoms improved. His own experience with the methods advocated in that paper had not been favorable. Many years ago he tried them in several cases in Bellevue Hospital,

but they were given up, as they were less successful than other plans of treatment. Cold would do good in certain acute fevers, but in adynamic fevers it would do more harm in other respects than good by reducing the temperature. There was danger of pneumonia, and of other complications due to the weakening effect of continued cold when the patient's system was in this peculiar state. With regard to intra-uterine injections, it would be found, by turning to page 320 of his work on puerperal diseases, that he there, more than fifteen years ago, fully described methods for their employment. The method was employed in 1869, and published in 1874. The subject was also written upon and discussed at the American Gynecological Society before the meeting took place at which Dr. Thomas described and advocated the method. Unless he should yet learn new facts and new arguments to change his views there expressed, he should have to die impenitent.

After the reading of his paper, the President said that, in consequence of a large number of gentlemen having shown their willingness to take part in the discussion, gentlemen whom all present would be anxious to hear, he had felt bound to restrict himself to a limited time; and to content himself merely with the enunciation of general principles, which he believed to be important, without entering largely upon the discussion of details. But there was one point to which he would beg leave now to refer. It was important to know the results of one's own actual experience and his observations, and to know what were his individual convictions when discussing a subject of this nature.

"In the early part of my professional career I began the use of vaginal injections for one week after confinement, the antiseptic used being Labarraque's solution. Nearly thirty years ago, when I first entered upon duty at Bellevue Hospital, it became the invariable rule to make use of these injections of Labarraque's solution for one week after labor. Subsequently, when carbolic acid came into use, this was substituted for Labarraque's solution, and in the work before alluded to a formula for the use of these injections is distinctly and fully given. This formula I habitually followed, not only in hospital but in private practice, in almost every case, until within the past three years. In 1881, during the session of the National Medical Congress in London, at a dinner-party I happened to be seated next to Thomas Keith, of Edinburgh, and, as my rule is to draw out of others and appropriate all the information I can, as well as to give what I may be able to do myself, I became greatly interested in what he told me with regard to his experience and his conclusions concerning the use of antiseptics in ovariectomy. This conversation was very suggestive to me, al-

though nothing was said about antiseptic obstetrics, and led to great reflection on my part subsequently. I began to ask myself whether it was not possible that many of the interruptions and slight disturbances which I had observed to occur in my own obstetrical practice might not have been due to the carbolic acid. On returning, in the following September, to my practice again, I reduced the proportion of carbolic acid one-half, but still for a little time continued its use. But on further reflection, recalling the fact that, even in the strongest proportions in which I had used it, it was not sufficient to destroy the micrococci organisms which are supposed to be the real source of the disease which follows, I was led to ask myself whether it was not possible that nature had acted wisely in *bathing* with a fluid all the broken and lacerated tissues of the parturient canal, with that much maligned substance called lochia, and whether it was not more important to leave all this tract in perfect rest and quiet, as our surgeons tell us is practised in antiseptic surgery. Dr. Smith informs me that it was fully two years ago that I informed him that I should cease the routine use of vaginal injections after parturition. Since September, 1882, it has been my rule to direct, and I have often astonished my old nurses by the direction, never to use even vaginal injections unless they were expressly ordered; and this rule has been followed by my colleague and partner, Dr. A. A. Smith, and I am sure that he will sustain me in this assertion, that since September, 1882, not a single case has occurred in our practice with any interruption of the normal processes to give rise to any anxiety, or to call for more than our ordinary attendance,—namely, one visit daily for nine days. This result may be merely a happy and perhaps we may call it a lucky coincidence, but it seems to me significant, and I feel it a duty to state this fact, and I hope that those who may have applied such a test as this will give us the result of their observation and experience."

Dr. W. M. CHAMBERLAIN would only say a few words with reference to the tube which went by his name, and which had been referred to in Dr. Thomas's paper. He had not found the later tubes, three-eighths of an inch in diameter, too large; and one object which he had in view in making them of good size was that the anterior lip of the cervix might be raised with it at the time of the injection, thus giving free return-flow of the fluid. This suggested an important point in diagnosis in cases of puerperal septicæmia. He had never seen a case in which septic absorption had taken place from the uterus in which the cervical canal was not more or less patulous, and when it was not found patulous he was inclined to look elsewhere for the cause of the trouble.

Dr. H. T. HANKS read some remarks, and said that he believed that the paper read by

Dr. Thomas would have a most vital and lasting influence, and that many of the suggestions made by him would become the accepted rules of practice in the treatment of the puerperal patient. He thought the profession was willing to accept any plan which was likely to promise better results than those of the past. Dr. Hanks quoted certain statistics of the death-rate from puerperal fever in this city, and expressed it as his belief that had the methods of treatment suggested by Dr. Thomas been adopted, a great many lives would have been thereby saved. He himself had had no case, either in country or city practice, which he could not satisfactorily account for on the theory of septic poisoning. Regarding certain rules suggested by Dr. Thomas, he could not altogether agree. For instance, he would not make ante-partum vaginal injections. As to uterine injections, they should only be used when there was a strong probability that there was loose *débris* in the cavity of the uterus, which would be indicated, as stated by Dr. Chamberlain, by the partly-opened cervical canal. In confinement he insisted upon four assistants,—pure air, absolute quiet, judicious diet, and proper antiseptics.

Dr. W. T. LUSK thought that surgical septicæmia and puerperal fever were essentially the same process, and that much of the diversity of opinion on this point was due to a failure to take into consideration the different states of the system in the two conditions.
